### THE QUESTION OF AXILLARY OR ISCHIATIC SUPPORT IN THE TREATMENT OF JOINT DISEASES OF THE LOWER EXTREMITY.

BY A. B. JUDSON, M.D.,

NEW YORK.

(Read before the New York Academy of Medicine, June 16, 1881.)

AFFECTIONS of the joints of the lower extremity present some noticeable features of pathology, requiring corresponding peculiarities of treatment, when compared with similar affections occurring in the upper extremity. The exceptional pathological traits here alluded to, have their origin in the fact that the joints of the lower extremity are habitually exposed to great pressure in the standing position, which is on occasion maintained for long periods, and to the violence incident to the act of walking, violence which may well be termed momentous when the joints are called upon to endure the repeated and heavy blows inflicted by running. For the purposes of this paper, disease of the hip-joint, which has given rise to so many essays and discussions and surgical inventions, may be taken as the type of diseases of the joints of the lower extremity. Dr. Edmund Andrews, of Chicago, has portrayed the injury to which the diseased hip-joint is exposed by locomotion in the following words: "The synovial membrane, when inflamed, becomes roughened, yet upon this inflamed and rough surface the entire weight of the body presses, rubs, and grinds at every step. Of course under such harsh usage no tissue could be expected to recover without serious mischief, and especially the exquisite machinery of the joint."[1]

The assumption of the recumbent position at once removes from the joint this source of danger, and this resort has doubtless been made instinctively and by prescription ever since the earliest times of medicine and surgery. This position is a feature of some of the accepted modes of treatment of hip-disease, and it may be considered in many cases as contributing to their success. Its usefulness is limited by the fact that it cannot be maintained throughout the long period of an ordinary case of hip-disease, an affection which is almost invariably marked by long intervals in which the patient is free from pain, and, to all appearances, quite able to follow the ordinary pursuits of life.

The use of crutches, to facilitate locomotion and to prevent pain in diseases of the joints of the lower extremity, has also been commonly resorted to, in all probability since very early times. Their persistent and long-continued use was prescribed by Mr. Edward Ford. After referring to the advantages derived from the use of Le Vacher's apparatus for supporting some part of the weight of the head in caries of the cervical and upper dorsal vertebræ, he quaintly adds: "It would be fortunate if the knowledge of these circumstances could suggest any mechanical improvement calculated to produce the same beneficial effect in hip-disease; as nothing can be clearer, from rational manifest indications, than that the patient must feel ease and advantage, from every expedient to prevent the weight of the body, in any degree whatsoever, from pressing on the joint."[2] His mechanical resources began and ended with the use of crutches. The simplicity of his views and method even led him to condemn the attempts, which were in vogue at that time, to overcome the apparent shortening of the affected limb by adding a leaden weight to the sole of the shoe of the affected side. A few years later, Mr. Brodie wrote as follows: "If the disease (scrophulous disease of the joints) be in the lower extremity, he (the patient) should never rest the weight of the body on the foot belonging to it; he should never walk, except with the assistance of a crutch."[3]

Notwithstanding these authoritative prescriptions, crutches in the hands of a patient suffering from hip-disease have for many years been considered simply as means for facilitating locomotion—rather as insignia of the crippled condition than as instruments for the relief of pain and the promotion of recovery. Within a few years, however, the attention of the profession has been directed to the advantages to be derived from the continued use of crutches throughout the long period usually covered by the history of a case of this kind, and commendable attempts have been made to reduce to the minimum the inevitable inconveniences which attend their use. The ingenious apparatus of M. Mathieu is worthy of note. It consists of two axillary supports combined with a system of jointed rods which permit the patient to sit down, but which, when he assumes the erect position, transmit the weight of the trunk to the ground without allowing it to pass through the femurs.[4] This instrument is seldom, if ever, used in this country. It is our custom, when crutches are employed in the treatment of hip-disease, to raise the foot of the affected limb from the ground by giving a fictitious increase of length to the unaffected limb by the addition of an elevated sole to the shoe worn on that side. The earliest reference to this use of an elevated shoe and crutches, is found in a paper published by our eminent fellow, Dr. C. Fayette Taylor, in 1867, in which he says: "Indeed, many have advised—as I sometimes have when circumstances were such that nothing better could be done—patients to wear a thick sole on the foot of the *well* leg and use crutches, letting the lame leg hang. The only difficulty is in carrying the plan into practice with sufficient perseverance and uniformity."[5]

This device is an important feature of the method of Mr. Hugh Owen Thomas, of Liverpool.[6] It is also favorably mentioned by our honored fellow, Dr. Sayre, who, speaking of the treatment of hip-disease, says: "Another method is, in addition to the bed-extension, to make extension by increasing the

weight of the shoe worn upon the foot of the affected limb, and permitting the patient to go about on crutches. This can be done by running lead into the sole of the shoe. In such a case you will be obliged to increase the length of the sound leg by making the sole of the shoe considerably thicker." [7] Drs. John A. Wyeth [8] and Charles F. Stillman,[9] of this city, and Dr. De F. Willard,[10] of Philadelphia, have adopted crutches and an elevated shoe as features of their respective methods of treating hip-disease, and Dr. Richard J. Levis, also of Philadelphia, has ingeniously obviated the necessity of wearing an elevated shoe on the sound foot by flexing the knee of the affected limb and keeping it flexed with a silicate bandage.[11] The treatment of joint diseases of the lower extremity by the use of crutches or Darrach's wheel-crutch and an elevated shoe, has found a warm friend in our distinguished fellow, Dr. Joseph C. Hutchison. He prescribes this method in hip-disease to the almost complete exclusion of all other mechanical appliances.[12] It is due to his learned advocacy that this easy method is to-day very widely accepted as the simplest and most effective method of treating hip-disease. The question occurs whether the weapon is not too light and easily handled for successful combat with a foe so insidious, tenacious, and destructive.

The method of protecting the diseased hip, knee, or ankle-joint from pressure and concussion by the use of crutches transfers a large part of the weight of the body from the diseased joint to the axillary regions. The only alternative when the patient is erect, is to transfer this weight to the ischiatic tuberosity and the rami of the ischium and pubes. Throwing the weight of the body on to this region of the os innominatum in locomotion is not altogether a modern experiment. In Malaigne's "Paré" [13] may be seen a wood-cut representing a crutch for the relief of lameness resulting from a shortened limb. It has a curved projection, evidently designed to receive the upper part of the femur and the tuberosity of the ischium. The prothetic apparatus of MM. Mille and F. Martin [14] received the bones of the pelvis, and thus supported the weight of the body. Mr. Bigg says: "In the construction of the bucket of an artificial leg only one spot, the tuberosity of the ischium, exists where the bearing of the body can be correctly placed." [15]

M. Ferdinand Martin constructed an apparatus for the treatment of hip-disease, which is shown in Bonnet's "Therapeutics of Articular Diseases." [16] From this cut it is evident that the intention was to receive the weight of the body on two perineal straps attached to a pelvic band. This instrument was, however, discarded by its inventor, if a correct inference may be drawn from the fact that his more recent hip-splint is an entirely different apparatus.[17] M. Bonnet sought to make use of ischiatic support in the treatment of hip-disease, adapting for his purpose an instrument of Italian origin, in use at that time in the treatment of disease of the knee-joint. He was, however, discouraged by the difficulty in adjusting the apparatus, which arose from the adduction of the femur, and resorted to an instrument furnishing axillary support,[18] similar in its action to the jointed rods of M. Mathieu.

Dr. Henry G. Davis, although he modified the methods of this branch of surgery in very many important particulars, failed to produce an effective instrument for ischiatic support. His hip splint was described in April, 1860.[19] It had a perineal strap and extended to within a short distance above the outer malleolus. From his subsequent writings [20] it appears that he was of the opinion that this instrument received the weight of the body and transmitted it to the ground through the intervention of the patient's foot and the adhesive plaster attached to the limb. It is believed now that the adhesion of the plaster would be entirely incompetent to support the weight of the patient when erect and walking. This attempt therefore to provide ischiatic support, or to relieve the affected joint by allowing the weight of the body to rest upon a splint applied to the ischiatic tuberosity, was a failure, because the lower extremity of the splint fell short of reaching the ground.

Dr. Andrews was probably the first to solve the problem of efficient ischiatic support in joint diseases of the lower extremity. In December, 1860, he described a hip-splint, the upper part of which was (to use his own language) "a crutch top well padded, which rests against the perineum." He wrote that when the splint is applied, "the weight of the patient rests upon the instrument, and the instrument upon the ground." [21] In the following year, describing this splint, he wrote: "The top supports the perineum by a crutch-piece, padded and covered with patent leather, and the bottom is attached firmly to the sole of the shoe, and at each step transmits the weight of the body directly to the ground." [22] In 1866, Dr. David Prince, of Jacksonville, Ill., described an inexpensive and rude, but probably efficient modification of Dr. Andrews' apparatus, [23] and in 1867 Dr. Taylor described the hip-splint which is widely and justly called by his name.[24] It is so well known that a description here the weight of the body in standing from the joint to is unnecessary. As an apparatus for removing the inferior surfaces of the ischium and pubes, the features which distinguish it from the instruments of both Drs. Davis and Andrews are found in the presence of a pelvic band, and in the fact that it is provided with two perineal straps instead of one. Drawing my inferences solely from the published literature of the subject, the splint in question appears to be the result of an evolution in which may be traced the following steps.

We have, first, the portative splint of Dr. Davis, reaching not below the ankle, with but one perineal strap, and without a pelvic band. Then we have Dr. Andrews' splint, reaching to the ground, and acting against the perineum of only one side. Then we have Dr. Sayre's short splint, reaching not below the knee, with one perineal strap and without a pelvic band. [25] Then we have a pelvic band of limited length, and carrying, as yet, but a single perineal strap attached by Dr. Taylor, first to the short splint of Dr. Sayre,[26] and then to the splint of Dr.

Davis.[27] Finally, we have Dr. Taylor's splint, described by him in 1867, as it remains, without radical change, to the present time, reaching to the ground and provided with a band including a large part of the circumference of the pelvis, and carrying two perineal straps. Viewing it solely as an instrument for ischiatic support, and closing our eyes to its important and beneficent action as an instrument for the application of extension and counter-extension, this apparatus is a rare example of the successful adaptation of simple means to an important end.

Leaving out of view other and more important uses or functions of the hip-splint, it may be considered as a pair of crutches applied to the ischiatic or perineal, instead of to the axillary regions. Viewed thus as an appliance for averting pressure and concussion from the joint in the acts of standing and walking, how does the hip-splint compare with the other methods in use for effecting this object?

It is better than the recumbent position, not because it fortifies the general health of the patient by permitting exercise, for evidence is not wanting that the general condition is improved in many cases by persistence in the recumbent position, but because this position cannot be enforced through the duration of an ordinary case. The incipient and convalescent stages are, in many cases, not only of great duration, but also of great freedom from pain. In these stages it is impracticable, from the nature of the case, to enforce the recumbent position, while the hip-splint can be worn, with little inconvenience, for months and years, securing protection from pressure and concussion, permitting wide liberty in locomotion, and enabling the patient to follow the ordinary pursuits of life.

It is better than the use of crutches, either with or without the elevated shoe, for several reasons. Not the least of these is found in the fact that locomotion with crutches requires the use of both hands, while with the hip-splint the hands and arms of the patient are as much unoccupied as though he were entirely free from encumbrance. Again, the hip-splint is ever present, while crutches may be mislaid or temporarily discarded, especially if the patient is free from pain and averse to their use. Finally, a strong argument in favor of the superiority of the hip-splint when compared with the use of crutches, is found in a consideration of the anatomy and physiology of the parts of the body which are involved. The axillary region, from the softness of its structures, from the presence of the brachial plexus, and from the absence of a firm osseous connection between the upper extremity and the trunk, is painfully ill-adapted to the duty of supporting the weight of the body in locomotion; while the ischiatic region, which receives the perineal straps of the hip-splint, is accustomed to bear the weight of the body in sitting, and is recognized as peculiarly adapted for this purpose by the basilar character of the bones of the pelvis.

Dr. Taylor, describing this use of the hip-splint, writes: "The patient sits firmly upon the padded straps, which, passing under the ischia and perineum, are attached to the pelvic band in front and behind."[28] Although the patient is erect, the word *sit* is perfectly correct in this connection, because the patient's weight rests on the ischiatic tuberosities, the seat-bones, as they are termed by horsemen, as truly as if he were sitting on a chair. Observation of a patient thus equipped, and walking without assistance, shows that progression is made by alternately throwing the weight on the unaffected limb and on the perineal straps, the affected limb being suspended, or, at most, touching the ground lightly with the toes. When the patient is erect, and divides his weight between the sound limb and the splint, he doubtless experiences a combination of the sensations of sitting and standing, and it is not altogether fanciful to say that in walking or running he alternately takes a step and sits down, taking a step with the sound limb and then sitting on the perineal straps. It is related of a bright little boy, to whom this splint was applied, that he immediately walked gaily about the room, exclaiming, at the same time: "I'm sitting down." It is not to be inferred from this fable that locomotion with the hip-splint is at once performed easily and gracefully. It is a difficult apparatus to adjust or to learn to wear with satisfaction. But that it is successfully applied in a large number of cases, and does not very seriously interfere with locomotion, is sufficiently obvious on the thoroughfares of this city. Mr. William Adams, on his return to London, reported upon what he was pleased to call the "American idea" in the treatment of hip-disease, and said, in reference to the hip-splint: "Children with hip-joint disease in a more chronic form are frequently seen walking about the streets of New York wearing these supports, and are enabled to get in and out of the tramway cars without difficulty."[29] As an instance of the degree of ability that may be enjoyed by a person wearing this apparatus, I may cite the case of a patient suffering from hip-disease who has worn a splint, with an elevated shoe on the foot of the sound side for the past two years, holding at the same time an appointment as teacher in one of the public schools, and performing all the duties of her position. She walks without crutch or cane, and without touching the ground with the toes of the affected limb, and goes about the city by the elevated roads, or otherwise, without assistance.

Preventing the foot from contact with the ground in locomotion converts the limb into a pendent member. It then hangs from the trunk as the arm swings at the side, its joints receiving no more pressure or concussion than the joints of the upper extremity. This disposition eliminates from diseases of the joints of the lower extremity the exceptional pathological traits which distinguish them from the corresponding affections of the joints of the upper extremity.

Practically, it is important to have the hip-splint made sufficiently strong, especially in the pelvic band, which supports the perineal straps at a great disadvantage, to sustain without yielding the weight of the patient. It will be found necessary to combat the very natural and common prejudice against applying a heavy and unyielding instrument to a feeble and suffering patient. But it may be borne in mind that, during a large part of the time when the patient is erect, the splint is resting on the ground, when it may be said that the splint carries the patient instead of being carried by him.

# INOCULATION OF BOTH EYES FOR COMPLETE PANNUS WITH GONORRHŒAL PUS.

## Recovery of Sight after Eleven Years of Blindness.*

By E. S. PECK, M.D.,

Aural Surgeon to the Metropolitan Throat Hospital; Visiting-Surgeon to the Charity Hospital.

The following clinical notes of a very interesting case of pannus crassus were furnished by Dr. Steers, house surgeon in charge of the ophthalmic division of the Charity Hospital at that time. They are offered for publication both on account of the bold measures employed in treatment, and of the happy results obtained.

TRACHOMA— PANNUS (BOTH)—INOCULATION.

John Smith, aged twenty-one years, single, born in the United States, worker in varnish, entered the eye ward of Charity Hospital, Blackwell's Island, October 18, 1880.

*History.*—Patient came to hospital suffering from trachomatous pannus in both eyes; duration in the right eye four years, in the left eleven years. He attributes this trouble to use of dirty towels at an orphan asylum in which he passed a portion of his boyhood. On admission, patient could merely make his way around the ward; sight of right eye was better than that of left. Patient was ordered to bed, with constant application of hot compresses night and day; also a solution of nitrate of silver, gr. xx., ad. aq. ʒj. twice daily to the inner lid surfaces and cornea.

November 30th.—Condition improved as to pain, tumefaction, and infiltration of lids, but no improvement in vision.

December 4th.—Treatment by inoculation was resorted to. First experiment: Pus was taken from a long suppurating wound behind the ear; wound secretes healthy pus; was made by Dr. Peck for the purpose of connecting two post-aural sinuses situated one above the other, four and one-half inches. This pus was rubbed over the cornea of the right eye.

December 7th.—No evidences of any acute inflammatory reaction were present. Second experiment: On the same day pus was taken from the eye of an adult in Ward 7, female, ophthalmic division, suffering with purulent ophthalmia. Pus was injected by means of an hypodermic syringe beneath the conjunctiva of lower right lid. Owing to the movements of the patient, injection was not as successful as could be desired.

December 10th.—No signs of inflammation. Third experiment: Matter was now taken from a recent case of ophthalmia neonatorum in Ward 7, female, and rubbed across the cornea of the right eye.

December 14th.—No signs of inflammatory reaction; and, as a fourth experiment, it was determined to use gonorrhœal pus. A fresh case, of seven days' discharge, was found in one of the male venereal wards. Two drops were applied by means of the finger to the cornea and conjunctiva of the right eye. Orders were given to let it entirely alone, and not to protect the left eye.

December 15th.—Within ten hours after the attempt at inoculation the right eye showed all the signs of an acute ophthalmia. No dressings were ordered, and the disease was left to run its course.

December 16th.—On this, the following day, the left eye developed the same characters of inflammation.

December 25th.—Copious discharge of a creamy, yellow pus from both eyes. Patient complains of considerable pain under the lids.

January 4, 1881.—Ordered a solution of nitrate of silver, gr. x., ad. aq. ʒj., three days of the week, and the same solution, gr. v., ad. aq. ʒj., four days of the week, with constant application of iced-cloths.

Patient was discharged from the hospital at his own request in March, and visited me at the Northwestern Dispensary, April 10th, when a careful examination gave him for vision as follows: Right eye, four years blind and inoculated, V = finger-counting at nine feet; left eye, eleven years blind, inoculated by infection, V = fingers at one and a half feet.

Patient has engaged himself at a livery-stable as hostler, and states that his sight for this purpose is sufficient, and that he suffers no pain nor tenderness. In the right eye the iris and pupil are plainly to be seen.

*Remarks.*—It is a subject of pertinent inquiry whether it be good surgery to undertake so bold a measure as the implantation of inoculable pus of a virulent type in an organ endowed in the first place with a rich system of lymphatic conduits; and, second, whose function is that of a special sense. To this there may be made answer in the category which Mr. Bader* adduces—that is to say, matter may be selected in the following order with regard to the safety of inoculation.

I. Pus taken from a purulent ophthalmia of the infant in a stage of decline of the pyogenic process, and where the cornea had not been perforated.

II. Pus from a purulent ophthalmia of the infant, whose mother suffered from a slight yellow vaginal discharge.

III. Pus from the same, whose mother suffered from gonorrhœa, or whose eyes had coexistent gonorrhœal ophthalmia.

IV. Gonorrhœal pus in the acute stage.

It will be observed that pus was selected with some regard to this series; the exact material, as stated by Mr. Bader, was not at hand.

It is to be remembered that the more vascular the cornea, or the more sarcous the pannus, the better the results; so too in these severer cases, pus of a higher septic quality may be used. The chief danger with gonorrhœal pus is not, however, its virulence, but the possible concealment of a venereal sore upon the part from which the pus is taken. Such an accident would be grave in its consequences. It would surely premise a perforating ulcer of the cornea, if it did not entail syphilis.

On this point Mr. George Lawson,† who, with Mr. Bader, has made extensive experiments with cases of granular conjunctivitis and pannus, writes: "It is best that the pus should be always in the first instance taken from the eye of an infant suffering from purulent ophthalmia, as it seems to me that, although gonorrhœal matter may, in extreme cases, answer very well, yet there is always a certain amount of risk as to its purity, whether some syphilitic virus may not accompany it; for, since a chancre in the urethra is occasionally associated with gonorrhœa, it is difficult, if not impossible, to say that the patient from whom the matter is derived is free from it. I prefer, for this reason, always to take it from the child."

Another danger to be feared is the establishment

* Paper read at the semi-annual meeting of the Vermont State Medical Society, June 25, 1881.

* Reports of Royal London Ophthalmic Hospital, vol. iv. p. 30. 1863-65.

† Ibid., p. 183.

of diphtheritic instead of purulent ophthalmia. As diphtheria has special habitats, this danger is more to be feared in certain countries than others. In England and certain portions of our own country, inoculation is rarely followed by diphtheria; whereas in Northern Germany it is of frequent occurrence as a complication of ophthalmia; hence, in Germany the procedure is unpopular; while Graefe would not allow its introduction in his Berlin clinic. Stellwag * accords it the place of an heroic remedy, to be used after other methods have failed; while at the same time he testifies to its successful and surprising results in the treatment of pannus.

The best success has resulted with eyes where the cornea has been very vascular, the pupil and iris being scarcely visible. As was noted above, these eyes may be inoculated with the strongest pus in the series. Mr. Lawson states that such eyes will almost invariably recover, and good useful sight be regained. Another important point is that pus increases in virulence in its travel: so that a third eye will receive stronger pus from the second eye than this received from the first. Of the one hundred and seventy eyes inoculated by Mr. Bader, two corneæ were entirely lost, and ten were perforated by the suppurative process.

Wecker,† of Paris, "though not generally deficient in boldness"—so he writes of himself—has never as yet ventured on this proceeding, whose results could not be foreseen. In the severe cases of vascular pannus he prefers abrasion of the conjunctiva and warm compresses. He asserts, with a touch of vanity, that in his clinique in the Rue du Cherche Midi there are only two to three per cent. of granulation cases, whereas in some of the Paris dispensaries the proportion runs as high as fifteen per cent. It is questionable whether the social standing of patients alone determines the frequency of trachoma. In North Germany, the disease is much more prevalent than in Bavaria, as the author of this paper is personally aware. In certain large Bavarian towns trachoma is a great rarity; so much so, that a story is told of its introduction into Bamberg, a few years ago, by a *conducteur* on one of the South German railways. In England, it is one of the most common eye diseases.

In cases of monocular pannus, inoculation may be questionable. If it be determined on, the sound eye must be firmly sealed with gum-mastic, cotton, and a bandage, or with the watch-glass "blinder," made fast with diachylon plaster and collodion. Great care must be used in changing the dressings and cleansing the eye, and every change should be made as speedily as possible. Buller's shield, a picture of which is seen in Mr. Lawson's book on "Diseases and Injuries of the Eye," is one of the best sealing bandages I know of.

Finally, I desire to impress upon those interested in this method of treatment of cases of pannus that, where the cornea is dry, whitish, or in the condition of confirmed staphyloma, where there is not a well-pronounced vascularity of its superficies, and where also granulations of the conjunctival surfaces are wanting, inoculation will not only be unsatisfactory, but may be dangerous. But, with these latter conditions well exemplified, I should not hesitate to employ this bold means after all other plans of treatment had failed to restore sight.

In addition to the references already made, the author would refer to the following sources of earlier literature on this subject: Piringer: "Blennorrhœa in the Human Eye," Gratz, 1841; v. Roosbroeck: "Cours d'ophthalmologie," vol. i., p. 566; Warlomont: *Annales d'Oculistique*, xxxii., p. 149; Ludwig: *Tubinger Blätter f. Naturwissensch. u. Arzneikunde.* Band. II., H. 2.

## ADENITIS AND ANGIOLEUCITIS OF THE PELVIC CELLULAR TISSUE.

By J. S. CARREAU, M.D.,
NEW YORK.

Dr. Leopold, of Berlin, in 1873, has minutely described the lymphatics of the pelvic cellular tissue. He says that the mucous membrane of the uterus is very extensively supplied with lymphatics, existing in the form of sinuses, separated from each other by the endothelia. These sinuses are connected into the form of infundibula, which create a communication with the lymphatics of the muscular coat. The sinuses exist in the muscles, but as soon as they reach the peritoneum, they lose all appearances of sinuses, and form irregular plexuses on the anterior and posterior parts of the organ. In these plexuses lymphatic ganglia exist, being situated mostly in the broad ligaments and cul-de-sacs.

Cruveilhier, in his "Atlas of General Pathology," has shown some of these ganglia filled with pus, after confinement.

Dr. Courty, in the April number of the *Annales de Gynecologie*, has ably described a disease called peri-uterine adenitis, bringing forward some clinical cases and a few post-mortem examinations of the same.

Countenanced by such high authorities, I presume to report a few cases, which I shall term pelvic-adenitis and angioleucitis.

Mrs. E——, aged thirty-two, married five years, had one child and one miscarriage of three months old. She is of a lymphatic diathesis; has been brought up in luxury; had obstructive dysmenorrhœa since her first menses; was operated upon for anteflexion, and the result was favorable; became pregnant a short time after marriage; had a long labor, the child living, but very weak. From that time up to June, 1879, she has been suffering now and then from local and general symptoms; consequently had been under medical treatment during that period. From June, 1879, to February, 1880, when she again became pregnant, she felt remarkably well. Although her uterus was not yet in a perfect condition during the time she carried the child, she had her menses when they ought to have been suppressed. Up to June, 1880, when she started for the country, the diagnosis of pregnancy was only approximately made from constitutional symptoms. In July she had a three months' miscarriage, from which she apparently speedily recovered. About ten days after the miscarriage she became unable to walk, complaining of pain localized in the lower part of the sacrum and left inguinal region, rectal and vesical tenesmus; in a word, all the symptoms of peri-uterine inflammation were present except high fever. One month after the miscarriage I saw her. Physical exploration was made. Two little nodules were felt in the upper part of the vagina, one in the posterior cul-de-sac, the other toward the left broad ligament, round, immovable; excessively tender to the touch; no tenderness in the parts adjacent to the nodules. The uterus was movable, and the cer-

vix bathed in purulent matter. Sometimes the finger would fail to detect these nodules. The hand placed on the abdomen, in conjoined manipulation, would push them further down in the vagina so as to be felt by the finger. The first thing to be done was to ascertain what it was I had to deal with. Prolapsed ovary was out of the question, for the following reasons: It was not probable that both ovaries would be prolapsed at once; and these nodules were too small to be mistaken for ovaries. A prolapsed ovary is also more movable, unless bound by peri-uterine inflammation. In peri-uterine inflammation the uterus is immovable; the pain is more general; no nodules are felt separated from each other by healthy tissue. As to hæmatocele and tumors, they cannot be mistaken for pelvic adenites. These were the same symptoms she had after confinement; was treated for pelvic-cellulitis; suffered more or less during a period of nearly a year. This time a different diagnosis was made, and accordingly treatment suited to the case was followed. Large, hot-water vaginal injections were given morning and evening; fifty per cent. solutions of carbolic acid were applied to the uterine cavity every second day; mercurial ointment with belladonna constantly kept over the pubes; outdoor exercise every day, but not to the point of fatigue. Besides all this, her constitution was brought to its highest condition by a generous diet, with Burgundy wine, or English ale, and daily sponge-baths, followed by good, coarse towel-rubbing. In October she was entirely recovered; had no pain whatever; her menses normal; appetite, digestion, and sleep good.

Mrs. M——, aged thirty-eight, born in Germany, married ten years, had six miscarriages; one premature child, which died when two months old of syphilitic pemphigus; and another, a full-time child, which is living and well. All these miscarriages ranged from two to four months, the last one three. She contracted the disease from her husband, and her first symptoms were that of papula syphilitica, coming on a few weeks after the first miscarriage. I first saw her when she had her last miscarriage, which was in June, 1878. This miscarriage was followed by the following symptoms: Pain in sacrum and left side, extending down the thigh; fecal evacuation unbearable. All these symptoms were greatly increased when standing or walking. Physical exploration revealed a few small nodules in the upper part of the vagina, as described in the previous case; the uterus was in its proper axis, and not tender to the touch. A small nodule was also felt in the walls of the abdomen one inch below and to the left of the umbilicus, which was movable and very tender; she had also a few papules on the body and extremities. Certain of the diagnosis, I put her under the mixed anti-syphilitic treatment, and, to my great satisfaction, in less than three weeks all these symptoms and growths, which I feared would compel her to keep in bed many weeks, were banished. Having entirely recovered, I lost track of her until February, 1879, when she was seized with her old malady; she was then three months pregnant. She had a single nodule in the walls of the abdomen, although none could be felt in the cul-de-sac; it is true, my explorations were not minutely accurate. Large doses of potass and mercury at once removed all the symptoms. After having discontinued the treatment for many months, she gave birth in July to an eight-months child, which died when two months old. From that time to the present she has followed the usual treatment, and the result was favorable. She had in December, 1880, given birth to a child which is living and strong. She had a perfectly normal labor, with none of the old complications. She had, while under my care, three severe attacks of what might be called peri-uterine inflammation, and each attack was subdued by the mixed treatment and the application of mercurial ointment above the pubes.

Mary Ann ——, aged twenty-seven, single, school teacher, came to me in June, 1879. She had then general adenitis and constitutional dysmenorrhœa. Born of scrofulous parents. Previous to 1878 her menstruations were perfectly normal, but as to her adenitis it had been getting worse and worse for some time past, and especially since 1878, when her menses began to be both painful and scanty. She had been educated in a boarding-school, where she studied very hard, and would spend her hours of recreation at work. She says that her years of school have very much contributed to make her what she is now. On account of the increasing severity of the dysmenorrhœa and of the vesical and rectal-tenesmus, I made a physical exploration and found the uterus in its normal axis; but in the cul-de-sacs small nodules, tender to the touch and immovable, were felt, and also bands of indurated tissue could be mapped by the finger. On account of the general adenitis and of the increased pelvic symptoms, when her constitution was on the decrease, it was natural to infer that I had a case of pelvic-angioleucitis and adenitis. The treatment has been successful. She went into the country, worked like a farm-girl, followed a milk diet, and took daily salt sponge-baths, and, in a word, brought her constitution by general training and constitutional care to its highest point. In September, 1880, came back to New York approximately well. Her menstruations are perfectly normal; all pelvic symptoms are banished; her general adenitis is mostly well, except a few enlarged cervical glands. Her appetite is voracious, and she can digest any kind of food.

I have selected these three cases, and have followed their clinical history very carefully. If they had been treated as simple cases of pelvic-peritonitis or cellulitis no doubt the results would have been very unsatisfactory.

## THE NEW YORK STATUTES FOR REGULATING THE PRACTICE OF PHYSIC AND SURGERY.

By EDWARD B. MERRILL,

ATTORNEY AND COUNSELLOR-AT-LAW, NEW YORK.

The discussion upon the question of what is the legal meaning of chap. 513, Laws of 1880, entitled "An Act to regulate the licensing of physicians and surgeons," passed May 29, 1880, demands further elaboration. The literary and grammatical features of the act have been already justly commented upon. In the present article we will, in as brief space as possible, examine the historical legislation of this State with regard to regulating the practice of medicine and surgery here. These acts are various, beginning as far back as 1760, with regard to medical practice in the city of New York, and coming down to the current year. The acts were originally passed, and, as for that matter, are now, for the protection of the public from the pretensions and fraudulent practices of charlatans, impostors, and quacks. Whether they are the best that can be devised, or even as good as those of an earlier date, and as likely to be effectual as those were; or

whether an act which entirely left out of its purview all connection with informers, and all punishment of a criminal nature, as both being demoralizing and difficult of enforcement; or whether some parts of the old and the new acts could not be combined in another act, and made easier for both the public and the offender, and still perfectly effectual for the purpose desired, are questions which doubtless have been fully considered by the projectors of this act, and deemed impolitic to attempt. At any rate, whatever may be our private opinion, they are foreign to the present occasion.

Legislation of this character is no new thing. As far back as the year 1511-12 an act was passed for the registration of physicians and surgeons in England and Wales, 3 Henry VIII., chap. xi. This act was amended from time to time (seven times only), down to the year 1858, when the present Medical Act of Great Britain and Ireland was passed, 21 and 22 Victoria, chap. xc. This now stands as their present Medical Act (see "The Medical Practitioner's Legal Guide; or, The Laws Relating to the Medical Profession," by Hugh Wightman, Esq., M A., Cantab. London, 1870).

The late Ch. J. Redfield, in a case reported in the "Vermont Reports" (12 Vermont, 146), in speaking of these acts says: "The history of legislation, in regard to apothecaries, surgeons, and physicians, from the date of the statute 14 Henry III., when the subject was first attempted to be regulated by law in England, to the present time, would afford a curious subject of investigation, and might tend in some degree to throw light upon the present question. The College of Physicians was incorporated there as early as 14 Henry VI., with most enormous powers, both of restriction and coercion in relation to all who attempted either of the above named acts. And it still seems to be supposed there that much harm may be prevented by these legislative restrictions."

It is too late now to discuss with any profit, or with any hope of change, the question of the policy of such legislation. That is too well approved by the laws which have been passed, by the decisions of the courts, and by the intelligence of the public. The constitutionality of such laws in their general scope has also been determined by the Supreme Courts of Massachusetts, Nevada, New York, Ohio, and other States.

The first section of the present act divides into three classes those physicians and surgeons who are permitted to practise here, by providing: "1st, a person shall not practise physic or surgery within the State unless he is twenty-one years of age, and either has been heretofore authorized so to do, pursuant to the laws in force at the time of his authorization; or, 2d, is hereafter authorized so to do as prescribed by chapter seven hundred and forty-six of the laws of eighteen hundred and seventy-two; or, 3d, by subsequent sections of this act."

Section 2 provides, among other things, that all three classes shall register, etc.

Let us now examine, as briefly as we may, the legislation in this State upon the subject, with a reference to some of the decisions of the courts under the old statutes now repealed.

The practice of physic and surgery in the city of New York was first regulated June 10, 1760 (vide L. and S., vol. ii., 188; V. S., vol. i., 382), and afterward by an act of March 27, 1792 (vide Gr. vol. ii., 425).

The first act was entitled, "An Act to regulate the practice of Physic and Surgery in the City of New York, Chaps. cxcviii, passed the 10th June, 1760."

The preamble gives in quaint phrase, but with explicit freedom of expression, the reason and philosophy of all the legislation on the subject, and is as follows:

"Whereas many ignorant and unskilful Persons in Physick and Surgery, in order to gain a Subsistence, do take upon themselves to administer Physick and practice Surgery in the City of New York to the endangering of the Lives and Limbs of their Patients; and many poor and ignorant Persons inhabiting the said City, who have been persuaded to become their Patients, have been great Sufferers thereby,

"For preventing such Abuses for the future:

"1. Be it enacted, by his Honour the Lieutenant Governor, the Council, and the General Assembly, and it is hereby enacted by the authority of the same, That from and after the Publication of this Act, no Person whatsoever shall practise as a Physician or Surgeon in the said City of New York, before he shall first have been examined in Physick or Surgery, and approved of and admitted by one of his Majesty's Council, the Judges of the Supreme Court, the King's Attorney General, and the Mayor of the City of New York for the time being, or by any three or more of them, taking to their assistance for such examination, such proper Person or Persons as they in their Discretion shall think fit. And if any Candidate, after due Examination of his Learning and Skill in Physick or Surgery as aforesaid, shall be approved, and admitted to practice as a Physician or Surgeon, or both, the said Examiners, or any three or more of them, shall give, under their hands and seals, to the Person so admitted as aforesaid, a Testimonial of his Examination and Admission in the Form following, to wit:"

Then follows the form of the testimonial.

"Section 2 provides that Persons practising either Faculty, without such Testimonial, to forfeit Five Pounds; Provided, that the Act does not apply to those Persons practising either Faculty before the Publication of this Act, or to any Persons bearing his Majesty's Commission, and Employed in his Service as a Physician or Surgeon."

On March 23, 1797, the first general regulation throughout the State was adopted, authorizing the Chancellor, a judge of the Supreme Court or Common Pleas, or a Master in Chancery, to license physicians and surgeons on receiving evidence of their having studied two years, etc., and the act of March, 27, 1792, was thereby repealed (vide Gr., vol. iii., 417, 419).

This act of March 23, 1797 was revised, and with some alterations passed April 4, 1801 (vide K. & R., vol. i., 449).

It was further amended in one of its provisions March 22, 1803 (vide W., vol. iii., 334).

On April 4, 1806, an act was passed establishing medical societies in the State, and a general State Medical Society, and repealing the former act (vide W., vol. iv., 537). This act, with its subsequent amendments, has been adopted in the present revised act (note to chap. xciv., 2 R. L., 219; Van Ness & W.. Rev. of 1813).

2 R. L., 219, was amended by laws of 1818, ch. ccvi., p. 192. In this act censors are appointed by the county medical societies to examine students, etc., and also in act of 1818.

One of the earliest decisions under this act was by the Supreme Court in 1817, entitled Timmerman v.

Morrison, 14 Johns. R., 369. This was an action brought in a justice's court to recover for medicines sold to, and for attendance upon, defendant's family in sickness. The Court says: "The justice erred in his construction of the statute *for regulating* the practice of physic and surgery" (2 R. L., 219). "The twelfth section of that act forbids any person to practise physic or surgery without a diploma, and declares that 'if any person shall so practice without a diploma, he shall forever thereafter be disqualified from collecting any debt incurred by such practice in any Court in this State.' The twentieth section superadds a penalty of twenty-five dollars for practising without a regular license, with a *proviso* that 'no person shall be subject to such penalty who practices without fee or reward;' and with the further *proviso* that 'nothing in this act contained shall be construed to extend to debar any person from using or applying for the benefit of any sick person, any roots, bark, or herbs, the growth or produce of the United States.' The true construction of all these sections and provisos, taken together, is that no person *commencing* to practise without a licence, after the date of the act, shall be capable of suing for services rendered, or medicines furnished as a physician or surgeon; and that every person so practising without licence is subject to the penalty of twenty-five dollars, unless he proves that he practised gratuitously, or that he administered only roots, bark, or herbs, *the growth or produce of the United States.*"

Another case arose in October, 1828, and is reported as Allcott *v.* Barber (1 Wend., 526).

Barber sued Allcott in a justice's court for botanical medicines furnished for his daughter at three different times in the year 1824, amounting to eighteen dollars. Allcott pleaded, generally, that he didn't owe him anything, and specially: 1st, that Barber was not a licensed physician; 2d, that Barber did not use for the benefit of Allcott any roots, etc., the growth or produce of the United States; and 3d, that Barber's services and medicines were useless, etc. Upon the trial it appeared that a daughter of Allcott was ill of a complaint which had baffled the skill of her attending physician; that Barber was sent for to come from Auburn, where he resided, to Rochester, a distance of seventy miles; that he visited the patient three times, in the summer, in the fall, and at an intermediate time; that he left to be used by the patient, two phials of medicine and a box of ointment; that the patient was recovered, or nearly so, by the use of the medicine. What the medicine was the witness did not know.

It was proved by Allcott, the defendant, that the plaintiff, Barber, went about the country administering medicines and prescribing for diseases, and was not a licensed physician.

The Court, Savage, Ch. J., says: "This case seems to be an attempt to evade the statute which prohibits a recovery by a medical practitioner who is not regularly licensed. . . . . Where the same person officiates as physician and apothecary he comes within the decision of this court, that an unlicensed practitioner is incapable of suing for services rendered, or medicines furnished, as a physician. As the patient was cured, it is to be regretted that Barber was not paid; but if unlicensed pretenders to skill in diseases can recover, as in this case, the statute may become a dead letter; the country will be filled with mere quacks, peddling their nostrums, and deceiving and destroying the ignorant and credulous—the very mischief which the statute is intended to prevent. I do not say that the defendant in error is a mere pretender, for he cured his patient, and in honor and honesty should have been paid; but it is our duty to administer the law," etc.

Another case arose in 1840, entitled McPherson *v.* Cheadell (24 Wend., 15, 1840). In this case, Dr. Elijah Cheadell sued McPherson, in 1837, for services rendered as a physician, and for medicines furnished from 1803 to 1836. The defendant pleaded the *general issue*, and the *statute of limitations*. The case was heard by referees, and afterward the record was brought to the Supreme Court for review.

In the opinion of the court, by Judge Cowen, the effect of the several acts of the Legislature regulating the practice of physic and surgery upon the rights of physicians is considered and commented on. We give only such extracts from the opinion as relate to our general topic, p. 24: "In the first place, I doubt much whether the defendant below, after retaining the plaintiff as a physician, and accepting his services as such, could call upon him in the first instance to prove a regular *license*. In other like cases the presumption is against the defendant. It is so between attorney and client in a suit for services performed under a retainer. There, if the objection sound in the fact that the plaintiff was never admitted, or that his admission has become inoperative, it lies with the defendant to show it. Besides, the contrary would be doing great violence to the presumption that no man will transgress the command of a positive law.

"The plaintiff had practised some forty years, at least, and for much of this period there was a penalty collectible from any one who practised without a license, and such an act was for the whole period contrary to the statute. He could not collect the wages of his practice. . . . .

"But if the plaintiff be put to the strictest proof, how will he then stand? He produced a regular license under the Act of March 23, 1797 (3 Greenlf., 417, § 1). That act required him to produce satisfactory evidence to some judge of the Common Pleas of this State, or other officer mentioned, that he had practised physic, or surgery, or both, for the term of two years previous to October 1, 1797, or satisfactory evidence that he had studied, etc. It also required him to obtain a certificate of such satisfactory evidence from the officer, under his hand and seal, file it with the clerk of the county where he resided, and take a certified copy, subscribed by the clerk, or otherwise he incurred a penalty of $25 for every act of professional practice.

"Proof was offered by an unofficial certificate that the doctor was a member of the county society formed in 1806, under the statute of that year (chap. 138, § 1, revised and re-enacted 2 R. L. 1813, p. 219—see note there). In 1818, Sess. 8 of that year, chap 206, the Act of 1813 was amended, and, among other things, every practitioner of medicine was required to attach himself to the medical society of his county by lodging his certificate with the president (§ 7). What consequences should follow the omission is not declared. The certificates were disregarded by the referees, and parole evidence was received of his having been a member of the county society for a number of years. The court says: 'But this veteran practitioner having, as he believed, fought his way through the adverse legislation of nearly half a century, it is thought must, at all events, surrender a part of his claim under the new and point-blank provision which found its way among

the numerous alterations introduced into the revision of 1830 (1 R. S., 450, 2d ed., § 16). This section provides that no person shall practise physic or surgery unless he shall have received a license or diploma for that purpose from one of the incorporated medical societies in this State, or the degree of Doctor of Medicine, etc., or shall have been duly authorized in a certain form under the laws of some other State or country. The doctor produced no license or diploma from any society. His certificates, it was objected, were neither of them technically such, and if a license was necessary, he could only resort to the certificate of 1797. This latter was substantially according to the law of that day, and conferred a right which continued for life, unless divested by some disfranchising statute. The provision in the Revised Statutes is general. It prohibits *all persons* practising unless they have the license required. It is not in terms confined to persons taking licenses after 1806, when, for the first time, medical corporations could be formed; nor does it expressly say it means not to touch those who were previously licensed. There are classes to whom it may be equitably applied, probably most persons now in practice, for the granting of corporate licenses or diplomas commenced so early as 1806 (vide Sess. L. of that year, chap. 138, § 4), and was continued in the subsequent acts (vide 2 R. L. of 1813, 221, § 9 and § 21). To these latter persons, according to the same rules of construction, it should be confined; and we think might be, if necessary. The statute can have ample scope without working injustice to any one. Dash *v.* Van Kleeck (7 Johns, 477), and the cases there cited, will be found full to the point that it should be so construed as not to interfere with previously vested rights.

"Timmerman *v.* Morrison (14 Johns, 369), is directly in point on a similar general provision in the Medical Act of 1813 (2 R. L., 219–222, § 12). But if it were necessary for the doctor to renew his license, *non constat* that it was not done.

"Such a defect would reach but to the latter part of his practice in the defendant's family. He had been retained long before 1830, and continued to practise generally after that time. The presumption is, therefore, that he had obtained the proper diploma under the Revised Statutes, in other words, renewed his license." . . . .

The doctor recovered his fees.

In 1841 a case was decided in the Supreme Court (Finch *v.* Gridley's Executor, 25 Wend., 469), which held that "a physician may maintain an action for medical attendance rendered by him, although he has neglected to deposit a copy of his license in the clerk's office of the county of which he is a resident." In this case the plaintiff claimed $230 for his attendance as a physician upon the testator.

On the hearing he produced a paper purporting to be a certificate granted by the president of the Medical Society of Columbia County, certifying that he, the physician, had been regularly admitted a member of such society. It bore the date of June 6, 1837, and purported to be signed by R. Van Beuren, President. It was proved that R. Van Beuren was addressed as president of the County Medical Society, and that his name appeared in publications as such officer, and that the signature to the certificate was in his handwriting. The plaintiff also produced a diploma, granted by *the Medical Society of the County of Herkimer, at Fairfield*, under the seal of that institution, signed by the president and secretary, bearing date January 14, 1835, conferring upon the plaintiff the privilege of practising physic and surgery in this State, etc.

The defendants proved that the plaintiff had *not deposited* a copy of his license in the clerk's office of the county of Columbia. After hearing the evidence of the parties in relation to the medical attendance of the plaintiff, the referees, before whom the case was heard, made a report in favor of the plaintiff for $116, which the defendants moved to set aside.

The counsel for the defendants insisted "that the evidence was insufficient to show that the plaintiff was duly licensed to practise physic, and *that, at all events, having neglected to deposit a copy of his license in the clerk's office of the county in which he resided, he was not entitled to recover.* The act concerning the practice of physic, in section nineteen, declares that until such license is so deposited the physician *shall be liable to all the penalties* provided by law, in the same manner as if he had no license. It cannot be that a party can maintain an action for services rendered for another, when such services, by the imposition of a penalty, are manifestly deemed by the legislature illegal."

By the Court, Nelson, Ch. J.—"The first section of the Act regulating the practice of physic and surgery (1 R. S., 448) provides that the president of every county medical society shall give notice to every physician and surgeon, not already admitted into such society within the county, requiring him within sixty days to apply for and receive a certificate of admission as a member. Section second declares a forfeiture of the license of the physician or surgeon not complying with such notice. The sixteenth section forbids the practice of physic or surgery by any person, unless a license or diploma for that purpose has been obtained from one of the incorporated medical societies in this State, or the degree of Doctor of Medicine from the regents of the University, etc. The nineteenth section requires the physician to deposit a copy of his license with the clerk of the county where he resides; and in default thereof, he is declared liable to all the penalties provided by law, in the same manner as if he had no license. The twenty-fourth section disables every person not authorized by law to practise physic or surgery, from collecting any fee by suit, and the twenty-fifth section subjects him to a penalty of $25, for each offence.

There was sufficient proof of the granting of the certificate of membership of the County Medical Society of Columbia, which was, at least, *prima facie* evidence of authority to practise. The first section of the act requires all physicians and surgeons within the county to apply for such certificate; and it is but reasonable to presume it would not have been granted unless the party was deemed properly qualified to practise. The second section confirms this view; for the physician forfeits his license, and subjects himself to all the disabilities of the statute, if he fails to procure such admission. I am also inclined to think the evidence which was given competent to prove the *diploma* from the college at Fairfield. . . . Then, was the *deposit of a copy of the license* in the county clerk's office an essential prerequisite? I think not. The nineteenth section makes the physician 'liable to all *penalties* provided by law,' in case of default. It is insisted that penalties here include the disability to sue for fees under the twenty-fourth section, as well as the forfeiture of the $25 under the twenty-fifth section. The provision, being penal, should be strictly construed and limited to its technical common law

meaning. That is fully accorded by restraining it to the forfeiture in the latter section. This view is confirmed by a reference to the language of the seventeenth section, which requires the physician coming from abroad, in terms, to file a copy of his diploma before he is entitled to practise. It is fair to presume similar language would have been used in respect to our own diplomas had the legislature intended to apply a like rule. They, doubtless, regarded the penalty of $25 for each offence sufficient punishment for the neglect."

Motion to set aside referees' report denied.

An appeal case was heard at the October term of the Superior Court of the City of New York, 1829, which is reported under the name of Elisha Smith *v.* William Tracy (2 Hall's R., 465). The head-note is as follows: "The plaintiff brought an action of assumpsit for work and labor bestowed by him as a physician, surgeon, and apothecary, on the defendant's wife, and for the medicines found and applied by him in the course of his attendance as such physician. It appeared at the trial that the plaintiff had no license authorizing him to practise, but was employed by the defendant to attend upon his wife, and in the course of such attendance furnished a quantity of medicines, for the preparing of which he had obtained a *patent;* and he sought in this action to recover a compensation for his services as a physician, and also for his medicines. Held, that he was not entitled to recover any part of his claim, not even for the patent medicines furnished in the course of his attendance."

It appeared in evidence at the trial, that the plaintiff had *no license* authorizing him to practise as a physician, but he was employed by the defendant to attend his wife, and in the course of such attendance furnished a quantity of medicines, for the preparing of which he had obtained a patent; and he sought in this action to recover a compensation for his services as a physician, and also for his medicines. The recovery was resisted on the ground that the statute disabled the plaintiff from maintaining the action. The plaintiff, it appeared, was a practitioner in "*botanic medicines*," and he attended the defendant's wife thrice every two days, from October, 1828, to April thereafter. Her complaint was a cancer, and the bill of particulars showed a list of medicines amounting to $75, and visits to the amount of $150. No cure was effected, a regular surgeon having been called in before "the work was completed."

At the trial, the plaintiff was nonsuited upon his own evidence.

The opinion of the court was given by Oakley, J. (after a statement of the facts of the case). "By the twelfth section of the Act Regulating the Practice of Physic and Surgery (2 R. L., 222), it was provided that if any person shall practise physic or surgery without a license, 'he shall forever thereafter be disqualified from collecting any debt or debts incurred by such practice, in any court of the State.' By the new revised code, which was in force at the time the plaintiff rendered the services in question (1 R.S., 455, § 22), it is enacted that every person '*not authorized by law*, who for any fee or reward shall practise physic or surgery within the State, shall be incapable of recovering by suit *any debt arising from such practice.*' The provisions of both acts, in this respect, are similar in effect, and undoubtedly must receive the same construction.

"In the case of Timmerman *v.* Morrison (14 J. R., 370), the Supreme Court held that, by the true construction of the former act, no person practising without a license could recover for *services rendered or medicines furnished* as a physician or surgeon.

"In Allcott *v.* Barber (1 Wend., 526), the action was for *medicines furnished.* The plaintiff in that case, being an unlicensed physician, was employed to attend the defendant's daughter, *and, in the course of such attendance, furnished a quantity of medicine.* The Court of Common Pleas, in which the action was tried, directed the jury that the plaintiff had a right to recover for the value of the medicine furnished; and the Supreme Court held that direction to be erroneous. The Chief Justice says that '*where the same person officiates as physician and apothecary*, he comes within the decision of *Timmerman v. Morrison;*' and he says that, 'if it were otherwise, the country would be filled with quacks and pretenders, *peddling their nostrums*, and deceiving and destroying the ignorant and the credulous—the very mischief which the statute is intended to prevent.'

"I cannot distinguish the case now before us from Allcott *v.* Barber. The plaintiff acted in the joint capacity of physician and apothecary. The medicines charged by him were used and applied in the course of his attendance and prescriptions as a physician. The case comes entirely within the principle of that decided by the Supreme Court, and must be controlled by it.

"It is contended by the plaintiff, that the patent in evidence in the case gives him the right to sell the medicines in question, notwithstanding the provisions of the State law; and his general right to sell his medicines as an apothecary is not questioned in this case. The patent confers no additional right on him, but precludes others from selling or using them. The State law, by the construction given to it by the Supreme Court, prohibits him from '*peddling his nostrums*' in the character of a physician, and inducing people to buy and use them in consequence of their reliance on his pretended skill. Such practices the law of the State has declared to be dangerous to the public health, and if the patent in question had authorized him, in express terms, to vend his medicines in the manner in which he has done it in this case, I should have no hesitation in holding that the patent would be inoperative against the provisions of the law. It is not necessary, however, to enter further into this view of the case.

"The plaintiff also contends that the knowledge of the defendant that the plaintiff was an unlicensed physician is a feature in this case, which distinguishes it from those decided by the Supreme Court. I cannot so consider it. That knowledge, no doubt, existed in the case of Allcott *v.* Barber, and exists also in the great majority of cases in which unlicensed physicians are employed. The mischief intended to be prevented by the statute is injury to the 'ignorant and credulous,' and the protection of the statute to that class of people would be in a great measure defeated if a circumstance of such common occurrence were permitted to take the case out of its operation. The motion to set aside the nonsuit must be denied."*

These references and quotations embrace all the adjudicated cases by the higher courts of the state

* This "practitioner" professed to cure "most diseases incident to humanity," among which were enumerated gout, gravel, asthma, syphilis, stone, dropsy, ulcers, salt rheum, *affections of the nerves, palpitation of the heart*, St. Anthony's fire, tetters, scald heads, *consumptions*, and *all* diseases arising from *impurity of the blood.* One of his recipes for a "*tincture*" in the above complaints was as follows: "Take one gallon of cider, half a pound of horse-reddish (sic) root, a quarter of a pound of white-oak bark, and two ounces of oxyd of iron. Let the mixture stand six days, stirring it twice every twelve hours, *and it will be fit for use.*"—REPORTER.

down to the passage of the Act of 1844, entitled "An Act in relation to the Practice of Physic and Surgery," passed May 6, 1844 (Laws 1844, chap. 275, p. 406).

The following is the text of the act in full, as well as of the Act of April 7, 1830, which it expressly repeals:

SECTION 1.—The twenty-second section of chapter fourteen, title seven, part first of the Revised Statutes, and all laws of this State which prohibit any person from recovering, by suit or action, any debt or demand arising from the practice of physic or surgery, or a compensation for services rendered in attending the sick, or in prescribing for the sick, are hereby repealed

SECTION 2.—The act entitled "An Act concerning the Practice of Physic and Surgery in this State," passed April 7, 1830, is hereby repealed.

(This act was as follows: Chap. 126, Laws 1830; "An Act concerning the Practice of Physic and Surgery.

"SECTION 1.—All that part of section twenty-second of title seventh of chapter fourteenth of the first part of the Revised Statutes, after the words 'such practice,' at the end of the third line, be and the same is hereby repealed.

"SECTION 2.—Every person not authorized by law who shall practise physic or surgery within this State, shall, for each offence of which he may be duly convicted, forfeit and pay a sum not exceeding twenty-five dollars, to be recovered, with costs of suit, before any justice of the peace of the county where such penalty shall be incurred, by any person who will prosecute for the same, 'and the same shall be paid over for the benefit of the poor. But the provisions of this section shall not be deemed and taken to extend to or debar any person from using or applying, for the benefit of any sick person, any roots, barks, or herbs, the growth or produce of the United States.'")

SECTION 3.—No person shall be liable to any criminal prosecution, or to indictment, for practising physic and surgery without license, except in cases of malpractice, or gross ignorance, or immoral conduct in such practice.

SECTION 4.—All and every person, not being a licensed physician, who shall practise or attempt to practise physic or surgery, or who shall prescribe for or administer medicines or specifics to or for the sick, shall be liable for damages, in cases of malpractice, as if such person ware duly licensed to practise physic or surgery.

SECTION 5.—Any person, not being a licensed physician, who shall practise or profess to practise physic or surgery, or shall prescribe medicines or specifics for the sick, and shall, in any court having cognizance thereof, be convicted of gross ignorance, malpractice, or immoral conduct, shall be deemed guilty of a misdemeanor, and liable to a fine of not less than fifty dollars, nor not exceeding one thousand dollars, or imprisonment in the county jail not less than one month, nor exceeding twelve months, or both, in the discretion of the court.

We have given the whole text of this act, known in the books and decisions as the Act of 1844, to gratify a legitimate curiosity to read the law, which, it has been held, did away with all distinctions in this State between the different schools of medicine, and which is commented upon with vigor in two or three opinions which we shall refer to and quote from.

The first reported case is that entitled Bailey *v.* Mugg (4 Denio's R., 60, January, 1847), in which we give all of the opinion of the Supreme Court which has a bearing upon the question under consideration.

By the Court, Beardsley, J.—"This action was brought in 1845 to recover a compensation for medical attendance and medicines furnished and administered by the plaintiff, as a *botanic* physician, in 1840. The *plaintiff was not licensed to practise medicine*, and the only question is whether such an action could be sustained.

(To be continued.)

## Progress of Medical Science.

TRANCE AND TRANCOIDAL STATES IN THE LOWER ANIMALS.—These peculiar phenomena form the basis of an article by Dr. George M. Beard in the *Journal of Comparative Medicine and Surgery*, April, 1881, and the following are his summaries: Trance is a concentration of the nervous activity in some one direction. It is a state of degrees and gradations all the way from full trance, in which there is absolute suspension of the nervous activity in every direction except one, and a corresponding concentration of activity in an exceedingly narrow and limited phase, as in apparent death and long-continued rigidity, and so-called trance-coma, to the mildest and most transient dazing and bewilderment. Trance, as it exists in lower animals, whether quadrupeds, fish, or insects, or in forms of life in which the nervous system exists, is the same condition precisely as trance in human beings, and is explained by the same theory. Through the whole range of phenomena, it is obedient to the same natural law, which is now no longer mysterious. It is explained as satisfactorily as any of the great laws of nature, certainly as any in the domain of biology. The state of trance has indeed in many aspects, already obtained the predictable stage—the last and best test of the organization of any science, where we can tell beforehand what will happen with certainty in many instances.

The only difference between the milder trancoidal states, so often observed in animals and in men, as in cases of intellectual absent-mindedness and the temporary loss of presence of mind, and the full trance, in which the animal or person is absolutely unconscious for minutes or hours, or days, or sometimes years is a difference of degree rather than of kind, and there can be no scientific study of the subject which fails to recognize this fact. These trancoidal states bear much the same relation to full trance that epileptiform and neurasthenic or neurasthenoidal states, or insanoidal states bear to epilepsy or neurasthenia or insanity.

The methods or processes of inducing trance and trancoidal states in the lower animals and in man are infinite, and there is no one of these methods that are best known which can be said to have any special or pre-eminent virtue over the other, except of convenience and degree. The philosophy in all these processes and manœuvres is to so alter the nervous equilibrium as to produce concentration of the nervous forces in some one direction, with corresponding cessation of nervous activity in other directions, and this can be accomplished by acting on the nerves of general sensation or of special sense, with profound excitation of emotion of fear and induction of physical helplessness, as when a horse is cast on

his side so that it is impossible for him to rise, or a hen is securely tied by the feet, while at the same time the emotions of fear are energetically acted upon, and the nerves of sensation are effected by manipulation, or by fixing the look on the eyes. The simple excitation of the emotion of fear is itself, without any physical accessories, the most powerful of any single exciting cause, in animals or in men. When, for example, a horse is in a stable that has caught fire, he is often unable to move; he is then in a condition of trance, and the paralysis of motion which subjects him to the danger of burning to death rather than escape, is one of the symptoms of the trance thus induced. The temporary paralysis of a horse unable to cross a track or move in any direction when a train of cars is approaching, illustrates the same principle. Human beings when surprised, in the same way, as when an alarm of fire takes place in a crowded building, are likewise entranced, and exhibit the same phenomena. Of the special senses, that of sight is decidedly the best to act upon, in order to induce the trance or trancoidal state. All the other senses may be similarly utilized; as the hearing, when the animal listens to music, or to any monotonous sound, or the falling of water, even the ticking of a clock or watch; the sense of smell, as when some powerful and agreeable odor is brought near to the nostrils. All these experiments apply with equal force to the higher as well as to the lower animals.

THE STORM-WATER QUESTION IN RELATION TO SEWERAGE.—The bearing of this question at the present time upon the sanitary condition of our towns and villages, is now meeting general consideration.

In discussing this subject in the *Sanitary Journal*, March 1, 1881, Col. George E. Waring suggests that, after proper provisions have been made for the drainage of the subsoil, our only care with regard to the rainfall should be to provide means by which it shall escape, without material inconvenience to traffic; that in so doing it shall wash the street gutters, and without causing material damage to property. There is nothing in the nature of the rain-water that makes its temporary sojourn on the surface of the ground injurious to health, therefore there is no reason why it may not be allowed to wash the face of the streets, and course along the gutters, provided only its volume is not so great as to interrupt or seriously to interfere with traffic, as already mentioned. Consequently, as the roadside gutters are in full view, and may easily be kept clean and in repair, there is no reason why the rain-water may not flow through them for, at least, so far as they are ample to provide for its escape. Sooner or later, however, in large cities, the water from copious rains will exceed its bounds and submerge the streets, or possibly the sidewalks, hence, a possible danger to the pavement, that cellars will be filled, and travel interrupted. Then, but not until then, it will become necessary to carry the flow below the surface of the street, and lead it to a safe point of outlet. Storm-water, therefore, may properly be kept on the surface of the streets as long as possible, and when its accumulations must necessarily be carried beneath the surface, they should be only at such depths as are requisite to get them out of the way, and to prevent their filling with ice during the slight flow in cold weather. In Camden Town, and Kentish Town, the new sewerage system is deluging the poor inhabitants. Taken from the surface of the streets where it would have done good sanitary service in flushing the gutters, the rain-water has been delivered into sewers, which carry it with great velocity, causing an accumulation at lower levels where the pumps have not capacity to remove it. The evil has therefore merely been transferred to the lower-lying areas, where, but for the sewers, the water would, at least, have arrived so gradually as to have done a minimal harm. Mr. Waring designates the present manner of disposing of storm-water in several towns, by removing it from the surface, where it is needed, to the sewers, where it creates a nuisance, as a "relic of barbarism," and its continuance indicates an "overriding of reason by tradition."

A NEW AND CONVERTIBLE SURGICAL APPARATUS.—Dr. John Cousins has introduced to the notice of the profession a very simple and convenient apparatus, which can be used for a great number of surgical purposes by making slight alterations in its component parts. A special feature consists in the application of lever action over the bed without weight or contact with the bed itself. By a mechanical contrivance of great simplicity, a lever is sustained immovably in any position, and by this means many of the ordinary surgical instruments, including the fracture-swing, the bed-cradle, the extension-pulley, the bath-hoop, the splint-elevator, and bed-rest, are reduced to the form of one efficient, portable, and economical apparatus. The following is a short description of some of the principal applications (*Lancet*, April 23, 1881): The fracture-swing is supported by two uprights, which are secured to the sides of the bedstead. It can be used with any kind of ordinary splint, and it supports the limb at any required height; at the same time, it can be used to swing both legs, if necessary, without any addition to the apparatus. Besides, it occupies no space in bed, permits a free circulation of air under the bedclothes, and does not require to be removed in dressing the limb. The apparatus is also convertible, by a very simple arrangement of wooden rods, into an elevator of the entire bedclothes, which will be found of great service in the application of hot-air and vapor baths. Special iron-wire splints, fitted with shifting-bars and movable hand- and foot-pieces, form a part of the apparatus, and, by means of a sliding metal rest, they can be adjusted on the cross-bar at any convenient height. This apparatus is claimed to have advantages over any now in use.

PROGRESSIVE PAINFUL INFLAMMATION OF ARTERIES.—At a meeting of the Clinical Society of London, Mr. Morgan presented a patient aged forty six years who had contracted syphilis at eighteen. Five years previously he began to suffer from pain in the left armpit, then in the bend of elbow. Afterward he had a similar attack, for which there seemed no evident cause. One year ago the difficulty recurred in the right groin; it was deep-seated and was painful when the part was pressed. The area of pain was confined to two or three inches in the course of the femoral artery, and to one or two inches on either side of it. This pain gradually travelled down along the course of the artery to the popliteal space, being traceable throughout, but most severe where it merged into the popliteal. In course of time the pain extended into the leg, and here some limited œdema corresponded to the area of its presence. Similar symptoms originated in the right axilla, and passed gradually down in the course of the brachial artery into the forearm, and here again a limited œdema occurred. He was treated with iodide of

potassium, alkalies, and biniodide of mercury, at various times, and in varying quantities, but without material effect upon the disease. Subsequently, the right carotid artery was affected in a similar way. The symptoms pointed evidently to disease of an artery, probably inflammation of the fibrous coat, since the pain passed from the centre to the periphery, was in the various arteries, and was made intense directly the finger perceived the pulsation of the artery beneath it. There was no history of gout. At no time was there any indication of plugging or impeded blood-flow in the affected arteries. Unfortunately, no sphygmographic tracings were taken. —*Lancet*, April 23, 1881.

On the Treatment of Uterine Myomata.—Lawson Tait's experience in the treatment of uterine myomata, has convinced him that ergot has not a decided influence in restraining the hemorrhage. He has tried it in all its forms, combined with bromide of potassium, various astringent acids, and other drugs recommended by various authors, but without in a single case realizing permanent benefit from it. The hemorrhage from this class of tumors, he says, does not cease in a large number of cases at the ordinary climacteric period, as is generally supposed; but, on the contrary, the presence of the tumor seems to be the cause of a prolongation of the menstrual activity for a period as great as ten years after the ordinary climacteric age has been reached, and not only is this hemorrhage frequently fatal, but it is productive of a condition of ill-health and chronic anæmia from which the patients do not recover, even after the menopause has been reached. For such cases, therefore, surgical interference is demanded, and it depends entirely upon the results of empirical experience what shall be proven to be the best. Concerning the operation of enucleation, he believes it to be a most unscientific and altogether unjustifiable operation, the risks are so great, and the results, even of a successful operation, so disappointing, that, in his opinion, it is not a profitable proceeding. He will never undertake it again. The objection to the removal of these tumors by abdominal section is, that in a very large number of cases the tumors cannot be removed, being so related to the uterine structure as to afford no pedicle. In two such cases he attempted enucleation from the abdomen, but had to desist, and both patients died. In cases where there was such a pedicle as enabled him to remove the tumor and deal with the pedicle, by clamp or ligature, he has operated six times, with only two recoveries, and these were cases where the wire clamp was used. The recoveries were protracted, occasioning profound anxiety; and though in the end satisfactory, presented nothing of the easy, uninterrupted, and rapid course which was the case in all his ovariotomies. Of the cases where he dealt with the pedicle by ligature—three in number—not one recovered. They all died of continuous oozing from the stump. He therefore concludes that hysterotomy is not advisable. Ovariotomy he considers the best method of procedure, having had success that was most gratifying. Since his first operation (August, 1872) he has performed ovariotomy ten times for menorrhagia due to uterine myoma, with one death. In order to illustrate how useless other treatments are in dealing with these cases, he recites the history of the following case in the *Annals of Anatomy and Surgery*, June, 1881. The lady in question, when forty-seven years of age, began to lose most profusely at her periods, and rapidly became extremely anæmic. The loss was ascribed to natural changes and nothing active was done. One year afterward a tumor was detected, and after putting her through all kinds of treatment, injecting ergotin hypodermically, and strong astringents into the uterus, with but temporary benefit, the cervix was divided, which for the time being seemed to abate the loss to some extent; but subsequently, at the age of fifty-two, ovariotomy was resorted to, from which operation the patient made a good recovery. In seven other cases the results have been as good, so far as time has allowed. In the ninth, death occurred, seven months after the operation, from cancer. The hemorrhage was completely arrested for three months. Besides these cases, he has operated in two others for menorrhagia with perfect success.

The method of the performance of the operation he describes as being very simple. The smallest possible incision is made, often barely two inches, and search is then made with the left fore and middle fingers for one ovary after the other. He does not remove one until he is satisfied that he can remove both. The mesovarium is then transfixed with a hooked needle and a loop of silk is carried through. It is then tied by his special knot, termed the "Staffordshire Knot," and the ovaries are cut off with scissors or knife and the wound is then closed. In one case he had to make a ten-inch incision and pull a very large tumor right out of the abdomen before he could find the ovaries, which were down behind it. He had a great deal of difficulty in forcing the tumor back into the abdomen, but the patient made an uninterrupted recovery, and the tumor is now, two months since the operation, less than it was at the time by at least one-third, and the hemorrhage has not recurred.

Suppurative Pyeophlebitis in a Child.—At a meeting of the Paris Anatomical Society, Chauffard reported the case a child, twelve and a half years of age, that had died in a children's hospital. The disease had begun seven weeks before admission with symptoms of fever, vomiting, diarrhœa, and abdominal tenderness. Shortly after cessation of the febrile movement, intense epigastric pain set in, ascites, and œdema of the legs; rapid emaciation also developed, and the child died in extreme cachexia. Albumen had not been detected in the urine. At the autopsy, the abdominal cavity was found filled with about three quarts of a yellow, serous fluid. The peritoneum, although hyperæmic, showed no adhesions. There was some swelling and pigmentation of Peyer's patches, and the spleen was enlarged. The trunk of the vena porta was filled with thick pus, but showed no thrombosis. In the thickened intima wrinkles were numerous, and fibrinous deposits likewise. Both mesenteric veins were similarly involved, whereas the splenic vein contained only coagulated blood.

It was ascertained that the disease of the portal vein extended into the substance of the liver up to the finest ramifications of that vessel. Minute perivascular abscesses were also discovered. The interlobular vessels were found transformed into channels consisting of embryonal corpuscles, and the adjoining liver-cells were pushed asunder by proliferation of these bodies. This, together with the pressure resulting from the distention of the intralobular veins, had caused atrophic changes in the hepatic parenchyma. The cause of the malady was not discovered.—*Le Progrès M'd.: Jahrb. für Kinderheilk.*, December 23, 1880.

## ALUMNI ASSOCIATIONS.

It is an evidence of progress in the right direction that alumni associations are being organized all over the country, and that a becoming interest is being manifested in the increase of their membership and the extension of their usefulness. While we should be encouraged at this state of things, there are many offsets against the real utility of these organizations which it is well at times to consider. As social gatherings they may be considered eminently successful. The annual dinner generally brings together a goodly company, and with the unexceptionable menu is invariably associated the usual intellectual treat of brilliant post-prandial oratory. On such occasions a great deal is said complimentary to "our alma mater," her past history and her glorious future, and all present unite in believing that they are fortunate in being the children of such a mother. Beyond this little is usually done save the election of officers for the ensuing year, and the provisions for reimbursing the treasury.

It is true that some steps have been taken toward improving the condition of the various colleges, but that such have fallen far short of what was at first anticipated as possible must be readily admitted. In a few instances attempts have been made to endow certain chairs, and although these have been partially successful, it only affords a proof of how much more must be done in the same direction before the associations can exert their proper influences for good upon their respective alma mater.

It seems quite evident that one of the reasons why more progress is not made in the direction indicated, is a want of agreement between the faculties of the college and the members of the association as to what is really required to advance the interests of all concerned. The colleges are willing to receive all that is given to them in the shape of suggestions and endowments, but do not appear to show a disposition to concede anything in return. Although a right of representation on the part of the alumni is allowed in the governing element of some of the schools, it is practically of no account in carrying out any given plan for improvement, or even in influencing any action in such a direction. The representation is allowed merely by courtesy, and is limited to one or at most two members of the association. These change from year to year by election, and give no opportunity for any continuous advocacy for reform, which is so necessary to the desired end.

As a further hindrance to the good purposes of alumni associations must be mentioned the fact that, in a few instances at least, these organizations are more or less under the control of the faculties. In other words, the associations are becoming subjected to college cliques, are being managed accordingly, and are consequently losing their representative character.

One reason, perhaps, for this is the want of interest among the large majority of the alumni in the government of their association, and in the too ready acceptance of a foregone conclusion that none but men more or less directly connected with the college are eligible for office. Although the interests of the alumni and of the faculty must not be antagonistic if any real improvement is to be made in our medical colleges, there should be at least a sufficient balance of power and influence on the side of the former to give it a becoming show. There is no doubt that the alumni associations have a great deal of power if they will arise to their opportunities and appreciate the full force of professional opinion in favor of the reforms they have attempted to effect. And we have a full and abiding faith that the time is fast approaching when the proper influence will be exerted on the one hand and appreciated on the other. In the mean time let the members who are active in their organizations take courage and remove any dead weights that may be hindering the slow but sure progress of the necessary reforms in our present system of medical education.

---

### LEUCOCYTHÆMIA IN MAN AND THE DOMESTIC ANIMALS.

M. Nocard, Professor in the Veterinary School at Alfort, has made some investigations into leucocythæmia as it occurs in the lower animals and in man. His studies, presented in the form of a monograph of eighty pages, cover the whole subject of the disease, and contain much that is of interest.

Leucocythæmia in the domestic animals was observed soon after the disease was discovered in man. It has a prevalence here which would hardly be suspected. The histories of forty-three cases are presented by M. Nocard. Twenty-two of these occurred in dogs, nine in horses, and a smaller number in the cow, the pig, and the cat. It has been found in other animals, such as the guinea-pig.

We cannot review the whole subject as presented by the author, but will refer to the points which are unique, or which have a special pathological interest.

The most frequent form of the disease in the lower animals, as in man, is the spleno-lymphatic, and next to that the splenic. There are some cases in which only the bronchial glands and lungs are involved. Cases illustrating the purely intestinal form are also given, but there are none of the medullary type, and only three cases are known in which the bone medulla was at all affected.

The changes in the blood have some peculiar features. In the domestic animals the normal number of white and red corpuscles, and the ratio between them is greater than it is in man. The average number of red blood globules in the adult horse and dog is 7,500,000 per cubic centimetre. In leucocythæmia this number is reduced to 5,000,000 (the normal number in man) or to 2,000,000. The ratio between the white and red is never smaller than 1 to 12, and often is 1 to 80 or 40. The normal ratio in the domestic animals being 1 to 800 or 1 to 1,000.

Certain successive measurements made by M. Nocard, of the blood of a dog with intestinal leucocythæmia, show a progressive disease in the red corpuscles corresponding with the increase in the white.

The enumerations took place about two weeks apart and gave the following results:

*First enumeration.*—Red blood-corpuscles, 3,425,000 per cubic centimetre; white blood-corpuscles, 12.780: ratio, 1 to 400.

*Second enumeration.*—Red blood-corpuscles, 3,160,000; white blood-corpuscles, 36,800: ratio, 1 to 86.

*Third enumeration.*—Red blood-corpuscles, 2,350,000; white blood-corpuscles, 76,200: ratio, 1 to 30.

This may be interpreted that the red globules, while being used up as usual, or faster than usual, do not receive a fresh supply by transformations of the white. There has been no better theory than that which Virchow originally advanced regarding the essential factor in producing the disproportion of red and white corpuscles in leucocythæmia. This is, that the white corpuscles early in their development are *normally* turned into red, as they pass through the spleen (and medulla of bones), and to some extent while in the blood itself.

In leucocythæmia part of these corpuscles lose the power of undergoing this change and become veritable pus-cells. The observations of Nocard, so far as they go, tend to confirm the theory that there is no increased manufacture of white corpuscles in leucocythæmia, but rather an inability on the part of these cells to go through their normal metamorphoses. The total number of blood-cells is greatly diminished. The symptoms and the severity of the disease are much more due to the lack of the red corpuscles, and consequently of hæmoglobin, than to the excess of the white cells.

It is the opinion of M. Nocard, as well as of other observers, that lymphadenia or Hodgkin's disease, in which there is hyperplasia of lymphoid tissue with profound anæmia, but no relative increase of white cells, is identical with leucocythæmia. This view is by no means universally accepted. And there is certainly some difficulty in fitting it to the view, that the essence of the trouble in leucocythæmia lies in the inability of the white cells to undergo their normal transformations. We can only assume that in Hodgkin's disease the hæmatopoetic organs produce absolutely fewer cells; in leucocythæmia degraded cells are largely thrown out. In the one the deficiency is largely quantitative, in the other qualitative.

But, whatever the theory, there are many clinical facts in favor of the view advocated by M. Nocard. He relates the history of a horse which showed marked development of lymphatic tissue with all the symptoms of leucocythæmia. The blood, however, at first, though very poor in corpuscles, held them in normal proportions (6,675,900 to 9,640).

It was a typical case of Hodgkin's disease. Three weeks later there was a profound leucocythæmia, the ratio of corpuscles being 4,682,500 to 12,250. Other similar cases are given.

As a result of his studies on the lower animals, therefore, M. Nocard defines leucocythæmia as a general diathetic affection characterized by the production, more or less rapid, in all the organs of lymphadenoid tissue. The disproportionate increase of white blood-cells (leucocytosis) is only an accessory fact, an epiphenomenon, not constant, and of which the presence or absence does not modify the symptoms or progress of the affection. It only appears, in the domestic animals at least, at an advanced stage of the disease, and comes on slowly; it may even disappear temporarily or definitely, while the lymphoid growth persists or increases.

The white corpuscles in leucocythæmia, as observed by M. Nocaro, are of two varieties. The one is the ordinary large nucleated white corpuscle; the other consists of apparently a free nucleus, colorless, staining deeply with carmine, without amœboid movement, and of a diameter about equal to that of the red blood-corpuscles. In splenic leucocythæmia the smaller corpuscles (globulins) are very few in number. In intestinal and ganglionic leucocythæmia they predominate over the other forms.

The blood coagulates very slowly, though the fibrin factors are increased. In the horse the clot forms in three characteristic layers, the lower being red from the red globules, the upper being yellow with fibrin, and the middle white with leucocytes. Chemically the blood, as in man, is very deficient in hæmoglobin, and contains a large amount of abnormal crystallizable matters.

In the symptomatology of the disease there are two points of interest brought out. In intestinal and ganglionic leucocythæmia there predominates among the white cells the peculiarly modified form which we have just described. Whether the predominance of these cells, when the spleen is not involved, can have any bearing upon the mode of origin of the blood corpuscles is a question for the physiologist. Another peculiar symptom noted was a polyuria, which only occurred in pulmonary leucocythæmia—that is, when the bronchial glands and lungs were largely involved. The urine in the horse in such cases is increased to two or three times its normal amount (twelve quarts), and the hippuric acid is replaced by urea.

An analogy has sometimes been traced between Hodgkin's disease and acute tuberculosis, the course of the two diseases and the gross appearances as regards the lungs being somewhat alike. Experiments have been tried in order to see whether the new lymphoid tissue or its juices were inoculable. But inoculations, subcutaneous and venous injections, and feeding, all failed to produce any results.

The progress and final termination of leucocythæmia in lower animals do not differ from that in man. Regarding treatment, experiments in the direction of extirpating the spleen and lymphatic glands have, as might be expected, proved unsuccessful. The disease is deep-seated, and fatal to every animal it touches.

### A STATE MEDICAL SOCIETY INDEED.

One of the duties of the medical journalist is to pass, in more or less critical review, the work of the profession in its individual or corporate capacity.

We have accordingly published an account of the meeting of the Iowa State Medical Society, and we shall be pardoned now for making some criticisms upon its work.

As the result of two days' work, the society heard an annual address, a number of reports, and six papers. The delegates also had their photographs taken in group, they took a ride upon the river, and attended eleven elegant receptions. Four or five members who were to have read papers were away, or not prepared. The essays read, with two or three exceptions, were absurdly valueless. The president's address, we are glad to say, was a bright spot in the proceedings. It was an appropriate and scholarly effort, and showed that Iowa certainly has cultured physicians who keep abreast of the thought of the day. The report on insanity and the papers on empyema and color-blindness also deserve notice.

But, on the whole, this meeting was the most singularly barren one that we have experienced the distress of reading about for some time. Iowa is a great State; it has many physicians whom the local press hospitably designate as its "Life-preservers." But they seem to be utterly ignorant of such a thing as medical science, or of the object of medical organizations. We beg, therefore, to remind our esteemed brethren of the State in question that they who study only the art of medicine have no claim to be called members of a learned profession. It is largely to encourage scientific knowledge that societies are organized. But our Iowa "Life-preservers" seem to have united mainly for the propagation of rides on the river, and for the perpetuation of elegant receptions, where the medical mind shall relax its tension and grow giddy beneath the smiles of Iowa's daughters.

In these days of prolific writing no one should inflict a paper on a medical society unless it reviews progress or contains something presumably new and valuable. We trust that the Medical Society of the State of Iowa may remember this. It surely can do something worthy of medical science and of the State. It surely has not done so yet.

## Reviews and Notices of Books.

A Treatise on the Diseases of the Nervous System. By William A. Hammond, M.D. With one hundred and twelve illustrations. Seventh edition. Rewritten, enlarged, and improved. New York: D. Appleton & Co. 1881.

This, the seventh edition of Dr. Hammond's work, has been considerably remodelled. The chapters on insanity are left out; there are additions to the subjects of cerebral congestion, locomotor ataxia, progressive facial atrophy, chorea, epilepsy, and neuralgia. There are new chapters on the symptomatology of cerebral and cerebellar lesions, on the diseases of the sympathetic nervous system, myxœdema, and syphilis of the brain and cord. The author states that he is indebted for much of the new matter to Dr. Labadie-Lagrave, the editor and translator of the French edition of the work.

Dr. Hammond's work has now been before the profession for many years, and its characteristics are very generally known. The present edition has a good many valuable additions, but has lost nothing of its previous individuality as a medical work. Dr. Hammond has the qualities of a successful author. He has extensive knowledge, though it is more varied than profound. His practical experience is large, his convictions are positive, and he can set them forth clearly and attractively. It is not surprising that his book has been a very popular one. And the present edition is, as modestly stated on the title-page, "improved."

No one should read this work, however, without bearing in mind its undoubted weaknesses. The author, with all his acuteness and wide observation, is not, we venture to think, an accomplished physiologist or a thorough pathologist, and he is, therefore, often a superficial reasoner upon points involving these sciences. One might also find some fault with his anatomical knowledge, for he continues to announce (p. 643) that "the *sacral* portion of the cord presented no abnormal appearance to the naked eye." But this particular spinal cord came from Delhi, where, perhaps, they grow longer.

A large part of the pathology of the present work is a compilation; what is original is, we think, bad. For example, Dr. Hammond has enlarged his experience and his remarks on the subject of cerebral congestion. He gives, with much minuteness, the symptoms of the prodromal period and of the four different forms of this supposed condition. The chapter is a most misleading one. We have not space to go into a critical analysis of it. We would say, however, that the idea that cerebral congestion is the cause of various definite trains of morbid symptoms is to a large extent hypothetical.

The theory is not supported by post-mortem evidence; there is no unity upon the question of symptoms among clinicians. Many of the symptoms now widely recognized as due to nutritive disturbances, or neurasthenia, are here, without good reason, assigned to congestion. In the recent Croonian lectures Dr. Moxon has shown very clearly how slight a basis there is for assigning congestion as the primary cause of so many cerebral disturbances. The description of the value of the ophthalmoscope and otoscope in diagnosing this same condition gives a very wrong impression as to the value of these instruments. It may be laid down as certain that one cannot diagnose congestion of the brain by examining the retina. A retinal and cerebral congestion may go together and they may not. At best an ophthalmoscopic examination can have only a weakly confirmatory character. The same, so far as investigations have gone at present, may be said of the examination of the tympanum.

We might criticise, with equal reason, the author's pathological theories regarding the spinal cord: its anæmic tracts and its perceptive and other psychical powers. It might be said also that a more philosophical writer would have referred to some of the peculiarities in the morbid phenomena of the nervous system of Americans. It is certainly time that physicians, and especially neurologists, recognize the fact that nations and races have their idiosyncrasies as well as individuals. But we may perhaps be bringing into too great prominence points which after all do not greatly impair the value of the book. It is a treatise very creditable to American medicine, and widely and justly appreciated abroad, as well as here. One has to read it with a little reserve, but after all it is perhaps the most instructive as it is the most interesting work on the subject of nervous diseases in the English language.

THE DIAGNOSIS OF DISEASES OF THE SPINAL CORD: An Address Delivered to the Medical Society of Wolverhampton, October 9, 1879. By W. R. GOWERS, M.D. With Additions and Illustrations. Second Edition. Pp. 84. Philadelphia: Presley Blakiston. 1881.

WE CAN warmly commend this little book. It gives in small compass the main points regarding the anatomy and physiology of the cord, with the indications for diagnosing the seat and character of the various lesions. In his expositions the author rides no hobbies, but presents the established facts with clearness, and discusses mooted questions briefly and judiciously. There are some excellent diagrams of the cord. The book is a year old, and lacks in one or two points on that account.

DR. J. SUYDAM KNOX has been made Adjunct Professor of Diseases of Children in Rush Medical College, Chicago.

# Reports of Societies.

## AMERICAN NEUROLOGICAL ASSOCIATION.

*Seventh Annual Meeting, held in New York, June* 15, 16, *and* 17, 1881.

WEDNESDAY, JUNE 15TH—FIRST DAY, AFTERNOON SESSION.

THE association met in the hall of the New York Academy of Medicine, and was called to order at 2.30 P.M. by the President, DR. ROBERTS BARTHOLOW, of Philadelphia.

NOMINATIONS FOR MEMBERSHIP.

The following were nominated for membership:

Drs. A. B. Clevenger and H. Gradle, of Chicago; Dr. Burt G. Wilder, of Cornell University; and Drs. C. K. Mills and Wharton Sinkler, of Philadelphia.

The PRESIDENT appointed the following

COMMITTEE ON NOMINATIONS:

Drs. J. S. Jewell, of Chicago; Isaac Ott, of Pennsylvania; R. W. Amidon, William J. Morton, and A .D. Rockwell, of New York.

COMMUNICATIONS TO THE ASSOCIATION.

DR. J. C. SHAW offered the following resolution, which was adopted:

*Resolved*, That no case be presented to the association unless it forms the basis of a written communication.

RESIGNATION.

The resignation of Dr. T. B. M. Cross, of New York, was read and referred to the Council. (Subsequently accepted.)

AMENDMENT TO THE CONSTITUTION.

An amendment providing for the election of honorary and associated members, proposed by the Secretary, DR. E. C. SEGUIN, was adopted.

The first paper was read by DR. J. C. SHAW, of Brooklyn, and was entitled

THE TENDON REFLEX IN GENERAL PARALYSIS OF THE INSANE.

In 1879, Dr. Shaw read before the association a paper on the "Tendon Reflex in the Insane," in which he stated, as the result of his examinations in *ten* cases of general paralysis of the insane, that tendon reflex was absent in *three* cases; that when it was absent, the diagnosis of sclerosis of the posterior columns of the spinal cord was justifiable, and he also, at that time, ventured the opinion that light cortical sclerosis would not abolish the tendon reflex. His more recent observations had confirmed the opinions then expressed. He had had under observation 82 cases of general paralysis of the insane, 71 males and 11 females, and had had the opportunity to examine the spinal cord microscopically in 18 cases. Dr. Shaw's conclusions were that, whenever tendon reflex is abolished, sclerosis of the posterior columns exists; when the tendon reflex is very slight, the posterior columns are the seat of disease, and later it will be entirely abolished; where the reflex is normal, autopsy shows no lesion in the spinal cord, and when it is exaggerated there is secondary degeneration symmetrically of the lateral columns, or

diffuse myelitis, which involves more or less the white matter, but the lateral columns chiefly. To abolish tendon reflex, the sclerosis must be quite extensive.

DR. J. S. JEWELL, of Chicago, asked with reference to the mechanism of the cases in which there was abolition of tendon reflex with sclerosis of the posterior columns.

DR. SHAW replied that the disease interfered with the sensory tract so as to interrupt the sensory power.

DR. A. D. ROCKWELL, of New York, had no doubt that, as a rule, where there was much disease of the posterior columns, tendon reflex was abolished, but in fourteen cases of posterior spinal sclerosis which he had observed there were two in which tendon reflex existed. In two cases he had been unable to get it, although the patients were apparently healthy, so far as the spinal cord was concerned.

DR. SHAW had seen cases in which tendon reflex was absent without other evidence of disease of the spinal cord, but he regarded them as exceptional. He thought that Westphal believed that in such cases disease of the posterior columns exists.

DR. BARTHOLOW, of Philadelphia, asked if it was true tendon reflex in such cases.

DR. SHAW thought that it had been so regarded.

DR. SEGUIN, of New York, referred to a paper written by Dr. Landon C. Gray, in which several cases of absence of tendon reflex in apparently healthy persons were reported.

DR. JEWELL remarked that when he found tendon reflex absent, he always suspected disease of the posterior columns of the spinal cord, and the mechanism he regarded as exceedingly simple, viz. : that the diseased portion was directly across the ingoing impulse.

If, however, there were no other signs of disturbance in the sensory tract of the cord, he regarded it as one of a class of cases in which tendon reflex was absent, because persons differed very greatly with reference to tendon reflex, as they did with reference to the presence or absence or degree which existed with regard to the other reflexes.

### CENTRAL NERVOUS SYSTEMS OF REPTILES

was the title of a paper sent by DR. J. J. MASON, of Newport, and read by the Secretary. It was discussed by Dr. E. C. Spitzka, of New York.

DR. ISAAC OTT then read a paper

### ON THE ACTION OF AN IRRITANT.

The writer concluded that certain irritants produce a variety of phenomena referable to the nervous system, while others do not; that those phenomena were not due to circulatory changes, but to excitation of the central nervous system; that they produce partial palsy of the motor nerves of the opposite side; that they inhibit the cardiac and respiratory centres; that they lower the temperature and dilate the pupil.

The paper was discussed by Drs. E. C. Spitzka, J. S. Jewell, E. C. Seguin, and W. J. Morton.

### PECULIAR EFFECT OF BROMIDE OF POTASSIUM IN INSANE EPILEPTICS

was the title of a paper sent by DR. H. M. BANNISTER, of Chicago, and read by the Secretary.

The effect referred to by Dr. Bannister was the development of maniacal furor while the insane epileptic was taking bromide of potassium. A detailed history of one case was given in which the epileptic convulsions were arrested, but soon afterward maniacal furor developed, which subsided upon withdrawing the remedy, and returned with its renewal. Two other similar cases were cited.

DR. SPITZKA said that attention had been directed to this peculiar effect by a German alienist. He had also observed cases of the kind reported by Dr. Bannister, and believed that it would result in more than twenty-five per cent. of the inmates of our public institutions.

DR. JEWELL remarked that, while the peculiar action of the bromide mentioned had not been unknown, it was important, whether the proportion of cases was as large as suggested by Dr. Spitzka, or was small. The fact should be recognized. He thought it probable that quite a number of epileptic insane, placed in asylums and kept upon the classical bromide treatment, were there as insane persons for that very reason. In all cases of epileptic insanity this possible effect produced by bromide of potassium should be constantly and distinctly borne in mind; that is, one of the results of the bromide treatment of epileptic insanity, whether directly or indirectly was not determined, was maniacal furor, which rendered the person dangerous and liable to confinement and restraint.

DR. J. C. SHAW had seen this peculiar effect more frequently in dispensary practice and among children than among the inmates of an asylum. He had seen one or two cases in the asylum of which he has charge, in which it became necessary to discontinue the drug.

DR. SEGUIN had observed this peculiar condition in several cases, but he did not believe that it was due to the bromide. He thought it was due rather to the suspension of the epilepsy. Vander Kolk had observed the same thing while treating epileptics with setons, and by allowing the patients to have fits the mental equilibrium had been restored. Dr. Seguin had observed the phenomenon following the suspension of the *petit* and the *grand mal*, and believed that it was due to the suspension of the epileptic condition rather than to the drug.

DR. WILLIAM A. HAMMOND, of New York, said that, while it was true the sudden suspension of epilepsy would produce mental aberration, he thought it was an infrequent occurrence when the frequency with which epileptic paroxysms were stopped without the development of these symptoms was considered. He had seen many cases in which acute mania had been produced with bromides, and he believed that there was a stage beyond which bromides could not be continued without producing mental aberration. The cumulative properties of the bromides should be studied more carefully than they had been. He had had four patients die while under the extensive use of bromides under his direction. Sometimes the dangerous symptoms could be removed by purgation.

DR. ROCKWELL referred to a case in which, under his direction, the bromides had been continued eighteen months, with the view to carry the patient over, if possible, the point at which the convulsions had heretofore returned, and now, in view of Dr. Bannister's case and others reported, it became a question with him whether or not the remedy should be continued, as the patient was very much depressed, threatened suicide, etc.

DR. HAMMOND said that if he had epilepsy he would take the bromides all his life.

The association then adjourned to meet at 8.30 P.M.

FIRST DAY, EVENING SESSION.

The association was called to order at 8.45 P.M. by the President. The Council recommended for membership Drs. A. B. Clevenger and H. Gradle, of Chicago; Burt G. Wilder, of Cornell University, and C. K. Mills, of Philadelphia. They were elected by an affirmative ballot cast by the Secretary.

REPORT OF THE COMMITTEE ON NOMINATIONS.

The Committee on Nominations reported: *For President*, Dr. William A. Hammond, of New York; *For Vice-President*, Dr. Landon C. Gray, of Brooklyn; *For Secretary and Treasurer*, Dr. E. C. Seguin, of New York; *For Members of the Council*, Drs. J. S. Jewell, of Chicago, and Isaac Ott, of Pennsylvania. These candidates were elected by a ballot cast by the Secretary.

DR. A. D. ROCKWELL then reported, with remarks, a case of

PERIPHERAL PARALYSIS FROM PRESSURE,

which illustrated the fact that complete absence of electro-muscular contractility is not necessarily an unfavorable condition which cannot be removed. The point specially insisted upon was the persistent use of the galvanic current, although response might not be obtained for a long time. In the case reported one month elapsed before the muscles reacted at all, and in a case previously reported it was six weeks before galvanic contractility took place.

DR. W. A. HAMMOND thought all would agree that it was more difficult to restore electro-muscular contractility where the paralysis was due to peripheral injury, than in a case in which it was of central origin.

DR. JEWELL thought that many cases of peripheral paralysis, in which there was evidence of absolute destruction of nerves, should be considered more hopeful than they usually were. He then cited a case in which the left lower extremity of a woman had been utterly useless for eleven months, with paralysis of sensation and motion after delivery with instruments, and by using the interrupted galvanic current, with massage, persistently for nearly a year, she was almost completely cured.

DESTRUCTIVE LESION OF THE LEFT CENTRAL HEMISPHERE

was the title of a paper sent by DR. H. D. SCHMIDT, of New Orleans, and read by the Secretary.

The man received a blow from a club, on the left side of his head, in 1865 or 1866, and was uncon scious for several weeks. There was also paralysis of the extremities of both sides. No scalp-wound was produced. The man recovered and retained all his mental faculties. At the autopsy, a large hole—9½ ctm. horizontal by 5 ctm. vertical—was found in the bony vault, in the left parietal region, closed by a dense membrane. Beneath this was a large, ovoid hemorrhagic cyst. As the result of pressure produced by the cyst, the cerebral hemisphere presented a concave surface, the white substance of the brain had been destroyed, while the gray matter remained in the shape of a shell. The chief interest in the case centered in the extent of the lesions, and the length of time which they had existed without disturbing either the general health or the mental faculties of the patient.

DR. J. S. JEWELL, of Chicago, then read a paper

ON THE EARLY USE OF STRYCHNIA IN MYELITIS,

the special object of which was to call attention to the early and free use of this remedy in acute and subacute affections of the spinal cord, in which its use had apparently been held to be unphysiological and even dangerous. The cases were those in which the accepted treatment had consisted in the use of ergot, massage, counter-irritation, electricity, etc., but in which, while the condition of the patient was daily and steadily growing worse, he had turned to strychnia in small and gradually increased doses, persistently used, and with the result of greatly benefiting the patient. In the persistent use of strychnia, exceeding care to prevent the patient from using the spinal cord (rest in bed perpetually, on the side or face), exceeding care to protect the patient from exposure (temperature of room maintained at 70° F.), so as to avoid a chill, were the important elements in his plan of treatment.

He had no theory to offer, except that the blood-vessels lost their *tonus* very quickly, and the vaso-motor apparatuses became fatigued and exhausted much earlier than was ordinarily supposed.

DR. W. A. HAMMOND asked Dr. Jewell three questions.

*First.*—Did the strychnia produce any tonic spasm?

*Second.*—Were the cases cited uncomplicated ones of disease of the spinal cord?

*Third.*—Might they not have been cases of spinal anæmia?

DR. JEWELL replied, first, that no tonic spasms were produced; second, that they were uncomplicated cases of disease of the spinal cord; and third, that he had not lost sight of the question of spinal anæmia, and had discussed it in the latter part of his paper, which had not been read.

On motion, the further discussion of Dr. Jewell's paper was made the first order for Thursday's session, after which the association adjourned to meet at 2 P.M. on Thursday.

---

THURSDAY, JUNE 16TH—SECOND DAY, AFTERNOON SESSION.

The association was called to order at 2 P.M. by the President.

The Council recommended for membership Dr. Wharton Sinkler, of Philadelphia, and he was duly elected.

Letters of regret at being unable to attend the present meeting had been received from Dr. John Van Bibber, of Baltimore, and Dr. J. J. Mason, of Newport, and the latter extended a cordial invitation to the association to hold its next annual meeting in that city.

THE EARLY AND FREE USE OF STRYCHNIA IN SUBACUTE MYELITIS AND ALLIED FORMS OF DISEASE OF THE SPINAL CORD.

The discussion of Dr. Jewell's paper on the above subject being next in order,

DR. E. C. SPITZKA remarked, that he would not dare to use the remedy in the early stages of inflammatory diseases of the cord. His experimental researches, however, had led him to the conclusion that the drug might perhaps be used in the early stages with benefit, if irritative symptoms were not present.

DR. HAMMOND asked Dr. Spitzka if he did not discover, after giving excessive doses of strychnine to an animal, rupture of blood-vessels in the substance of the spinal cord.

DR. SPITZKA said he always did when death was quickly produced.

DR. HAMMOND asked if that fact did not indicate

congestion of the spinal cord as an effect of the strychnia.

Dr. Spitzka said that he had always attributed the hemorrhages to respiratory spasm and death by asphyxia.

Dr. Hammond asked if, in a case of congestion of the spinal cord, the susceptibility of the cord to the influence of strychnia was not increased. He believed that Dr. Jewell's cases were anæmia, rather than congestion of the cord, and one strong point of evidence in favor of that position was the fact that in none of them were any of the physiological effects of strychnia produced, which must have occurred had the condition been that of congestion. In anæmia of the cord, strychnia could be given in very large quantities without producing its physiological effect. He admired Dr. Jewell's judgment, respected in the highest degree his opinion, accepted without reserve his observations, but doubted the correctness of his diagnosis in the cases reported.

Dr. Jewell did not wish in the least degree to escape the criticism offered by such a matured judgment and experience as Dr. Hammond's, but, on the contrary, enjoyed them; for he was fully aware of the difficulties in making a differential diagnosis between spinal anæmia and spinal congestion, and was willing to meet them. In his judgment it was possible, in ninety-nine out of a hundred cases, to determine with tolerable accuracy whether we had to deal with decided spinal anæmia or decided spinal congestion —difficult as the cases were to distinguish the one from the other.

*First.*—That acute and passive congestions of other organs of the body existed was well known and not disputed.

*Second.*—That such congestions existed in the central nervous system (cranial) no one doubted.

By passive congestion he meant that which might be regarded as almost purely vaso-motor in its origin, and he spoke with special reference to arteries and capillaries. The quantity of blood in those vessels might be increased, in consequence of disorders of their walls, either muscular or vaso-motor. The condition was that of loss of *tonus* in the muscular coat of the blood-vessels, and the result, passive congestion.

*Third.*—Spinal anæmia was made better by increased atmospheric pressure, whether it be obtained at the sea-level or in an air-tight chamber.

*Fourth.*—Cases of passive congestion of the spinal cord improved when sent to higher altitudes.

*Fifth.*—Spinal anæmia was made better by exposure to cold (cool, bracing climate), and increased in severity in warm climates.

*Sixth.*—Spinal passive congestion, on the contrary, improved under the influence of warmth; hence, the patients did better in a warm than in a cold climate, and were beneficially affected by the local application of heat, the use of the Turkish bath, etc.

*Seventh.*—There was a diminution in all the reflexes in passive congestion of the spinal cord.

By anæmia he meant contraction of a blood-vessel in consequence of a stimulus which reached it. That implied some excitation of the vaso-motor supply, which could be traced usually to some irritation, whether in the pelvic, the gastric, or an intermediate zone.

Dr. Jewell continued his remarks at some length and presented other points in the differential diagnosis.

Dr. Hammond thought it curious that Dr. Jewell saw cases of congestion in such numbers, and anæmia so frequently, when exactly the opposite would be true if Dr. Jewell's argument concerning the effect of atmospheric pressure had any sure foundation. In other words, he regarded it as a fine illustration of transcendental philosophy to conclude that because a patient improved under such and such circumstances and was worse under opposite ones, he therefore must have congestion or anæmia, and it was begging the question completely.

Dr. E. C. Seguin was opposed to the doctrine of the existence of hyperæmia and anæmia, and looked upon the terms spinal hyperæmia and spinal anæmia as merely expressions for hypothetical views. He knew of no post-mortem or experimental evidence which supported the doctrines. All that had been heretofore adduced were observed and therapeutical phenomena put together in the right way to prove the existence of these two conditions. With respect to the spinal cord, researches had not shown any basis for the opinion that hyperæmia was the first step in myelitis. It was not even an important factor. The changes which took place were tissue-changes from first to last. With reference to the use of strychnia, however, he was inclined to agree with Dr. Jewell, but would suggest that the term "subacute myelitis" be changed to *subacute diffuse myelitis*. He had administered the remedy in moderate doses in diffuse myelitis, following diphtheria, etc., with the best of results, apparently due to the strychnia, and he was prepared to continue its use in acute diffuse myelitis.

The discussion was continued by Drs. Landon C. Gray and E. C. Spitzka and closed by Dr. Jewell, who said that he did not at all regard congestion as the first condition in inflammation, but simply as a clinical factor. Long before the congestion appeared tissue-changes existed, and the hyperæmia was entirely secondary. Besides, he did not share in that scientific sceptical nihilism presented by Dr. Seguin, which accepted nothing except what could be seen or smelled, or was susceptible of mechanical demonstration. It was all well in its legitimate field, but there was a *logical inference* which should be respected in all successful efforts to obtain the truth. That he had succeeded in obscuring Dr. Hammond's comprehension was more than he expected at the outset, but he promised to elaborate and set his views forth so clearly in the subsequent publication of the paper that even his learned opponent would be forced to acknowledge their value.

### STATIC INDUCED ELECTRICAL CURRENT.

Dr. W. J. Morton read a paper on the above subject, which will be published in a subsequent number of the Record. (See Medical Record, vol. xix., p. 368.)

Dr. W. R. Birdsall, of New York, thought it should not be called an "induced" current.

Dr. Rockwell believed that, absolutely, static electricity was of value, but relatively it had not the value claimed for it. The question was further discussed by Drs. Gray, Seguin, Gradle, and Morton.

### THE HYPOTHETICAL AUDITORY TRACT

was the title of a paper read by Dr. Græme Hammond, of New York. (See Medical Record, vol. xix., pp. 309 and 429.) It was discussed by Dr. Spitzka, and also by Dr. E. C. Seguin, who reported an autopsy confirmatory of Dr. Hammond's observations (see Dr. Ball's case, Archives of Medicine, April, 1881).

Dr. George M. Beard then read a paper

ON THE MEDICAL USE OF STATIC ELECTRICITY,

in which he stated that it ought to possess some advantage over galvanism and faradism, but such advantage had not been proved, because there were no facts from which the comparison could be made. He thought that the term "induced" used by Dr. Morton was admissible, although strictly and technically incorrect, and he suggested the term "statical current of electricity" as one which would avoid confusion and stand the test of criticism.

Drs. Rockwell, R. W. Amidon, of New York, Birdsall, and Morton participated in the discussion, the drift of which was not favorable to static electricity. First, galvanism or faradism, and then franklinism.

HOW TO USE THE BROMIDES

was the title of a paper read by Dr. Geo. M. Beard, in which he gave the following propositions:

*First.*—The object, generally, in using the bromides was to produce a definite effect—bromization in a greater or less degree.

In a certain sense it was a disease artificially produced. Severe effects were not required. Mild effects of the remedy were all that were needed in most cases.

*Second.*—To induce bromization it was usually advantageous to give immense doses. He often prescribed as high as a dram or more. Doses of fifteen or twenty grains might be taken for some time without giving rise to symptoms of any kind. In some cases one hundred grains taken in one or two tumblers of water was all that would be required to break up an attack of hysteria, headache, or prevent seasickness.

*Third.*—They should be given in immense doses, only for a short time, save in epilepsy and epileptoid conditions. The cumulative effect must be recognized and constantly borne in mind. Sometimes a single large dose was sufficient to produce bromization, and that might occur within twenty minutes.

*Fourth.*—Bromides, if used long and frequently upon any one patient, should be given in alternation or combination with tonics of some kind. Bromides one week and tonics the next, was a good rule.

One of the best remedies against bromization was powdered citrate of caffein, in from three to five grain doses.

*Fifth.*—It was of advantage to use a number of bromides in combination.

While administering the bromides the patient should be kept under observation continuously.

The paper was discussed by Drs. W. A. Hammond, L. C. Gray, E. C. Seguin, and J. S. Jewell.

Dr. Hammond preferred the bromide of sodium, if any of the salts were to be employed, but of late he had been using pure bromine, and had thus avoided the acne and the ulcerative manifestations of the bromide salts. His formula was

℞. Bromine..... 3 j.
Aquæ..... ℥ viij.

M. S.—Teaspoonful well diluted with water.

Dr. Jewell had used pure bromine with favorable results in cases in which the alkaline bases could not be tolerated, and Dr. Seguin had reached the conclusion that the efficient agent was the bromine, and not the potassium.

The association then adjourned, to meet on Friday at 2 P.M.

Friday, June 17th—Third Day, Afternoon Session.

The association was called to order at 2.30 P.M. by the President.

The Secretary announced the reception of letters from Drs. Eads and Putnam, of Boston, regretting their inability to be present.

NERVE-STRETCHING IN LOCOMOTOR ATAXY

was the title of a paper read by Dr. W. A. Hammond, of New York.

The sciatic nerve was stretched. His conclusions were that there was ground for hope with reference to the operation. A moderate extension, not to exceed an inch, was all that was necessary. The best place to reach the nerve was just where it came from under the biceps muscle. Too much stretching was bad. A *résumé* of nine cases was given, seven by other observers and two of his own.

Dr. Jewell mentioned two cases reported recently by Bernhardt, in which the success had been marked, but not complete.

Dr. G. Hammond referred to a case in which the operation was followed by an aggravation of all the symptoms.

The discussion was continued by Drs. Rockwell, Morton, Spitzka, Amidon, Seguin, and Birdsall, and a doubt concerning the propriety of the operation seemed to be the result; also a doubt whether the good results which had been obtained were due to the nerve-stretching or to the operation itself.

Dr. H. Gradle, of Chicago, then read a carefully prepared paper on

CILIARY SPASM OF CENTRAL ORIGIN.

It was discussed by Drs. Spitzka, Seguin, and Jewell.

Dr. W. R. Birdsall, of New York, exhibited

A NEW FOOT-DYNANOMETER,

and Dr. G. Hammond, of New York, described a dynanometer which determined the number of pounds registered.

Dr. F. T. Miles, of Baltimore, reported a case of

DIFFUSE MYELITIS.

A man, thirty-three years of age, was seized with symptoms of congestive malarial fever, was treated with quinine, apparently recovered, but had a relapse. Soon afterward he began to suffer from weakness, pain, and numbness in his lower extremities, and finally had complete paralysis of the lower, and extreme paresis of the upper extremities, and most complete paralysis of the face upon both sides. There was no tendon reflex. There was marked delay in the transmission of sensation, and finally there was decided hyperæsthesia. There was mechanical response to striking the muscles, no response to faradism, but degenerative reaction to galvanism. There was neither bladder nor bowel trouble. Respiration was not affected, nor deglutition, and the patient could cough and protrude his tongue. He lived in a malarial region. It was probable that at one time he was affected with syphilis. He recovered completely under the use of iodide of potassium, electricity, etc.

Dr. Jewell referred to a case with an almost identical clinical history, except the suspicion of syphilis, but the man became hopelessly ruined by contracture. The discussion was continued by Drs. Seguin and W. A. Hammond, and at its close the association adjourned to meet at 8.30 P.M.

THIRD DAY, EVENING SESSION.

The association was called to order at 8.45 P.M., by the PRESIDENT.

The Council recommended for

HONORARY MEMBERS,

J. M. Charcot, Paris; J. Hughlings Jackson, London; W. Erb, Leipsig; C. Westphal, Berlin; Theodore Meynert, Vienna. Unanimously elected.

The Council further recommended for

ASSOCIATED MEMBERS,

Thomas Stretch Dowse, W. R. Gowers, David Ferrier, H. Charlson Bastian, and J. Russell Reynolds, of London, Eng.; Moritz Bernhardt, of Berlin; Camillo Golgi, of Reggio, Italy; and Dr. Obersteimer, of Vienna.

DR. L. C. GRAY called up his proposed

AMENDMENT TO THE CONSTITUTION,

proposing that the officers of the Association be nominated by the Society on the first day of the annual meeting, instead of by a committee on nominations.

Adopted.

TRANSFERRED MEMBERS.

Dr. N. B. Emerson, of Honolulu, and Dr. Lombard, of London, Eng., were transferred from active to associated membership.

DR. F. T. MILES, of Baltimore, presented a specimen of

TUMOR OF THE PONS,

and DR. CHARLES K. MILLS, of Philadelphia, read a paper on the same subject, with the addition,

CONJUGATE DEVIATION OF THE EYES WITH ROTATION OF THE HEAD,

which was discussed by Drs. W. A. Hammond and Spitzka.

DR. F. P. KINNICUTT, of New York, reported a case of

CHOREA MAJOR.

The case was interesting chiefly on account of the high temperature, 103° F. and upward, thought to depend upon the ceaseless and violent muscular contractions, the improvement under hydrate of chloral, and the tolerance of the drug which the patient, a girl aged fourteen, exhibited, taking from seventy to one hundred grains daily.

DRS. MILLS and JEWELL doubted the causal relation claimed between the muscular contraction and the elevation of temperature.

RESISTANCE OF TABETIC PATIENTS TO ACONITIA

was the title of a paper read by DR. E. C. SEGUIN, of New York. He had observed in nine cases, two by Dr. Birdsall and seven of his own, that the patients took large doses of aconitia, as high as six one-hundredths of a grain of Duquesnel's preparation, without producing any of the physiological effects of the drug.

He suggested that it might be a new symptom of posterior spinal sclerosis.

The paper was discussed by Drs. Jewell, W. A. Hammond, Spitzka, and Birdsall.

DR. SEGUIN then read a paper on

POST-DIPHTHERITIC PARALYSIS.

Diphtheria followed a slough caused by a carbolic-acid injection into a pile. The patient first noticed weakness on the 20th of December, 1880, the ataxia had passed away on the 7th of February, 1881, and had been succeeded by paralysis, and in the first week of April following the patient had nearly recovered.

DR. MILLS referred to a case in which the paresis disappeared and the ataxia remained, but recovery took place.

DR. SEGUIN regarded his case as one of infectious myelitis.

The place for holding the next annual meeting was referred to the Council with power.

The association then adjourned.

## CONNECTICUT STATE MEDICAL SOCIETY.

[Special Report for THE MEDICAL RECORD.]

THE nineteenth annual convention of this venerable society was held at the Common Council Chamber, City Hall, Hartford, Wednesday and Thursday, May 25th and 26th. The first day's session was devoted to business, and was organized promptly at three o'clock. In the absence of DR. G. S. PLATT, the President, DR. WILLIAM DEMING, the Vice-President, took the chair, and, in accordance with the usual custom, addressed the Fellows on such subjects as appeared worthy of their consideration or action. The continued growth and prosperity of the society was mentioned, as evidenced by its increase in numbers, a healthier condition of the treasury, and prompter payment of dues by members; also by an increased interest in the conventions of the society, and a better attendance. Of those whose duty it was to be here on this day, but four were absent, two of these in Europe. The value and importance of the work of the State Board of Health was considered, and that institution and its general aims and purposes warmly commended. The status of medical education was considered and a four years' course of study recommended, also a better preparatory training. The laws regulating the sale of poisons and the pharmacy act in general was considered and, on the whole, approved. The law concerning itinerant practitioners was pronounced to be a step in the right direction, and would, it was hoped, pave the way for a general law regulating the practice of medicine. The progress of State medicine was also noted. Twenty-six States now had Boards of Health; five, since the last annual meeting of this society, had organized such boards; and several others were considering the subject in their legislatures.

The usual routine business was then transacted, after which the following reports of special committees were received: On Medical Experts, by DR. G. W. RUSSELL, of Hartford. This was a thorough and carefully studied *résumé* of the whole subject. The evils of the present system were clearly and graphically pointed out. At first it seemed that a remedy was easily to be found in the plan of having the judge select one or more medical experts, or having them selected by the court, or some similar plan. The objection that there is no power belonging to either judge or court to summon experts, could be met by a change in the statute law conferring such power; but an insuperable objection to any radical change in the present system lies in the inherent right of the accused to confront the witnesses against him, so that even if the court or judges should summon an expert or a body of experts, and

they should render their opinion, if adverse to the accused he would still have the right to summon his own expert or experts to contravene the testimony against him; nor is there any power that can take that right from the accused.

A skilful lawyer can generally make the mercenary testimony of a biased expert evident to the jury, and thus render it harmless, but it has the effect to depreciate all expert testimony at the same time. The only hope for the future lies in elevating the character and attainments of the medical profession itself, so that it shall be difficult to find amongst its members such professional witnesses as now, to the disgrace of the profession, stand ready to sell their opinion to the highest bidder.

The report of the Committee on the Sale of Poisons, by DR. RUFUS BAKER, of Middletown, recommended that the list of poisons, the sale of which was to be recorded, should be much enlarged, and a second class formed also, whose sale should be restricted. The report on vital statistics did not advocate any additional legislation. There was considerable discussion on certain abuses in publishing the names of patients or physicians in local papers when publishing registration reports. While no further legislation was advocated, the subject was referred to the Secretary of the State Board of Health, requesting him to take such action as might be necessary.

A Majority and Minority Report were presented on the subject of a Lunacy Commission. On the majority report DR. SHAW defended the present method of treating the insane, while admitting the necessity of progress in some departments, and commending lunacy commissioners especially for the larger States. The minority report by DR. CLEAVELAND, of Middletown, was devoted to an attack on the present system, a portrayal of its evils, and in general occupying the same ground as that taken by Dr. Wm. A. Hammond and his followers; he also condemned the plan of a lunacy commission, except a national organization. Owing to the lateness of the hour, debate on these papers was postponed, and they go over to the next convention as unfinished business.

The report of the TREASURER was next read and referred to the auditing committee, who reported that they had examined it and found it correct. It shows a balance of nearly four hundred dollars in the treasury, and an increased honesty among the members in paying their just dues to the society. These are small to each individual, but negligence in payment or delay causes great annoyance to the officers of the society.

The Nominating Committee made report, and officers were elected as follows: *President*, Dr. William Deming, Litchfield; *Vice-President*, Dr. William G. Brownson, New Canaan; *Secretary*, Dr. G. W. Chamberlain, Hartford; *Treasurer*, Dr. F. D. Edgerton, Middletown; *Committee on Matters of Professional Interest in the State*, Dr. W. A. M. Wainwright, Hartford; Dr. L. S. Wilcox, Hartford; Dr. G. F. Sims, Bridgeport.

The Committee to nominate Professors to the Medical Department of Yale, reported that they had held a session during the year and recommended the following as Professors in that College: Dr. M. F. Prudden and Dr. F. E. Beckwith.

The Committee on Honorary Members and Degrees reported the name of Pliny Earle, of Northampton, Mass., for honorary membership. By rule this lies over one year.

After the transaction of the usual routine of business the convention adjourned. In the evening a reception was given by the well-known gynecologist, DR. M. D. MASON, which was largely attended and proved a very enjoyable affair.

---

THURSDAY'S SESSION.

The convention met at half-past nine, the PRESIDENT-ELECT in the chair. The SECRETARY read the report for the preceding year. The same general features marked this year that had been the characteristics of the last few years: a steady increase in numbers, interest in the society, and a more healthy state of the treasury. In three of the counties, Hartford, Middlesex, and Tolland, it has now become the rule to pay clear every year all dues; in three others the deficit was very small; while in the other two, New Haven and Fairfield, there were signs of marked improvement over former habits. The society now numbers four hundred and thirty, a net gain of ten over last year. There were thirty new members, seven deaths, and thirteen removals. Ten of the new members were graduates of Yale Medical School, nine of the College of Physicians and Surgeons, and the rest divided among several schools, one or two of each.

The report of the Committee on Matters of Professional Interest discussed the recent prevalence of small-pox, and the contagiousness of consumption, which was the subject for report from the county societies. It was the general opinion that consumption was contagious by long contact, *e. g.*, sleeping with a consumptive; the influence of a wet location as a predisposing cause was noticed by some; that resulting from occupation by many, *e. g.*, stone-cutters, polishers, grinders, etc. The history of epidemic diseases during the year, in the report of the State Board of Health was especially commended. The report was followed by considerable debate.

Delegates from other societies and reports of delegates to other societies were then received, also members of other societies present. Dr. Robert Dixon, a delegate from the Maine Society; Dr. T. W. Perry, a delegate from the Rhode Island Society, presented the greetings of their societies. A telegram was also received from the New Jersey Medical Society, then in session at Long Branch, to which the secretary was directed to respond. Dr. E. C. Seguin, of New York, an honorary member of this Society; Dr. Pliny Earle, of Northampton, Mass.; Dr. Paul Mundé, of New York; and Dr. A. R. Smart, of Michigan, were present as guests of the society.

DR. E. C. SEGUIN, at the invitation of the President of the Society, then read an essay on "The Importance of the Early Recognition of Epilepsy," illustrated with clinical notes. It was a clear and exhaustive discussion of the insidious approach of this deceptive malady, treating of both forms of epilepsy proper, and also of petit mal. Any abstract would fail to do justice; it must be read as a whole to be appreciated. It is a valuable contribution to medical literature from the pen of a master.

DR. S. B. ST. JOHN followed with an able essay on "Sympathetic Ophthalmia," at the close of which he exhibited a magnet for the removal of particles of steel or iron from the eye. At the end was a prolongation to follow the course of the particle, if it had penetrated deeply. The power of this small magnet, as shown in upholding many times its own weight, was remarkable. The essay was very interesting and instructive.

DR. FLUSCHNER, of New Haven, then read an essay

on "Non-pharmacological Therapeutics," in which he discussed many remedial measures of generally recognized value, and others not so well known, all of which were not officinal. The water-cure, massage, and electricity received attention among other agencies.

"The Influence of Temperature upon Disease" was very ably discussed by DR. C. B. NEWTON, of Stafford Springs, and the "Treatment of the Third Stage of Abortion," by DR. J. H. GRANNESS, of Saybrook.

DR. M. D. MASON read a carefully prepared paper on "Lacerations of the Cervix," giving the history, indications, and counter-indications for treatment, illustrating his statements by the details of fifteen clinical cases.

The essay was discussed by DR. MUNDÉ, of New York, who illustrated his remarks by plates in chromo-lithography, prepared for his essay on the subject lately published. He defended the necessity of the operation, and said while chronic peritonitis was a counter-indication for an operation, yet in one case an operation had been necessary for a cure. He also described fully the reflex neuralgia of Emmett, which had thrown discredit upon the operation. The agency of lacerations in producing retroflexion, with its resulting evils, was also discussed.

Essays were expected from Drs. Woodruff and Cressy, but they were unavoidably absent, the one on account of a death in his family, and the other on account of the serious illness of his brother.

DR. WILLIAM C. BURKE, Jr., of South Norwalk, read an interesting paper on "Laceration of the Perineum," and other voluntary papers were read by title, and referred to the Committee on Publication.

The Society then adjourned for the annual dinner at the United States Hotel, which was enjoyed by all, as such social occasions are by physicians fully as much as by any other class of men.

## TWENTY-NINTH ANNUAL SESSION OF THE IOWA STATE MEDICAL SOCIETY.

*Held at Dubuque, May 26th and 27th.*

(Special Report for THE MEDICAL RECORD.)

THE meeting opened at 10 A.M., with about seventy delegates present, DR. S. B. CHARE, of Osage, President, in the chair. An address of welcome was delivered by DR. BELDEN and responded to by DR. WILLIAMSON, on behalf of the Society. Dr. Williamson took occasion to refer to Dubuque as one of the oldest cities in the State, and the first to organize churches, courts of justice, and newspapers.

Various reports were then read, and committees appointed.

At the afternoon session DR. S. B. CHASE, the President, delivered the annual address. He spoke of the contributions to science that were now more than ever being made by medical men. He referred to a criticism of the RECORD upon the "transactions" of the society at the previous meeting.

The criticism ran:

"This volume has some peculiar features, which lend considerable value to what, on the whole, is rather commonplace. . . . There are eighteen papers, and, as representing the work of the society for two years, they do not make a rich display." "Here is," said the speaker, "a literary trout for which we were not angling. Deeply wounded by it, and smarting under its pungent sting, a fellow-contributor writes me: 'I have not the conscience and courage to say that the volume merits a more favorable opinion; and this is why it hurts.'"

The President then asked if it were not possible for the medical men of the State to do better work, and urged them to attempt it more earnestly.

The orator spoke of the act of the Legislature establishing a State Board of Health as indicating progress. The National Board of Health, he thought, had not fully realized the expectations of its friends, especially considering the amount of money furnished to it. The American Public Health Association was doing commendable work, especially in urging the importance of putting education on a more physiological and rational basis. The question whether pneumonia is not an infectious disease, and sometimes epidemic in character, was touched upon, and its great prevalence in Iowa during the past winter referred to. The importance of comparative pathology, the recent studies in the pollution of soils and drinking-water, winter cholera, the best mode of disposing of the dead, the relations of the druggist and physician, the care of the insane, and the importance of collecting vital statistics were the remaining topics discussed.

At the close of the address a paper on "Color-Blindness," by DR. W. CROUSE, of Waterloo, was read. The paper was largely historical and illustrative. The author quoted Dr. Holmes' verse:

> "Why should we look one common faith to find,
> Where one in every score is color-blind?
> If here on earth they know not red from green,
> Will they see better into things unseen?"

Dr. Crouse had examined five hundred men, using the worsted test, and had found about the usual per cent. of affected persons. He urged the importance of legislation on the subject.

DR. ARCHIBALD, superintendent of an institution for training the feeble-minded, said that about two-thirds of this class were color-blind.

DR. HAZEN and others discussed the subject.

The evening session was postponed in order that the delegates might take a ride on the river.

On the second day one of the first things done was to table a petition from the Woman's Temperance Union, asking that the society protest, by resolution or otherwise, against the use of intoxicating liquors.

The committee on the President's address reported, recommending the appointment of a committee to consider and report at the next meeting of the society upon the expediency of discontinuing the publication of "Transactions" until some plan can be devised to improve their character.

DR. ANGEAR, of Fort Madison, made some remarks on microscopy and microscopic specimens. He said he had not committed his remarks to writing, for want of time, and inasmuch as the subject he was discussing was yet in its infancy, it would be inappropriate to publish a paper on it. He urged the importance of a more extended use of the instrument by medical men.

DR. BENJAMIN MCCLUER read a paper on "Injuries of the Orbital Regions;" DR. STAPLES a paper on "Drainage in Empyema," with cases; DR. WARNE a paper on "The Anti-Tonic Properties of Quinine."

In the afternoon a number of new members were elected.

A report of the work on the State Board of Health was made by its chairman, DR. ROBERTSON.

A paper on "Scarlatina" was read by Miss J. S. Braunworth, M.D.

The following resolution regarding medical education was adopted:

*Resolved*, That this society, desiring an improvement in the standard medical education to correspond with that of surrounding States, for their own protection, and for the good of the general public, request every member to use his influence with the members of the General Assembly who may be chosen at the coming election to secure the legislation necessary to that end.

Dr. Watson, of Dubuque, had prepared a paper on

DISEASES INCIDENT TO MILITARY PRISONS,

but it was so long that he concluded not to read it, so much time having been already spent. He severely scored the society on their indisposition and apparent lack of interest in the papers read belore the society, and said there was but little incentive offered to members to prepare papers.

Dr. Ranney, Superintendent of the Insane Asylum at Mt. Pleasant, read a report upon the condition of the insane of the State, which excited much interest and discussion. It appears that many of the insane are confined in county poor-houses. There were not proper accommodations for more than one-fourth the insane. The Committee on Insanity was continued, and authorized to report at the meeting next year.

The following officers were elected: *President*, T. J. Caldwell, M.D.; *First Vice-President*, D. Scofield, M.D.; *Second Vice-President*, M. H. Waples, M.D.; *Secretary*, J. F. Kennedy, M.D.; *Assistant Secretary*, L. C. Swift; *Treasurer*, G. R. Skinner.

The society then adjourned.

A number of elegant entertainments were given to the society in the evening by the ladies of the city.

## Correspondence.

### THE CONSUMPTION OF QUININE AND THE CINCHONA ALKALOIDS.

To the Editor of The Medical Record.

Dear Sir: Your editorial of the 18th inst. in the Record, headed, "Some Facts about Quinine," contains so many statements at variance with widely known facts, that I feel compelled to furnish a corrected statement, which can be relied upon. It is asserted "that of the four chief alkaloids—quinine, quinidia, cinchonia, and cinchonidia—none are wasted by the manufacturers," etc. "It is undoubtedly the case that in nine cases out of ten, persons who go to a drug-store and ask for quinine do not get it, but get quinidia or cinchonidia, or even cinchonia, in its place."

The total yearly product of quinine manufactured in all the world was carefully computed, in 1880, at about 3,500,000 ounces, or very nearly 220,000 pounds avoirdupois, as is correctly stated in the editorial; and the yield of quinidia, which stands next in repute in medicinal value, is very limited—has been computed at not over 175,000 ounces; while of cinchonidia, ranking next in value in medicine, the yield has been computed at 875,000 ounces. The yield of cinchonia has never been computed, because it is so cheap, but a few cents per ounce, and in small demand that it hardly pays to separate, and is apt to lay about as waste in quantity in every manufacturing establishment where the higher alkaloids are separated.

This waste cinchonia waits demand from the East Indies, where from its cheapness it is largely used in the form of a muriate, or more often it passes into chinoidine with other residuums of cinchona which are not crystallizable.

The consumption of cinchona salts in the United States has been computed at—of quinine, 1,000,000 ounces; of quinidia, 50,000 ounces; of cinchonidia, 500,000 ounces, which last is mostly consumed in the North-western States. Very little cinchonidia is sold in the Eastern or Southern States, and particularly in our large cities, where the consumption of quinine is at least twenty ounces to one of cinchonidia. And the statement that no doubt "that in nine cases out of ten, persons who go to a drug-store for quinine do not get it," is a very sweeping one, at variance with both facts and figures, and one that does great injustice to a very respectable profession that is most intimately connected with medicine.

With great respect, I am yours truly,

D. C. Robbins.

[We publish, with pleasure, the opinions of our esteemed correspondent regarding the relative therapeutic value of the articles mentioned in the editorial, notwithstanding they differ from our own; but we are yet unwilling to admit, from any proofs to the contrary, that our "statements are at variance with widely known facts." Neither can we plead guilty of injustice to the druggists referred to in our article, inasmuch as they not only acknowledge that quinine is not given when called for without a prescription, but attempt to justify their conduct in making a substitution.—Ed.]

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 19, 1881, to June 25, 1881.*

Hartsuff, A., Major and Surgeon. To proceed to the Cantonment on the Uncompahgre, Col., and report for duty to Col. Mackenzie, 4th Cavalry, commanding. S. O. 113, Department of the Missouri, June 8, 1881.

Middleton, J. V. D., Major and Surgeon. Having reported in person, is assigned to duty at Fort Hays, Kan., relieving Asst. Surgeon Munn. S. O. 122, Department of the Missouri, June 21, 1881.

Gardner, W. H., Capt. and Asst. Surgeon. Granted leave of absence for four months on surgeon's certificate of disability. S. O. 138, A. G. O., June 18, 1881.

Munn, C. E., Capt. and Asst. Surgeon. When relieved by Surgeon Middleton to proceed to Fort Bayard, New Mexico, and report to the commanding officer for duty. S. O. 122, C. S., Department of the Missouri.

De Witt, C., Capt. and Asst. Surgeon. Granted leave of absence for four months. S. O. 137, A. G. O., June 17, 1881.

Torney, G. H., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month, to take effect when relieved by Asst. Surgeon A. W. Taylor. S. O. 122, Department of the Missouri, June 21, 1881.

Taylor, A. W. First Lieut. and Asst. Surgeon. To proceed from Fort Supply, Ind. Ter., to Fort Lyon, Col., and report to the commanding officer for temporary duty. S. O. 122, C. S., Department of the Missouri.

THE LATE DR. DAVID P. SMITH, OF NEW HAVEN, CONN.—A memorial address was delivered by President Porter, of Yale College, on Monday evening, June 27th, commemorative of the life of Dr. David P. Smith, late Professor of Surgery in the medical department of Yale College.

PRESENTATION TO DR. GEORGE F. SHRADY.—At the meeting of the New York Pathological Society, held June 22, 1881, the presentation of an elegant silver pitcher and salver was made to Dr. Geo. F. Shrady by the members of the society, in consideration of his long services as secretary.

DR. A. JACOBI, in making the presentation in behalf of the society, remarked as follows:

In former times I was not a stranger here. I have been a member of this society these twenty odd years, and have a long time ago enjoyed the greatest honor this society can bestow on any fellow. To-night I am the recipient of another unexpected honor, which, I assure you, as I appreciate it very much indeed will prove an encouragement for resuming in future my former relations to this important and instructive body. I have been distinguished by the committee in charge by permission to address you, Mr. President, in regard to a fellow-member whom we all know, esteem, and honor.

For twenty-two years Dr. George F. Shrady has been the secretary of this society. He has filled that place as only he could have done it. His reports have been careful, full, and correct. They have been a guide to the members, and a source of instruction to medical men in general. They have been read and studied over the United States and abroad, and they have contributed a great deal to fostering the love of pathological anatomy, and its daily increasing study among the profession. That he, while being our secretary for almost a generation, succeeded also in obtaining an extensive literary reputation, that, furthermore, by peculiar characteristics of his own, he endeared himself to a large circle of friends and admirers—all this it is not my domain to-night to allude to. What I am directed to express to Dr. Shrady, in simple and plain words, is the appreciation of his long and valuable services by the members of this society.

We know quite well that he meant to perform his duty only. Neither he nor any sterling man works for thanks or appreciation expressed in any way. The best intellectual and social labors are always performed by those who work from inner necessity only. But when one man works industriously, honestly, and usefully in the service of society, country, or scientific body, it is both natural and becoming, it is good instinct and wise principle on the part of those who derived benefit from his personal efforts to prove themselves worthy of them by word or action.

Thus, Dr. Shrady, I have the great honor of offering you, in the name of the members of this society, this small token of grateful remembrance of your great services. May you live long to enjoy both it and the spirit of appreciating friendship which dictated the gift.

DR. SHRADY, in accepting the beautiful testimonial, was at a loss to thank the society in fitting words. Being at the disadvantage of one who had been taken by surprise, he trusted that he would be excused from any attempt to respond to the eloquent and touching address of his friend Dr. Jacobi. Indeed, with the best of preparation on his part, he doubted if Dr. Jacobi would have given him any opportunity for saying anything more, either of the subject so gracefully treated, or of the individual so pointedly referred to. He could, however, thank the members from his heart. While this was, perhaps, the least he could do, he nevertheless could do no more. The gift had a peculiar value to him, and he trusted that he would ever properly appreciate the sincere motives which had actuated its bestowal.

The pitcher and salver are of elegant design, chaste finish, and bear a suitable inscription with monogram, in Tiffany's best style.

THE STATE BOARD OF HEALTH held a special meeting at the New Capitol on June 23d, and considered the duties imposed on them by recent legislation. There were present: Dr. E. M. Moore, Dr. William M. Smith, Prof. Charles F. Chandler, the Hon. Erastus Brooks, Dr. J. Savage Delavan, Dr. G. S. Hunt, and Dr. Elisha Harris. The act to prevent the adulteration of food and drugs, chapter 407, was discussed at length and the responsibilities of the board in relation thereto were stated in detail. It was resolved to engage competent chemists for the purpose of analyzing samples submitted. Measures were also taken to co-operate with all interested in the sale of pure food and drugs. The alarming prevalence of small-pox and the danger to the State from exposure to this contagion through immigration received a large share of attention, and suitable repressive measures were adopted. Petitions from numerous towns and villages asking the board for the removal of malarial nuisances were submitted, and appropriate action taken.

NEW YORK ACADEMY OF MEDICINE.—At a stated meeting, held June 2, 1881, the librarian acknowledged the receipt of two hundred and sixty-two bound volumes, and several unbound volumes and pamphlets. Of the bound volumes, two hundred and fifty-two, together with a microscope, were presented by the family of the late Dr. Charles M. Allin, as a permanent memorial. A vote of thanks was returned to the donors.

On motion Dr. John G. Adams, Corresponding Secretary, and Dr. H. P. Farnham, Treasurer, were made delegates to the International Medical Congress.

MASSACHUSETTS GENERAL HOSPITAL.—A prize is offered of $400 by the medical staff of the Massachusetts General Hospital for the best essay on chronic Bright's disease.

HEPATIC ABSCESS OPENED WITH TROCHAR AND CANULA.—Dr. W. R. Snook, of Oakwood, O., writes us an account of a case in which a hepatic abscess was successfully treated by the use of the trochar and

canula. The patient, a young man, aged twenty-nine years, had for a year or two suffered from attacks of what had been thought to be chills and fever, or bilious fever. He finally developed a hectic fever with pain and enlargement in the right hypochondrium. His condition rapidly grew worse, until at last, Dr. Day, who had been treating the patient, called in our correspondent in consultation. Dr. Snooks found the liver greatly enlarged and very tender, the patient had fever and night-sweats. The conjunctiva was yellow, the tongue heavily coated, and there was general anasarca. Dr. S. diagnosed the case as one of suppurative hepatitis with abscess not yet fully formed. A few weeks later he was called in again and found the patient much worse. The pulse was 140, tongue brown, breath septic and condition generally very serious. The liver was very much enlarged, especially the left lobe, in which we judge, from Dr. S.'s description, the abscess was located. Not having an aspirator, a trochar and canula were thrust into the liver and forty-three ounces of pus were discharged. The cavity was subsequently washed out with carbolized water, the canula being kept in for a few days until adhesions had formed. The patient at once began to improve and continued to do so, with only one relapse, until finally cured. Dr. Snooks attributes his success largely to his using a uterine syringe, with which he washed out the cavity thoroughly, draining out pus which would have run out of itself.

Historical.—The first regular medical journal ever published was "Les Nouvelles Découvertes sur toutes les parties de la Médecine," and appeared in Paris in 1679.

The first medical library in America was that of the Pennsylvania Hospital, established in 1762.

The first State medical society was that of New Jersey.

The first original medical work published in this country was entitled "Cases and Observations by the Medical Society of New Haven County, in the State of Connecticut, published in New Haven, 1788. —*Maryland Medical Journal.*

Pessary Made of Flesh.—Nussbaum proposes that a pessary be made by folding up the anterior wall of the vagina and securing it with mattress-needles.

The Chicago Faster, Griscom, was alleged to have gone thirty-one days without eating on June 27th. He had, during this time, lost thirty-four and three-quarter pounds. No especial symptoms have developed. His case is exciting but comparatively little attention.

Death of Christ.—The Rev. Professor Haughton recently delivered a sermon on the death of Christ, considered physiologically.

The Medical Law of California, compelling examinations and registration, has been declared unconstitutional. The decision, however, is to be appealed from.

Orchitis and Parotiditis.—Dr. D. H. Webster, of Austin, Mo., writes: "My experience with parotiditis the past winter and spring is confirmatory of that given by Dr. Miller, of Kansas, in the Medical Record, April 30th, and Dr. Bramlette, of Texas, in same journal of June 4th. At least two-thirds of my cases, fifteen or twenty, resulted in metastasis, especially so in the males—only one in a female. Generally the testes, one or both, were much swollen and painful, continuing a regular course of a week to ten days, and, as Dr. Bramlette stated, 'notwithstanding all the precautions, it occurred just as often.' And again during the month of April I was called to see a reported case of measles, and although I had never met with a similar case, my diagnosis was 'German measles,' or 'rubeola,' as given by Dr. Thomas in Vol. II. Ziemssen's 'Cyclopædia.' Three cases occurred in the family of six members, all of whom had had the measles but a few years previous. The infection was brought into the family by a visiting friend from another part of the State. The patients were all adults. One child, who never had the measles, was exposed to this disease, but escaped. The symptoms were well marked: coryza and suffusion of eyes, followed by a profuse eruption, which, in appearance, resembled measles, except the blush was more scarlet. No serious results followed, nor did the disease spread beyond the family."

Dr. M. S. Leslie, of Lexington, Ky., also writes that an epidemic has, within the past few weeks, been under his observation. College students were the sufferers. About one-third of the cases of parotiditis were accompanied by orchitis. There were other cases in which the only local expression of the blood-poison usually producing parotiditis was to be found in the testicle. All recovered readily.

Petroleum in Phthisis.—Dr. M. Milton, of Bradford, Pa., writes: The more we study the statistics of this subject, the more evident does it appear that it is the most fatal of all diseases of human life. It is generally accepted that out of every one thousand deaths, from one hundred and fifty to one hundred and eighty are due to this disease, but this statement gives but a feeble idea of its terrible fatality. It has been ascertained, beyond reasonable doubt, that nearly one-third of all the deaths occurring among adult males, in New York city, are caused by consumption; it has also been ascertained that youth is the harvest-time of consumption, and that liability to it decreases with advancing years is an error—in fact, just the reverse is true. In proportion to the number living, consumption is a more frequent cause of death between sixty and seventy than between twenty and thirty years.

It is not quite certain that there is any marked distinction between the phthisis of the aged and the youthful. Hemorrhage is considered a prodromic symptom of very serious import: it is considered by insurance companies the most valuable sign to the examiner of the consumptive diathesis; it is not considered safe to take a risk for life insurance until ten years have passed after its occurrence. It is stated that primary tuberculosis of the lungs is not only possible, but of very frequent occurrence.

The above are the conclusions deducted from The Mortuary Experience of the Mutual Life Insurance Company of New York. We recognize three stages of the disease—deposition, softening, and excavation. It is questionable whether any material advancement in the treatment has been suggested of late. The contest in those cases is narrowed down to a fight against particular symptoms as they arise, seems to be the ordinary verdict. This is not at all an encouraging outlook.

From statements and observations made, I am inclined to the opinion that in our great staple, crude petroleum oil, we have no mean means of alleviating or arresting the progress of this fatal malady. Dr. Bryan Blacque, of Paris, and Dr. M. Griffith, of Bradford, Pa., report a large percentage of cures by the

various preparations of the crude oil. I find the medicinal oil pleasant and palatable, and I think if the statements of these gentlemen are confirmed by future trials, it will become one of our most valuable medicines.

That consumption seldom originates in the oil country is a well-known fact to all observers.

DEATHS FROM ETHER.—Dr. John B. Roberts, in a paper read before the Philadelphia County Medical Society, relates the histories of persons who died from the effects of ether. From a study of these cases he is inclined to think that the failure of respiration is not always the first sign of danger, but that the heart may begin to fail seriously while respiration continues active. He thinks that the pulse ought to be watched more closely than it usually is, that in some cases the urine ought to be examined as well as the heart and lungs, and that the person who is entrusted with giving the ether should be the most skilful of all the assistants.

Dr. Roberts has collected twenty cases of death from ether that have been reported since January, 1872.

A DEATH FROM VAGINAL INJECTION is reported by Dr. J. M. Dennison. The patient was stooping over a basin and injecting an infusion of oak bark, using an ordinary Davidson syringe. She suddenly experienced violent pains and cramps, evidences of peritonitis set in, and she died in five days.—*Louisville Medical News.*

A PERVERTED TASTE IN THE FOWL.—It appears that drugs do not enslave man alone. According to Dr. F. A. Seymour, in the *Louisville Medical News*, the hen, of California at least, is very fond of getting intoxicated on belladonna berries. The objection to this is that the berries having first intoxicated, finally kills the injudicious fowl. As emesis cannot be produced and antidotes are insufficient, there is but one method of treatment, which is to open the crop and remove its contents. This has been done very successfully, and a hen supposed to be moribund entirely resuscitated.

CALOMEL AND SODA.—Mr. Hoglan has shown that when calomel and sodium bicarbonate are mixed and triturated, evidence of the presence of corrosive sublimate is obtained in twenty-four hours. The same authority finds that calomel is slowly converted at the temperature of the human body into corrosive sublimate. Chloride of sodium and hydrochloric acid favor this transformation.

These conclusions are at variance with those of Verne, but corroborate those of Herr Slop.

WOMEN DOCTORS OF PHILADELPHIA.—Two lady physicians have recently been elected members of the Northern Medical Society of Philadelphia; and it is said that one has been proposed for membership in the Philadelphia County Medical Society. Our recent report mentioned that several women physicians were admitted as delegates to the Medical Society of the State of Pennsylvania.

THE WISCONSIN STATE MEDICAL SOCIETY held its annual meeting at Milwaukee, on June 7th and 8th, the president, Dr. Ira Manley, Jr., in the chair. The meeting was a large and successful one.

THE EXPANSION OF THE HOMŒOPATHIC MIND is well illustrated by the course of our esteemed contemporary, the *New York Medical (née Homœopathic) Times.* Since it dropped the title "homœopathic" it has been studying to exclude that objectionable word altogether from its columns. And it has even been referring to the American Institute of Homœopathy as the "Institute," adding, of course, the annual announcement that it is the "oldest national medical organization in the country." The *Times* still thinks us trammelled by the absurd traditions of the past, and we think the *Times* and its contributors ought to learn pathology. But progress is affecting everything. It has affected our esteemed contemporary, and we will yet see it print reports of our Pathological Society. The editors announce that they will practise hereafter as regular physicians. The rule (not law) of similars will be used in selecting remedies only when such rule seems advisable. The homœopathic materia medica, we are told, is largely an imaginative work; it contains a frightful bulk of non-essentials and unproved statements. They believe in no medical dogmas, and assert that medical knowledge and skill are the only tests of the physician. Homœopathy, as a distinct school of medicine, has ceased to exist among educated men. This is what the *Times* says, or means, and we can say no more.

THE IMPURITIES OF CROTON WATER.—At a recent meeting of the New York Microscopical Society, Mr. J. D. Hyatt spoke of the disagreeable odors that developed in Croton and other waters in the spring. He said that in early spring the beds of all the mountain brooks which feed the lakes become covered with a gelatinous layer of minute vegetable organisms, the layer being sometimes a quarter of an inch thick. A very little of this jelly mass placed in a vessel of water will soon impart to it the same odor that is observed now in Croton. The amount of organic matter causing this odor is very small by the time the water has reached this city, and it cannot be detected by the microscope. It may be presumed that there is nothing dangerous in the impurity. The observations of Mr. Hyatt were confirmed by Mr. Van Brunt.

PREVENTING ADULTERATION.—A bill to prevent fraud in the adulteration of sugar, syrup, molasses, etc., has passed the State Senate.

SANITARY LEGISLATION IN WISCONSIN.—The Legislature of Wisconsin has enacted a law to prevent the spread of contagious diseases. It forbids the transportation of any dead body within the State borders, unless accompanied by a certificate showing cause of death. It also inflicts a penalty upon physicians in case they conceal any case of infectious disease; and provides penalties for persons suffering under infectious disease who knowingly expose themselves.

ACUTE ALCOHOLISM SIMULATING HYDROPHOBIA.—In view of the frequent appearance of reported cases of hydrophobia, many of which seem to be somewhat doubtful, Dr. W. B. Hazard publishes in the *St. Louis Clinical Record* a case of the above character. The patient suffered for several days from pharyngeal and laryngeal spasms, and had not been able to swallow any liquids. He was at first rational and had no tremor. In a short time, however, furious mania developed, which ended in chonic convulsions and death. Post-mortem showed no characteristic changes anywhere. His previous history showed him to have been a hard and constant drinker.

## JARVIS' OPERATION; ITS RELATION TO NASAL CATARRH.

By F. H. BOSWORTH, M.D.,

LECTURER ON DISEASES OF THE THROAT IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

In a paper read before the American Laryngological Association in New Nork, on June 2, 1880, and published in the *Archives of Laryngology* for April 1, 1881, Dr. Wm. C. Jarvis, of this city, presented a most ingenious wire-snare ecraseur, devised for the purpose of removing the hypertrophied mass which presents so prominently at the posterior termination of the lower turbinated bone in hypertrophic nasal catarrh; together with the indications for the operation. To Dr. Jarvis is due the credit, I believe, of first calling attention to this feature of nasal catarrh, and also of presenting an instrument for dealing with it which fulfils every requirement in a most admirable manner. It should be stated, however, that Bigelow,* in demonstrating the erectile tissue which he finds upon the turbinated bones, calls attention to the fact that when this tissue is artificially distended by a blow-pipe, "a pouch-like process projects from the rear of the bone, increasing its length." Since this paper was published I have performed Jarvis' operation in a very large number of cases, and with such unvaryingly favorable, and oftentimes brilliant results, that I am induced to call renewed attention to the procedure, in part because I regard it as one of the most promising advances that has been made in the treatment of this obstinate disease, but mainly because in many of the details of the operation, its indications and results, I differ from its originator.

The following cases are selected somewhat at random from my note-book, as illustrating many of the points that I desire to make prominent, and are therefore related somewhat in detail.

Case I.—Miss W—— consulted me on August 17, 1880, with the following history: In 1874 she commenced training her voice, which had been pronounced an unusually promising one. Her study progressed favorably, and in the fall of 1879 she accepted the position of soprano in one of our church choirs. During this time she was conscious of a moderate nasal catarrh, but it does not seem to have caused any marked impairment of voice, until about two months after she commenced her engagement, when she noticed that her voice was becoming weak, with a decided loss of brilliancy in the upper notes, particularly in *staccato* movements. There was also a weakness in all the purely head tones, which seemed to increase. She had previously possessed a long respiration, but to control the voice was now obliged to breathe frequently. After singing any length of time she experienced a sense of fatigue in her throat and chest, hitherto unknown. In February, 1881, she caught a severe cold, which developed in an attack of acute follicular tonsillitis, from which she recovered at the end of three weeks. This attack left her voice in a still more impaired state, so much so that she was compelled to cancel her engagement. Rest and mountain air were advised by her physician and tried, but without avail, and her voice seemed irretrievably lost.

On August 17, 1880, she came under my care, when I found, on examination, a moderate hyperæmia of the larynx; a chronic catarrh of the pharynx, with moderate enlargement of the glands at the pharyngeal vault; and hypertrophy of the nasal mucous membrane, involving each middle turbinated bone, and more markedly the lower, at the posterior termination of which were seen the characteristic masses. These masses, however, were small, about the size of a small raspberry, and with my experience at that time the indications for an operation did not seem sufficient. She was treated for ten weeks by applications of acetic acid to the turbinated bones, together with astringent sprays to the larynx and pharynx. Under this plan she seemed to recover, and on November 1st was discharged apparently well. In April, 1881, however, she returned to me, a typical illustration of the oftentimes ephemeral character of many of our cures of catarrh accomplished by local and superficial remedies, for in this case the treatment had really consisted in local applications which were superficial to an extent in their action. Her old symptoms had all returned. I now concluded to perform Jarvis' operation. On April 9th I operated on one side, consuming an hour and a half in the procedure. There was slight hemorrhage at the time, and after waiting a half hour she left the office and went shopping. While on Broadway, about two hours after the operation, a hemorrhage set in, but not very excessive; so, with the bleeding going on, she made her way home and sent for her physician. The bleeding proved obstinate, and persisted intermittingly for thirty-six hours. The result was exceeding prostration, bringing on an attack of tonsillitis, from which she recovered at the end of three weeks. I saw her again after her recovery on May 2d, when she presented with a relaxed throat and a train of discouraging symptoms. I proceeded, however, to complete the operation on the other side. I now placed the wire loop *in situ*, and drawing it tight I allowed it to remain, and giving an occasional slight turn to the screw, occupied three hours in the procedure, my patient sitting in an easy chair behind a screen in my office and reading the morning paper while the snare projected from the nose. There was no pain and but trifling discomfort.

At the end of three hours the loop was drawn home and the instrument was withdrawn. There was scarcely a drop of blood, and the severed mass was left in the nose. I directed her to refrain from blowing the nose for the day and to see me the next day, when she came, bringing the tumor, which had dropped out during the same evening, and reported that there had been absolutely no bleeding or any unpleasant symptoms whatever from the operation.

The patient was seen twice each week for a few weeks, and was dismissed in early June entirely well, both from rhinoscopic examination and clinical symptoms. Writing to me since, she reports that she is now "convinced that the compass and quality of her voice are fully restored," and she is singing again with her accustomed ease, and that the *staccato* movements are accomplished with a clearness and brilliancy which she has not possessed for years. She very graphically describes her former efforts as similar to those of a violinist attempting to produce a brilliant and powerful tone with a padding on the bridge or sounding board of his violin.

It may be said of this case that she was cured once before, and that the trouble may recur, as formerly. There lies this difference, that the symptoms were removed only in the former case, while, by the operation, the prominent morbid condition which

* Boston Med. and Surg. Journal, April 29, 1875.

gave rise to the symptoms has been removed. I believe this to be a permanent cure, for, as I shall notice further on, the operation on the lower turbinated bone exercises a positive action on the erectile tissue of the middle bone. I have reported the above case at length, and with an amount of detail which may seem tedious, but to me it was an exceedingly instructive case as bearing on many points.

The human larynx is the most perfect musical instrument that has ever been created, not only technically, but in its flexibility, its capacity of expression, and above all other considerations, in its power of conferring happiness. The physician's art loses nothing of dignity, therefore, if, going beyond the mere practice of health-restoring, the study is added of the development, culture, and preservation of this most perfect function of the larynx—the singing voice. The sounding-board function, as it were, of the pharynx and nasal cavities is one whose importance in vocalization cannot be overestimated. The first impulse of the vocal waves is upon the pharyngeal vault, from which they are reflected into the nasal cavities. This does not apply so prominently to the chest-notes, but is of exceeding import in regard to the head-notes. Now, if the nasal lining membrane be the seat of a chronic inflammation resulting in hypertrophy, this sounding-board function is necessarily to a greater or less extent impaired. The singer, unconsciously perhaps, by an exaggerated effort of the respiratory muscles, endeavors to compensate for this deficiency by driving a more powerful current of air through the glottis. The result is obvious: the chest muscles become soon weary, the vocal muscles become tired by the increased tension rendered necessary, and a laryngeal hyperæmia ensues, involving the danger of a laryngeal catarrh and permanent impairment of voice. The same line of reasoning applies with even greater force to the existence of the thickened masses on the lower turbinated bones posteriorly, lying as they do in a position to shut off the nasal cavities from the pharynx, and to completely interrupt the vocal waves in the head-register.

Another point, I think, is well illustrated in the above case, and that is the influence of nasal catarrh upon the air-passages below. I have always, in my teaching, laid especial emphasis on the fact that, in the very large majority of instances, a laryngeal catarrh is the result of a nasal catarrh. In singers, this result is caused often in the manner above alluded to. It may occur also by mouth breathing caused by nasal obstruction; by the irritation of the discharges making their way from the nose into the larynx; and finally, by a direct extension of the catarrhal process.

Case II.—Mrs. W—— came under my care September 22, 1880, with a history of a throat catarrh of six years' duration. Her main annoyance has been from the accumulation of thick tenacious mucus in the fauces, which she could only dislodge by violent effort. She was liable to take cold easily, and her recurrent attacks seemed to attack regions lower down in the air-passages each time. She had been under the care of a number of physicians, and had been subjected to numerous plans of treatment. An examination revealed a chronic catarrh of the pharynx and larynx, with thickening of the nasal lining as seen anteriorly. A rhinoscopic examination was rendered impossible by an exceedingly irritable throat. I treated her for three months with local astringents and gave marked relief, but failed to effect a permanent cure. During this time, the most patient effort failed in giving me a view of the posterior nares, and finally, in March, I determined to use the snare as a searcher, and to test the existence of a posterior turbinated hypertrophy by it. The loop became engaged after one or two trials, and tightening it I slowly severed the mass, occupying an hour and a half. There was but slight hemorrhage at the time, and she left my office. Three hours afterward I called upon her and found that an hour after she left me her nose had commenced to bleed and had continued without cessation. I immediately plugged the nares from in front and arrested the bleeding. The plug was removed on the second day following, but hemorrhage recurred, and I plugged again, and allowed the plugs to remain until the fourth day. Ten days later I operated on the other nostril, and consumed three hours in severing the mass. The procedure was accomplished with no pain, discomfort, or hemorrhage, during the operation or subsequently. I saw the patient but twice afterward for treatment, when she was discharged cured. She reports to me a week ago that she was entirely free from any trouble with the throat, and that the operation had accomplished for her what all her previous treatment had failed to do. It should be also stated that this lady was a fine reader, but had been compelled to abandon it on account of her voice becoming weak and husky on slight exercise. She reports this difficulty entirely removed.

Case III.—G. W—— came to me from Northern New York, on March 30, 1881, to consult me on account of a nasal catarrh of seven years' standing. He had used douches and snuffs, and various devices for its relief, but without avail. He was also the possessor of a fine tenor voice, but for two years had not been able to sing, his voice, as he expressed it, was entirely gone. He complains of a constant dropping in his throat, which is the source of great annoyance. An examination revealed a chronic catarrh of the larynx and pharynx, with moderate hypertrophy of the membrane covering the middle and lower turbinated bones, with masses on the latter about half filling the posterior choannæ. I advised an operation and with his assent, immediately proceeded to remove one mass with the snare. I consumed an hour and a half in the procedure, and there was no hemorrhage. Four days later I operated on the other side, consuming the same time. Violent hemorrhage immediately set in, which required plugging. The plugs were allowed to remain forty-eight hours. I treated him subsequently for three weeks with local astringents to overcome the moderate disease of the upper turbinated bones and the larynx, and finally discharged him cured.

This was a typical case of nasal catarrh, illustrating the effect of the disease in causing laryngitis, and also the fact which I believe to be true, that a large proportion of the excessive discharge in this disease has its source in these enlarged masses on the lower turbinated bones, and that in their removal we radically remove the disease itself. I might report a large number of cases whose results are in every way as flattering as those narrated, but I have already written at greater length than I intended. It remains to draw some general conclusions.

*The indications for the operation.*—In every case where there exists a mass that will engage the snare it is a morbid growth and should be removed. I believe that the indications for the operation are as prominent as those for the operation of tonsillotomy, and that the results to be obtained are quite as favorable in the one case as in the other.

*Hemorrhage.*—By far the most troublesome feature

of the operation is in the hemorrhage, and in some cases it seems very difficult to avoid it, for the cut surface not only extends through the congested blood-vessels of the mucous membrane, but also into the enlarged and dilated blood-spaces, which make up the erectile tissue which underlies the mucous membrane. As will be seen, the hemorrhage from this source is not only profuse, but is to an extent intractable, for it is not amenable to astringents or hemostatics. The only resource is to so accomplish the operation that the edges of the cut surface shall remain in apposition, or to plug. I have, in every case where it became necessary, succeeded in plugging from in front, thus avoiding the troublesome manipulation of Bellocq's canula, or other devices of the kind. Knowing the exact source of the bleeding, it is quite feasible to pass, successively, small pledgets of cotton through the nostril, back to the cut surface, where they can be wedged between the turbinated bone and the septum. It is not safe to remove the plugs in less than forty-eight hours. It is important to count the pledgets as they are introduced, as the knowledge is of value when it becomes necessary to remove them.

*The operation.*—Dr. Jarvis recommends the placing of the loop of the snare by means of the rhinoscopic mirror. I have in no instance found this necessary. In many cases it will be impossible. Dr. Jarvis calls attention to the fact, that, as this hypertrophy develops, it grows backward, projecting into the pharynx, and that thus there is formed a deep sulcus between the mass and the side of the pharyngeal wall. The existence of this sulcus renders the operation by the snare not only feasible, but extremely simple. It is the only point which can engage the loop of the snare. In a healthy nose there is nothing which will engage the loop. Hence it follows that nothing can be seized which should not be removed, and, further, that anything in the nasal cavity, which can be engaged by the loop, is a morbid growth and should be removed. There is, therefore, no danger of doing any damage to healthy structures. Furthermore, it is quite feasible to use the snare as a searcher, as was done in Case II.

It is the great advantage of Jarvis' instrument, that it is mounted with steel piano wire, which furnishes a loop which is so resisting that it can be easily manipulated. Furthermore, it possesses a bend, given it by the coil in which it comes, so that as it is projected from the instrument, the loop curves to one side. In operating, the proper-sized loop is adjusted to the instrument, and is then drawn into the canula until a small loop projects, which will pass through the nostril. This is then passed through the nares until it reaches the pharynx. The wire is now played into the canula, thus enlarging the loop in the pharynx. If, now, the instrument has been entered in such a way that when the wire loop emerges from the distal end of the canula it will bend around toward the turbinated bone, it will be seen that as it is slowly withdrawn the wire will fall over the tumor and into the sulcus between it and the wall of the pharynx. Holding the canula steadily in the left hand and turning the screw, and at the same time pressing the distal end of the canula firmly against the turbinated bone, the mass will be constricted. The screw should be now turned until the resistance is very great, when the patient should lie down and make himself as comfortable as possible. The passing of the instrument is unpleasant, but the irritation will soon pass away. The tightening of the loop is quite painful, but the pain lasts but a moment. The loop should be slowly tightened by, say a half turn of the screw every five or ten minutes, and at least two hours or, better still, three hours consumed by the operation. There are two objects accomplished by this; one is the avoidance of hemorrhage, and the other is the avoidance of an open cut surface. This latter I regard as important. The parts are drawn up by the loop much like the puckering string of a bag. If, now, they are held in this position for, say three hours, they become agglutinated together in such a way, that when they are cut through they remain in apposition and do not open out again. There is then avoided an open cut surface, which may occupy several days in healing, and during that time prove the seat of pain and irritation. That the parts are cut through will be known by the sudden cessation of resistance in turning the screw. The part should be kept quiet several hours after the operation and the nose should not be blown. If the severed mass does not come out on the instrument, it had best be left *in situ* until it drops into the pharynx, though it probably would not be well to leave it in during sleep.

*The results of the operation.*—These have been fairly brought out by the cases. They may be summed up as follows:

*First.*—The removal of a most serious obstacle to a full rich tone, especially of the head-notes in the singing voice.

*Second.*—The removal of a serious menace to the integrity of the singing voice.

*Third.*—The removal of a prominent feature of nasal stenosis, which sooner or later will develop a pharyngeal and laryngeal catarrh.

*Fourth.*—The removal of what is largely the source of excessive secretion in nasal catarrh.

*Fifth.*—I am convinced that the removal of the mass by the above method, cutting into the erectile tissue, diminishes the tension of the blood-spaces and affords relief to the mucous membrane beyond the seat of operation; and, still further, that the traction exercised in drawing the membrane into the loop of the snare, exercises a beneficial action in the whole length of the turbinated bone. I have certainly seen a puffy thickening of the mucous membrane anteriorly relieved by removal of the hypertrophied mass posteriorly.

26 West Forty-sixth Street.

## A SECOND SERIES OF STONE OPERATIONS.*

By A. VANDERVEER, M.D.,

Albany, N. Y.

In the *Archives of Clinical Surgery* for October, 1876, I presented a paper on the "Operation for Stone, with a Report of Cases." To that report I wish now to add other cases, some of which show so markedly the improvement that has taken place in the treatment of vesical calculus, an improvement mainly due to the efforts or Prof. Henry J. Bigelow.

Case I.—*Gun-shot wound of the bladder accompanied with fistulous tract; subsequent formation of vesical calculi.*—W. R——, American, thirty-five years of age, married, came under my care in the spring of 1873, giving the following history: As a private in a New York regiment he was wounded on the 30th of June, 1863, through the bladder. From that time on his life has been one of great suffering, and in his repeated efforts to obtain relief from pain, he has become a confirmed morphine eater. The

* Read at the meeting of the New York State Medical Society, February, 1881.

amount he has taken and is now taking is almost incredible. He is very much emaciated, has but little appetite, is passing his urine very frequently, mostly through the sinuses, and in every respect is a most pitiable object. A careful examination of his urine shows a large amount of albumen, considerable pus, but no casts. Giving him ether and sounding his bladder revealed the presence of stone. At different times since his wound was received he has passed from the urethra phosphatic concretions, and from the sinuses necrosed pieces of bone, small particles of lead, and portions of clothing, which I have shown you. He states that the ball was never found. I saw Mr. R—— occasionally during the summer of 1873, and though an earnest effort was made in various ways to improve his condition, yet his system never seemed sufficiently strong to undergo the operation of lithotomy.

He died October 26, 1873, and the following is the report of the autopsy: Post-mortem rigidity well marked. There was a bed-sore back of and below the trochanter major on the right side. Cicatrix and mouth of a fistula below Poupart's ligament on the right side, one-third of the way from the symphysis pubis. Body much emaciated. The course of the ball was just below Poupart's ligament, near the pubic symphysis on the right side, and passing through the horizontal ramus of the pubic bone, it entered the posterior portion of the bladder, passed out and through the tuberosity of the ischium, was then deflected upward, and finally lodged behind the trochanter major of the left femur, where it was found firmly encased in a fibrous covering. The bladder was divided into two parts by cicatricial tissue and fibrous bands apparently in the portion of the bladder through which the ball had passed. The anterior half of the bladder contained a large calculus, the posterior portion a smaller one. The calculi are soft and phosphatic in character. The fistulous tract on the right side connects with the bladder just in front of the opening of the right ureter by a smooth valvular orifice. The coats of the bladder were much thickened. The ureters were dilated so as to admit the passage of the little finger. The pelves of both kidneys were dilated and there was slight contraction of the parenchyma; general structure of the kidneys, however, was normal. Capsule not adherent, peeling off easily. Thoracic viscera healthy. Encephalon not examined.

Weight of large calculus, 405 grains (26.244 grammes); weight of small calculus, 132 grains (8.553 grammes); weight of ball, 480 grains (31.175 grammes).

Case II.—*Calculus in the inferior fundus of the bladder.*—Mr. G——, seventy-two years of age, married, very fleshy, and usually in good health. Dr. Snow and myself saw him for a few days previous to his death, June 10, 1876. He gave no marked symptoms aside from a desire to urinate often, and sounding the bladder failed to reveal stone. At the autopsy, the following condition was found: Body very fleshy. Pleural surfaces adherent on both sides, but more firmly on the right. Liver cirrhotic. The kidneys, buried in an immense bed of fat, were contracted and also covered with numerous cysts. The heart was in a condition of fatty degeneration. The bladder was contracted, and contained, in a sac-like depression, just back of the isthmus of the prostate gland, a small stone, weighing seventy-one grains (4.6 grammes), and made up principally of the phosphates. The prostate gland was much enlarged. This case, together with others, leads me to believe that many old gentlemen, who are suspected of having only hypertrophy of the prostate gland, also carry about with them partially encapsuled small vesical calculi. Had we discovered the stone previous to his death, his condition was such that an operation would hardly have been advisable, even by the Bigelow method.

Case III.—*Large calculus in a female; lithotrity and washing out of the fragments; recovery.*—Mrs. Y——, sixty-five years of age, married, and the mother of five children. Fifteen years ago she had an attack of renal colic, and at that time passed several small calculi, entirely recovering from the attack, however. Three years later she had another attack, and since that she has suffered with all the symptoms of a vesical stone, with chronic cystitis.

I first saw the patient with her family physician, Dr. Werner, of Cobleskill, N. Y., January 18, 1877. Dr. Werner had previously diagnosed vesical calculus. On sounding the bladder, it was evident there was a large stone present. For the past year she has been compelled to push it back with a silver female catheter, whenever she desired to urinate. A previous examination of the urine showed the kidneys to be healthy. The patient was operated upon, January 18, 1877. Using Teevan's lithotrite, the stone was crushed several times and the fragments washed out with Davidson's syringe. First, however, I dilated the urethra with Heath's urethral dilator, so that I could introduce the index finger of my right hand.

The operation lasted nearly an hour, the patient bearing the ether only fairly well. My first impression was to do a vaginal lithotomy, so well spoken of by Dr. J. Collins Warren, of Boston, but the patient was so very fleshy as to make it quite impossible to reach the parts. The stone was phosphatic in character, a distinct nucleus being found, which was probably a renal calculus. Some of the detritus was lost by overturning a basin of water containing it; that which was saved, however, weighed three hundred and twenty-eight grains (21.254 grammes).

During the afternoon following the operation the patient suffered from a severe pain in her back, and also vomited some. The vomiting, however, was soon controlled. Up to the evening hour there had been no sign of chill. On the morning of the next day, January 19th, she was feeling comfortable; her skin was moist, and her pulse 92. She controlled her urine quite well, although its voiding was attended with some smarting and burning. She slept well, and, indeed, passed quite an easy night. On the evening of the same day (January 19th), the patient was again seen by Dr. Werner. She had passed through the day very well; was able to retain her urine about an hour, at the end of which period she experienced a severe smarting and burning pain. At 8 P.M. the pulse was 100; skin still moist, and tongue coated. There was also increased thirst, and some distress at the stomach. No sign of a chill, however. She was given quinine and iron every three hours, and morphine at greater intervals. Flax-seed tea was also freely administered. On January 20th the patient continued comfortable, and slept well during the previous night. Her pulse was about 90, and there was less moisture of the skin. She was now able to retain her urine for an hour and a half. In washing out the bladder, however, she experienced much distress. The stomach was quite irritable, also, but altogether the symptoms were quite favorable. On January 21st, the patient complained of considerable gastric disturbance. She experienced great relief from an evacuation of the bowels, the first

movement obtained since the operation. There was still some thirst, though not so marked as heretofore. Pulse 92. She seemed to rest well, but complained of feeling tired. The washing of the bladder was on this day omitted.

January 23d.—She expressed herself as feeling better. Pulse 88. Another evacuation from the bowels was obtained, also the bladder was again washed out. The passing of her urine was now accomplished with less pain than previously. On the 24th the patient still continued comfortable. Pulse 84, skin natural, and the tongue, which had been much furred, was cleaning. Her appetite had also improved. Quinine was continued, also one-fourth grain morphine three or four times daily. Bladder was now washed out each day. The scalding and burning were much abated and the urine much less offensive than at first. The first two washings brought away several pieces of calculus; none have appeared since, however. On January 25th the patient was able to retain her urine for a period of three hours. She rested well during the night, but was at one time somewhat chilly, a condition due, however, to an exposure to a current of air. As she was immediately warmed nothing serious resulted. Her pulse was now 80, her appetite improving, thirst much less urgent, and all her symptoms, indeed, were quite favorable.

January 26th.—The patient had slept well during the night and was still, at 10.30 A.M., resting nicely. Pulse 85, skin natural, and the appetite continuing to improve. The quinine disagreeing, it was now discontinued. After washing out the bladder another quite large piece of calculus was passed, so large, in fact, as to cause much pain as it was being discharged.

On January 27th the patient reported the previous night as decidedly the most restful she had had, and she had been able, also, to retain her urine for the period of ten hours. The pulse was 80, tongue continuing to clean, skin quite natural, appetite increasing, the gastric irritation mostly allayed, and the general appearance much improved.

Mrs. Y—— made a good recovery and was in perfect health when last heard from a few months since.

CASE IV.—*Synoptical history; renal colic; stricture of the urethra; calculus lodged behind the stricture; internal urethrotomy; removal of stone; recovery.*—Mr. C——, aged thirty-six, by occupation a wood-cutter in the North Woods, was admitted to St. Peter's Hospital, December, 1876. History: Twelve years ago he contracted gonorrhœa and was a long time in recovering from it. Nearly three years ago he had an attack of renal colic connected with the left kidney, and soon after found that he had increased difficulty in passing urine, the stream at times being much reduced in size. About six months later he was able to feel a hard substance in the perineum, and from that time on he has had serious trouble in emptying his bladder. For the past few months he has been unable to work. An examination with bulbous bougies detected a stricture two inches down in the spongy portion of the urethra and another in the membranous portion, through which latter only a whalebone guide could be made to pass. As the guide passed the second stricture it revealed a calculus in either the membranous or prostatic portion of the urethra. The calculus could be felt from without also. An examination of his urine showed no organic disease of the kidneys. He was given five grains quinine three times daily, and ten minims tincture ferri mur. for two days, and on December 18th was put under the influence of ether. The stricture, two inches from the meatus, was divided by Otis' urethrotome, then a guide was passed through the lower stricture. On this was passed a Maisonneuve tunnelled instrument and the stricture cut. Thompson's long, slender urethral stone forceps were now passed easily down the urethra and this stone removed, oblong in shape, as you see, and measuring in its long diameter one inch, circumference three-fourths of an inch, and weighing forty-one grains (2.65 grammes). The stone is composed chiefly of oxalate of lime with a crust of the phosphate. This patient had one chill a few hours after the operation, but by aid of full doses of quinine and iron he went on to a perfect recovery. The strictures were treated by passing full-sized steel sounds twice a week. The bladder was afterward examined with Thompson's short-beaked searcher, but nothing was found. Previous to removing the stone it became necessary to incise the meatus slightly. The patient was discharged, cured, in March, 1877.

CASE V.—*Calculus in a girl; rapid dilatation of the urethra; removal of stone entire; recovery.*—July 21, 1879, I was requested by my friend, Dr. Barker, of this city, to see Miss W——, aged five years, who had been suffering nearly two years with bladder trouble. I found her in bed with her clothing wet, her mother stating that the little girl was passing her water constantly in great pain and that it was impossible to keep her dry. On examination of the bladder we could detect a stone. She was given two grains of quinine three times daily and an anodyne night and morning, and on July 23d we proceeded to operate. She was given chloroform, the urethra was quickly dilated with Heath's dilator, and with small stone forceps this calculus, weighing forty grains (2.592 grammes), was removed. It is composed of oxalate of lime, and, as you observe, is covered with numerous little spines, which must have caused much pain. Quinine was continued, also demulcent drinks, and I am informed by Dr. B. that the little patient went on to a rapid recovery.

CASE VI.—*Large urethral calculi removed by external perineal incision; recovery.*—Mr. A. F——, aged nineteen years, was admitted to the Albany Hospital, March 29, 1879, as a case of urethral stricture. The following was the history obtained: Ever since his third year the patient had been troubled with painful micturition, a burning, stinging sensation just after the act. He had also been compelled to get up during the night two or three times to pass urine. On examination it was found impossible to pass any instrument on the first trial, and as further attempts gave him great pain, it was decided best to wait, anæsthetize him, and make the examination a thorough one. The perineum was enlarged, as was also the inferior wall of the urethra along the lower half of its course. Hot applications were made to the parts and covered with oil silk. On the 5th of April the patient took, at 10 A.M., ten grains of quinine and at 12 M. was etherized. An exploration of the urethra revealed calculi. A grooved sound was then passed and an external perineal section performed, the incision being about one and a half inches in length. By aid of the sound, the fingers being introduced into the rectum, a large smooth calculus was expelled from the cut and was directly followed by a second one. The wound was left to itself, a little lint being applied to soak up the oozing of blood. Hemorrhage was slight. The patient was placed in bed, wrapped in warm flannel and kept under quinine.

April 26th symptoms of cystitis were noted. I ordered a warm sitz-bath and a prescription of potassium bicarbonate, and hyoscyamus.

May 19th, the patient was etherized and Nos. 10 and 16 English steel sounds were passed.

June 9th, the patient was discharged cured. He was ordered to have full sized steel sounds passed at least once a week. The calculi are mostly phosphate of lime. The larger one weighs four hundred and seventy-five grains (30.78 grammes), the smaller two hundred and forty grains (16.2 grammes). It will be observed that the larger stone is a perfect cast of the distended prostatic portion of the urethra, even presenting the impression of the opening of the ducts. And notice also that the facet of junction of the two stones at the greater curvature of the urethra is very perfect. These are remarkable specimens of prostatic or urethral calculi and undoubtedly were lodged there when the boy first presented symptoms at the age of three years.

CASE VII.—*Stone found at a post-mortem.*—Mr. M. H——, married; aged sixty-five years, was seen a short time previous to death by Dr. Snow and myself. He gave the history of urethral and bladder trouble extending over a period of fifteen years. His condition was such that no very thorough examination of his case could be made. His urine on examination revealed a large amount of pus and albumen. Under the microscope crystals of oxalate of lime and pus were found, but no casts. I was reminded by the son that I had treated him five years before for abscess of the kidney, whereupon I expressed myself as desirous of being informed of his death whenever it should occur. The patient had been treated also for attacks of bilious colic. He died July 25, 1879, and the autopsy was made at 4 P.M. next day. The following is a brief report: Peritoneum thickened; bladder distended and partially adherent to peritoneum. The middle lobe of the prostate gland was enlarged and had attached to it a diseased mass, behind which was a calculus about the size of a walnut. This diseased mass seemed to be a non-malignant ulcer. Left kidney was contracted and filled with calcareous deposits, while the right was enlarged and filled with pus and abscesses. There were evidences of pleurisy on the right side, there being slight adhesions at apex and side of right lung. Gall bladder was filled with calculi as was also the cystic duct.

The weight of the stone is eighty-four grains (5.443 grammes), and is phosphatic in its make-up.

CASE VIII.—*Portion of chewing-gum introduced into the bladder; removed by Bigelow's method; recovery.*—Mr. A. S——, twenty-four years of age, single, was admitted to the Albany Hospital, September 5, 1879, and the diagnosis of foreign substance in the bladder made. Six weeks before coming to the hospital the patient had introduced a piece of chewing gum into his bladder. He had been treated, but without success. On September 7th the searcher, a steel sound with short curve, was introduced and the foreign body felt. The next day a consultation of the staff was held, and on again using the searcher the substance could be felt, but when the lithotrite was introduced into the bladder nothing could be found. It was concluded to wait a little. On the morning of September 9th the patient had a severe chill. Cinchonidian sulphate was freely given and continued in two-grain doses every two hours. September 13th the searcher was again introduced, and the body could be distinctly felt, indeed an audible click was emitted by the incrusted salts of the urine. On September 14th he had another chill. On the 17th the patient was put under ether and with the lithotrite pieces of the salts incrusted about the gum were brought away. Bigelow's evacuating-tube, No. 29, was introduced into the bladder, and his suction-apparatus, filled with water, was attached. The water was gradually forced into the bladder, and as it returned the gum came with it, thus making the operation a complete success. The patient was put to bed and ten grains of quinine given him. The cinchonidia was continued as usual, two grains every four hours. About 11 A.M. September 18th the patient had a severe chill. Ten grains of quinine were given and warm applications made. At eight o'clock P.M. another chill occurred. Temperature was 105° F.; pulse, 150, and perspiration very profuse. After the 18th the patient had had no chills, and his improvement was continuous up to September 24th, on which day he was discharged cured. The gum, together with the crust of phosphates, weighs twenty-nine grains (1.879 grammes). For this case no instrument could have taken the place of the Bigelow apparatus. The soft gum filled the jaws of the Teevan lithotrite, and it would have been impossible to have gathered it in that way. Moreover, it probably could not have been pulverized sufficiently for it to have been washed out with a double catheter or evacuated with the urine.

CASE IX.—*Large phosphatic calculus; cystitis; great amount of pus in the urine; medio-lateral lithotomy; recovery.*—Henry M——, M.D., forty-two years of age. Two years ago last October, while visiting a patient during a rain-storm, Dr. M——, the patient, caught cold and had an attack of acute cystitis. His professional duties did not allow him to get entirely over his ailment before he again went to work, and he thinks riding aggravated the trouble. At times he had been troubled with spasms of the bladder, making it necessary to pass a catheter. This operation, however, was so painful upon these occasions as to necessitate the administration of chloroform previous to the introduction of the instrument. At times also there have been a great deal of pus and mucus in his urine, and its condition so acid as to scald severely on passing it. To relieve the burning he was constantly in the habit of taking alkalies, morphine, chloroform, etc. He further complained of considerable pain in the end of his penis.

On October 12, 1879, the patient was put under ether and the urethra and bladder examined. A number of strictures were found in the urethra. An Otis' instrument was passed and the stricture in the spongy portion cut. One or more deeper down were of large calibre, and admitted a No. 12 sound. A Thompson's searcher was passed into the bladder, and a calculus of quite large dimensions was found. With the lithotrite it seemed to be over two inches in length and more than an inch in its shorter diameter. The patient was then allowed to come out from the anæsthetic and was given five grains of quinine. Having a slight chill at 6.30 P.M., five grains more of quinine was given. This latter dose was vomited, however. At 9.30 the patient was doing nicely.

October 18th.—The patient was put under ether, and the medio-lateral operation for lithotomy by the rectangular staff done. Owing to the size of the stone it was found necessary to crush and remove it in fragments. Length of operation forty-five minutes. After the operation the hemorrhage became rather

unpleasant, and the patient was again put under ether and another ligature applied, which, in addition to plugging the wound, controlled the bleeding. The manner of making the plug, by Dr. S. B. Ward, was as follows: A circular piece of oilcloth was passed over a catheter and tied firmly; the catheter was then passed into the bladder, and the space between it and the oilcloth firmly packed with lint. The plug was removed October 19th, the patient doing nicely and passing urine through both urethra and wound.

On October 31st the urine passed entirely through the urethra. It was nearly one-third pus and mucus.

November 4th.—The urine was passing nearly clear. The neuralgia was also diminishing. On this date a catheter was passed, after which urine escaped from the wound for a short time. Patient continued taking twelve grains of quinine in twenty-four hours. On November 7th the patient came down-stairs for the first time since the operation, and on November 8th he attended a clinic. At this date he was troubled with incontinence of urine. Pulse and temperature were normal, and he was feeling well. On November 14th he was up and moving about the hospital. Could hold his urine for two or three hours at a time, and the pus had nearly disappeared from it. His bladder was washed daily. On November 18th the urine appeared normal. On the 22d a stricture two and three-fourths inches from the meatus was divulsed and cut with Otis' instrument.

December 3d.—The patient was discharged cured and returned to his home.

The weight of the stone is three hundred and forty-five grains (22.356 grammes). It could easily have been crushed, but in consequence of its size and a severe cystitis, it was thought best to cut. The first objection, viz., the size of the stone, we have learned to be untenable, while the second is still on trial. The following letter was received from Mrs. M——, in reply to one of inquiry from the house surgeon. I feel it my duty to present it, as giving the final results in the doctor's case. I am told by those who saw him after his return home that he was exceedingly careless in the matter of exposure. His death was probably the result of hepatic abscess. The following is a copy of the letter:

"In reply to your postal card, requesting me to tell you something of Dr. M——'s last sickness. I will say he returned from the Albany Hospital the 5th of December, feeling well, and continued to feel well until the 16th of December, when he was taken with an acute pain in the right side under the floating ribs, accompanied with sickness at the stomach, vomiting up all kinds of medicine and nourishment that he took. Two or three days afterward he discovered a swelling in the same place, the size of a large hen's egg, which was very sore. He could not bear anything upon it, even the weight of the sheet was burdensome. The pain gradually wore away, leaving it very sore. After the pain subsided he had a high fever, followed by a sweating stage. About ten days after he was first taken sick he had a hard chill, which lasted twenty minutes, followed by a very high fever and sweating stage. He continued to have chills, fevers, etc., once a day at first, and afterward more frequently, until he died, January 10, 1880. He retained consciousness until about four hours before he breathed his last. I ought to have stated that he had a very sore throat and mouth, which made it difficult for him to swallow. Tongue badly swollen and very sore."

CASE X.—*Large phosphatic calculus; Bigelow operation; recovery.*—Mr. C. H——, aged sixty, was admitted to the Albany Hospital May 26, 1880. About eighteen years ago he began to experience burning sensations about the urethra when passing water, and continued to have them at times, though not sufficiently unpleasant to occasion any particular annoyance up to about four years ago, at which time, after riding over rough roads, he had an attack of hemorrhage from the bladder, lasting for a short period. These hemorrhages would recur regularly every two or three weeks, and continued to do so up to about two years ago. At the time of the first attack of hemorrhage, he had a severe pain in the lower portion of the left lumbar region, which lasted for two or three days, and required considerable doses of morphia to relieve it. Upon his admission to the hospital an examination with a sound was made, when a calculus was both distinctly felt and heard. He was now given ten-grain doses of potass. citrate three times a day. On May 29th he was anæsthetized and a lithotrite passed. After exploring the bladder for some little time, the stone was finally engaged and crushed, the Thompson and Teevan lithotrites being used alternately. The instrument was then withdrawn and litholapaxy practised, drawing away considerable *débris*. (I used in this operation, as well as in my others, the original instrument of Bigelow; but during its use at this time, the rubber bag became loosened from its attachment, thus rendering it unserviceable. I was, therefore, greatly indebted to Dr. Vanderpoel, Jr., for the use of his improved Bigelow apparatus, as also for his personal assistance.) The preceding operations were done consecutively for several times, until the bladder was quite free from foreign matter. He was taken to his room and ten grains of quinine given. He had some vomiting before fully recovering from the effect of the ether. The first night following the operation he had a chill, the temperature afterward rising to 102.5°, and dropping by the third day to 99.5°. On the afternoon of the third day he had a second chill, followed by a temperature of 101.5°, which declined again by the fifth day. The patient was now given five-grain doses of quinine three times a day. On the seventh day he had a chill, followed by a temperature of 103.6°, at which time one-fourth drop each of tincture aconite and tincture digitalis was given every hour, the temperature falling next morning to 101°. By the eleventh day it had gradually reached normal, remaining about so with some slight exacerbations until the evening of the fifteenth day, when, having had another chill, it rose to 103°. On the first of June he was ordered to take triticum repens. On the eleventh of June he was put on tinct. gentian comp. The temperature on the morning of the sixteenth day dropped to 101°, but on the same day, after a slight chill, it again reached 103°. On the seventeenth day it fell to 99°, rising again to 101° in the evening. On the morning of the eighteenth day the temperature was normal, but rose again in the evening to 101°. On the nineteenth day he had a severe chill, which sent the temperature up to 103.5°; it fell next day, however, to 102°. It rose again on the twenty-first day to 103.6°, falling gradually by the twenty-third day to 99.5°; but that evening another chill caused it to rise to 102.5°. By the twenty-fifth day, it had declined to normal. On the twenty-seventh day, he experienced a slight chill, with but little rise of temperature, which subsequently dropped to about normal, and so remained until the day of his discharge, June 30th, when he expressed

himself as being in much better condition, both physically and mentally than he had been before in years.

On July 13th, I received a letter from the patient's family physician, Dr. Merritt, in which he stated that the patient had had a relapse as a result of overdoing, but at the time of writing he was much better and able to be about. With proper care there was no doubt but that he would be as well as ever again. Very recently I received word from the patient himself, to the effect that he was entirely well, passing normal urine in a natural manner and again attending to business. The detritus weighs three hundred and eighty grains (24.624 grammes), and is entirely phosphatic. But very few cases have been reported where so large a stone has been successfully treated by the Bigelow operation.

CASE XI.—*Small phosphatic calculus; Bigelow operation; rapid recovery.*—Mr. R. S. P——, aged fifty-three, was admitted to the Albany Hospital September 13, 1880. History: about three years ago the patient first noticed that he could not pass water as readily as usual. This slight impediment to the emptying of his bladder remained for a while, and then there gradually came on a feeling of weight and dragging pain in the region of the bladder, and some pain radiating up the tract of the ureters. About eighteen months since, while urinating with the usual resistance, he noticed that a bloody discharge was escaping from him. This was the only time, however, that blood ever passed him. He has complained of pain in passing urine ever since he first observed anything wrong. For the past three months he has had to draw his own water by means of a catheter. There was no suspicion in his mind as to the nature of his trouble until recently, when on sounding him I discovered a calculus of small size and suitable for the operation of litholapaxy. This operation was performed September 18th, and a number of fragments of a phosphatic variety removed. The patient since has been doing very well. Cinchonidiæ sulph, in two grain doses, three times daily, has been given. His temperature upon the evening of the operation was 102°, and pulse 100. These fell the next morning, the temperature to 99.6°, and the pulse to 80. The evening of that day (the 19th), however, they rose respectively to 101° and pulse 85, falling again to 99°, pulse, 70. After this for a few days the temperature ranged between 99° and 100°. There were no signs whatever of a chill after the operation. His urine was drawn off when required to be. About eight days after the operation the bladder was washed out and sounded, but nothing was found. Since then the washing was repeated once a day, nothing but a little mucus making its appearance in the urine. The patient was discharged October 2d, 1880, having been in the hospital nineteen days in all, and but fourteen since the operation. He came to my office recently, saying he was feeling well. Could urinate in a natural manner, had none of his old symptoms. On sounding the bladder it was found free from any deposit. Weight of detritus was sixty grains (3.888 grammes).

A somewhat remarkable feature of this case was the fact of his having retention of urine while a stone existed in the bladder.

While the Bigelow operation has been so very successful, yet in the cases here presented, the chills following the operations have been a very great source of anxiety. In performing the operations here spoken of, I am greatly indebted for assistance to my colleagues, Drs. Ward, Snow, Mosher, Curtiss, and Hailes, and the faithful house-physicians of both hospitals.

## THE NEW YORK STATUTES FOR REGULATING THE PRACTICE OF PHYSIC AND SURGERY.

By EDWARD B. MERRILL,

ATTORNEY AND COUNSELLOR-AT-LAW, NEW YORK.

(Continued from p. 11.)

"SINCE the passage of the act of 1844 (which has already been given), quackery may certainly boast its triumphant and complete establishment by law. But, notwithstanding this, a brief retrospect of the course of legislation on this subject may not only be useful, but is, to some extent, necessary in deciding the case now before us.

"About fifty years since, the Legislature undertook 'to regulate the practice of physic and surgery in this State,' and made it penal to do either without being duly licensed for the purpose (3 Greenleaf, 417). To the like effect was the subsequent act of 1801 (1 K. & R., 449).

"These statutes did not, in terms, declare that no compensation should be recovered by an unlicensed practitioner, but they did what was equivalent to such an enactment, for they subjected him to a penalty for the unauthorized and illegal act. But a statute passed in 1806 expressly declared that any person who should commence practice after the first day of September then next, without being duly licensed, should 'forever thereafter be disqualified from collecting any debt or debts incurred by such practice' (4 Web., 538, § 7). The Revised Laws of 1813 contained a similar provision (2 R. L., 222, § 12), as did the Revised Statutes of 1830 (vol. i. 455, § 22). This section of the Revised Statutes also made the unauthorized practice of physic and surgery 'a misdemeanor, punishable by fine or imprisonment, or both.' This was a short-lived clause, for it was repealed by the act of April, 1830, which made the offence penal, not criminal, and which also declared that such penal provisions should 'not be deemed and taken to extend to or debar any person from using or applying, for the benefit of any sick person, any roots, barks, or herbs, the growth or produce of the United States' (Laws 1830, p. 141). This statute was interesting in more than one respect; quackery ceased to be a crime, and if confined to the use of domestic roots, barks, and herbs, it was not even a penal offence. Much had thus been gained, although a complete triumph was not achieved. The empiric, although still unable to compel payment for domestic roots, barks, and herbs, when administered, had only to exact payment in advance, and he stood on safe ground. But this limited indulgence to ignorance and imposture called for redress, and it was attempted to be given by the Act of 1834, which provided that the exception from the penal provisions of the act of 1830 should be confined to such persons as should, *without fee or reward*, use or apply roots, barks, or herbs, the growth or produce of the United States (Laws 1834, p. 72). The next Legislature held this remedy to be worse than the disease, and the Act of 1834 was blotted out in 1835 (Laws of 1835, p. 354). Thus the law on this subject was thrown back to the revised laws, and the Act of April 7, 1830, both which remained in force until 1844, when the Legislature swept away all criminal and penal laws against the unlicensed practice of physic and surgery, and every enactment which prohibited any person from recovering a compensation for services as a physician or surgeon, whether licensed or not (Laws of 1844, p. 406).

"The triumph was now complete, for the Legislature had made every man a doctor, and nostrums of every description and admixture could now be safely prescribed, and payment therefor exacted by authority of law. This is still (1847) the state of the law on this subject, for I believe it has undergone no change since the Act of 1844 was passed. But such was not the law in 1840, when the services in question in this case were rendered. The Act of April, 1830, and the first clause of the twenty-second section of the Revised Statutes already referred to, were then in force. These provisions are consistent with each other. One of them, the Revised Statutes, declares that "every person not authorized by law who, for any fee or reward, shall practise physic or surgery in this State, shall be incapable of recovering by suit any debt arising from such practice." And this was not changed by the Act of April, 1830, which, while it subjected unlicensed practitioners to the payment of penalties, exempted from such penal provisions those who used or applied 'for the benefit of any sick person, any roots, barks, or herbs, the growth or produce of the United States."

"The plaintiff was a botanic physician, and it may be fair to hold upon this return that he used only vegetable remedies of domestic origin. He was, then, not subject to any penalty for prescribing and administering them, but while the Revised Statutes were in force he could not compel payment for his services as an unlicensed physician, whatever remedies might have been prescribed and administered. Such was the law in 1840, when the services were rendered, and as to his case, it was the same in 1845, when the case was tried. The repeal of the previous prohibitory laws by the Act of 1844 had no effect upon cases which arose before that act was passed."

This statute (Laws of 1844, chap. 275, p. 406) was again examined by Daly, Ch. J., in a case in the Court of Common Pleas, between a vocalist, one Emilio Rossi Corsi, as plaintiff, and Max Maretzek, as defendant, in 1855 (4 E. D. Smith's R., 1).

The head-note of the case, or that portion of it which appertains to our present inquiry, is as follows:

"In the absence of special statutes, the law does not exclusively recognize any particular system of medicine or class of medical practitioners."

"The statutory regulations formerly in force in the State of New York, requiring as a condition to the right of recovery for medical services an attendance upon lectures, an examination before a medical board, and a certificate from an organized association, are repealed."

"The repealing act (Session Laws of 1844, chap. 275, p. 406) expressly permits any person to practise physic, subject to punishment, as for a misdemeanor, if convicted of gross ignorance, malpractice, or immoral conduct."

"Medicine is a progressive rather than an exact science; and in determining the legal significance of the word 'physician' or 'doctor,' when used in a contract, the term must be held to mean any person who makes it his regular business to practise physic."

"Accordingly, where an agreement of employment between an opera director and a vocalist provided for forfeiture of a month's salary in case the latter should fail to attend at any stated performance, except in the event of sickness certified to by a doctor, to be appointed by the director, *held*, that the provision was binding upon the artist, although the director appointed a person in the practice of what is known as the homœopathic system of medicine."

In the course of his opinion, Chief Justice Daly has the following to say in regard to the history of the theories and practice of medicine. To be sure this opinion was given a quarter of a century ago, but we are not sure that he does not still hold the same views. He must, certainly, as to its early history. It is interesting, however, as coming from so intelligent and highly respected a source:

"By the terms of the contract the selection of the doctor was left entirely to the defendant, and it was for him to judge of the fitness or capacity of the person to be selected. All that he was required to do, in the fair interpretation of the contract, was to appoint a person, who made it his business to practise physic, and it was wholly immaterial to what school of medicine the person so selected belonged, or whether he belonged to any. The legal signification of the term doctor, when employed as it is in this contract, means simply a practitioner of physic. The system pursued by the practitioner is immaterial. The law has nothing to do with the merits of particular systems. Their relative merit may become the subject of inquiry when the skill or ability of a practitioner, in any given case, is to be passed upon as a matter of fact. But the law does not and cannot supply any positive rules for the interpretation of medical science. It is not one of those certain or exact sciences in which truths become established and fixed, but is essentially progressive in its nature, enlarging with the growth of human experience, and subject to those changes and revolutions incident to any branch of human inquiry, the laws of which are not fully ascertained. The labors of the anatomist, the physiologist, and the chemist, have contributed an immense storehouse of facts; but the manner in which this knowledge is to be applied in the treatment and cure of diseases, has been, and will probably continue to be, open to diversity of opinion. No one system of practice has been uniformly followed, but physicians, from the days of Hippocrates, have been divided into opposing sects and schools. The sects of the Dogmatists and the Empirics divided the ancient world for centuries, until the rise of the Methodics, who, in their turn, gave way to innumerable sects. Theories of practice, believed to be infallible in one age, have been utterly rejected in another. For thirteen centuries Europe yielded to the authority of Galen. He was implicitly followed—his practice strictly pursued. Everything that seemed to conflict with his precepts was rejected; and yet, in the revolutions of medical opinion, the works of this undoubtedly great man were publicly burned by Paracelsus and his disciples; and for centuries following, the medical world was divided between the Galenists and the Chemists, until a complete ascendency over both was obtained by the sect of the Vitalists. This state of things has been occasioned by the circumstance that medical practitioners have often been more given to the formation of theories upon the nature of disease and the mode of its treatment than to that careful observation and patient accumulation of facts by which, in other sciences, the phenomena of nature has been unravelled. I am far from undervaluing the great benefits conferred upon mankind by the study of medicine, and have no wish to minister to any vulgar prejudice against a useful and learned profession, but it is not to be overlooked that, as an art,

it has been characterized in a greater degree by fluctuations of opinion as to its principles and the mode of its practice, than perhaps any other pursuit; that it has been distinguished by the constant promulgation and explosion of theories; that it has alternated between the advancement of new doctrines and the revival of old ones; and that its professors in every age have been noted for the tenacity with which they have clung to opinions, and the unanimity with which they have resisted the introduction of valuable discoveries. They still continue to disagree in respect to the treatment of diseases as old as the human race; and, at the present day, when great advances have been made in all departments of knowledge, a radical and fundamental difference divides the Allopathists from the followers of Hahnemann, to say nothing of those who believe in the sovereign instrumentality of water.

"In fact, nothing comparatively is known of the philosophy of disease. Its eradication or cure, when the result of human agency, is, in the great majority of instances, attributable rather to the careful observation, judgment, and experience of the particular practitioner, than the application of general or established methods available by all. The popular axiom, that 'doctors differ,' is as true now as it ever was, and as long as it continues to be so, it is impossible for the law to recognize any class of practitioners, or the followers of any particular system or method of treatment, as exclusively entitled to be regarded as doctors. In adverting to the conflicting views and differences of opinion that exist and have ever existed in the practice of the healing art, it is not to call in question the value of learned, skilful, and experienced physicians, but merely to show the error of attempting, in the present state of medical science, to recognize, as matter of law, any one system of practice, or of declaring that the practitioner who follows any particular system is a doctor, and that one who pursues a different method is not.*

"The error of the court below consisted in undertaking to do this; in holding that the person appointed by the director was not a doctor, because he practised upon principles of homœopathy, and in assuming, judicially, that a license from some institution or body, or a degree conferred by some medical college, or the authority of some medical society, was necessary before a man could be considered in the law a practitioner of physic. The qualifications of physicians have occasionally been made a matter of statute regulation. To secure a certain amount of preparatory knowledge, laws have been passed requiring an attendance upon medical lectures, an examination before a medical board, and a certificate from organized medical bodies, before an individual was authorized to practise, or at least before he could maintain an action to recover for his services. Such laws formerly existed in this State, but the Legislature, whether wisely or not, thought fit to repeal them by the Act of 1844 (Laws of 1844, p. 406). And since the passage of that act, any person may practise physic in this State, and maintain an action for his services, subject to being punished for a misdemeanor if convicted of gross ignorance, malpractice, or immoral conduct, and with a liability to an action for damages in the event of malpractice. If the plantiff desired a particular kind of physician, he should have stipulated for him; but, having left the selection entirely to the director, the director had a right to appoint an homœopathic physician, or to appoint any individual who made it his regular business to practise physic.

"Judgment reversed."

The Statute of 1844 was again the subject of comment by Mr. Justice Sutherland, in the Court of Appeals, in 1870. A case was brought there on appeal, from the Montgomery Circuit, in 1861, wherein an allopathic physician had called a homœopathic physician a "quack," for which epithet the latter brought an action for libel, and before a jury recovered a verdict for $200. The court, in its unanimous opinion, says: "The legislation of this State, from and including the Act of the 23d March, 1797 (3 Gr., 427), to the Act of May 6, 1844 (Laws 1844, p. 406), had so far and continuously recognized and regulated the practice of the allopathic system or school of medicine (and which may still be called the old and perhaps the ordinary system or school of medicine), as the only legal system or school of medicine, that I question whether any physician or person calling himself, or called by others, a physician, not licensed as an allopathic physician, could, previous to the Act of 1844, have maintained an action against any one for calling him a quack.

"For the statutes concerning the practice of physic and surgery in this State, prior to the Act of 1844, in addition to the Act of 1787, see the Act of 1801 (1 K. & R., 449); the Act of 1806 (4 Web., 538); 2 Rev. Laws of 1813, p. 218; 1 Rev. Stats., 451–456; Act of April 7, 1830, Laws, 1830, p. 141; Act of April 5, 1834, Laws, 1834, p. 72; Act of May 11, 1835, Laws, 1835, p. 354; see also March *v.* Davison (9 Paige R., 585, 586); Bailey *v.* Mogg (4 Denio, 60).

"Since the passage of the Act of 1844, I do not think that it can be said that the laws of this State recognize any particular school or system of medicine as the legal or authorized school or system; for that act, in effect, abolished all previous statutory regulations and restrictions concerning the practice of medicine, and authorized any one without any license, to practise physic and surgery, and to 'prescribe for or administer medicines or specifics to or for the sick,' and to recover for his or her services, at the peril of being sued for malpractice, and if convicted of gross ignorance, malpractice, or immoral conduct, of being punished therefor by fine or imprisonment, or both, as a misdemeanor.

"We cannot avoid taking judicial notice of the fact that homœopathy, as a distinct system or school of medicine, with its professors and physicians, medicines and formulas, treatises and schools of instruction, and with a fair share of intelligent persons for its patrons and patients, has existed in and been diffused through this State, and in and through other States and countries, for some time past; and I do no see why, in this State, since the Act of 1844, the allopathic and the homœopathic physicians have not had, and have not now, equal and the like remedies for slanderous or libellous attacks on their professional reputations or characters.

"In view of the Act of 1844, pretentious ignorance of the system must be regarded as making the quack, and not the system.

"To call a physician, whether homœopathic or

* It may, perhaps, be safely questioned, whether the sister sciences of law and theology present any such history or certainty of opinion as might enable them to arraign the medical profession, and whether the course of human investigation, upon any field of inquiry, is not equally marked by a tenacious adherence to old landmarks, and a gradual adoption of new theories of progress. The opposition encountered by Harvey's discovery of the circulation of the blood, finds its counterpart in every stage of natural science since the persecutions which inaugurated the Copernican system of the universe.—REPORTER.

allopathic, a quack, is in effect charging him with a want of the necessary knowledge and training to practise the system of medicine which he undertakes to practise, and which he holds himself out as having received, by undertaking to practise; and I do not see why it is not now, and has not been since the Act of 1844, just as actionable falsely and maliciously to call a homœopathic physician a quack as to call an allopathic physician a quack.

"There cannot be any doubt, I think, that to falsely and maliciously call either a quack is actionable, and has been since the Act of 1844." . . . .

This review of the statutes and decisions brings us to the condition of the subject as found in the Revised Statutes so-called (1 Rev. Stat., sixth edition, 1109–1122).

In examining these provisions we find that they are a compilation left unrepealed, or so supposed to be, and as amendments and additions from 2 R. L., 220, §§ 12, 20, 21; Laws 1818, p. 192; Laws 1819, p. 308; Laws 1827, p. 178; ch. 123 of Laws 1854; Laws 1851, ch. 116, §§ 3, 4, and they provide as follows:

SECTION 1.—Medical societies shall require physicians and surgeons to apply for admission.

SECTION 2.—If persons notified do not apply, license to be forfeited.

SECTION 3.—Charges may be preferred to the society against members for misconduct, for gross ignorance, or for immoral conduct or habits.

SECTION 4.—If two-thirds of members present at the meeting shall be of opinion that the charges are well founded, a copy of the charges shall be delivered to the district attorney of the county, and a notice thereof to the member accused, who from that time shall be suspended from practice until the determination of such charges.

SECTION 5.—The district attorney shall serve a copy of the charges on the accused and give notice of hearing before the county judges, who shall hear and determine them, and if found true the member accused shall be expelled from the society, and declared incapable of practising; or he may be suspended for a limited period; or he may be acquitted, in which case his suspension from practice shall cease, and he shall be restored to all his former professional rights.

SECTIONS 8–11 provide the qualifications of students.

SECTIONS 13–22 give power to the Regents of the University, under certain conditions, to grant diplomas, conferring the degree of Doctor of Medicine, etc., which degree shall be a license to practise physic and surgery.

SECTIONS 23, 24.—Candidates rejected by censors in one county not to be examined in another, but may appeal to State Society, and persons rejected by State censors shall not be admitted to examination by county censors.

SECTION 25.—No person shall practise physic or surgery unless he shall have received a license or diploma for that purpose from one of the incorporated medical societies in this State; or the degree of Doctor of Medicine from the Regents of the University; or shall have been duly authorized to practise by the laws of some other State or country, and have a diploma from some incorporated college of medicine or legally incorporated medical society in such State or country.

SECTION 26.—No person coming from another country shall practise physic or surgery in this State until he shall have been examined and licensed by the censors of the State Medical Society; and no person coming from another State shall practise physic or surgery in this State until he shall have filed a copy of his diploma in the office of the clerk of the county where he resides, and until he shall have exhibited to the medical society of that county satisfactory testimonials of his qualifications, or shall have been examined and approved by its censors (Laws 1841, chap. 64).

SECTION 27.—No diploma granted by any authority out of this State, to an individual who shall have pursued his studies in any medical school within this State, not incorporated and organized under its laws, shall confer on such individual the right of practising physic or surgery within this State.

SECTION 28.—Every person licensed to practise physic or surgery, or both, shall deposit a copy of the same with the clerk of the county where he resides, who shall file the same in his office, and until such license is so deposited, such person shall be liable to all the penalties provided by law, in the same manner as if he had no license.

SECTION 29.—No person under the age of twenty-one years shall be entitled to practise physic or surgery in this State.

SECTION 30.—The degree of Doctor of Medicine conferred by any college in this State shall not be a license to practise physic or surgery, nor shall any college have or institute a medical faculty to teach the science of medicine in any other place than where the charter locates the college.

From the consequence of disobedience to this provision, Geneva College, The University of the City of New York, the Albany Medical College, Buffalo University, Madison University, St. John's College, Rochester University, New York Medical College, Albany University, New York College of Dental Surgery, People's College, Metropolitan Medical College of the City of New York, Excelsior Medical College in the City of New York, and the American College of Medical Science are respectively, upon certain conditions, excepted. By the law of 1853, chap. 184, § 11, the degree of Doctor of Medicine could be conferred by the trustees of all colleges upon the applicant showing certain required qualifications.

The law of 1844, chap. 275, quoted above, is still in force.

By chap. 746, Laws 1872, the Regents of the University are granted power to appoint one or more boards of examiners in medicine, each board to consist of not less than seven members, who shall be licensed to practise physic and surgery in this State. The examiners are to examine the candidates referred to them for the purpose by the Chancellor of the University in anatomy, physiology, materia medica, pathology, histology, clinical medicine, chemistry, surgery, midwifery, and therapeutics, according to each of the systems of practice represented by the several medical societies of this State, and make a full report thereof to the Chancellor. Any person over twenty-one years of age, of good moral character, and paying not less than twenty-five dollars into the treasury, and who shall adduce satisfactory proofs to the Chancellor that he or she has a competent knowledge of all the branches of learning taught in the common schools of this State, and of the Latin language, may be examined. The Regents, upon certain conditions to be observed, may grant a diploma to the candidate, conferring the degree of Doctor of Medicine, which degree shall be a license to practise physic and surgery.

This is an additional piece of legislation in the same spirit which seems to have governed much that has gone before in this State, the object seeming to be to open as wide as possible the entrance to the practice of medicine. But in view of what had already been done, and the ease with which any competent and proper person could be licensed to practise physic and surgery in New York, and the number of very respectable medical schools throughout the State, whose special business and duty it is to furnish society with the necessary number of custodians of health, well prepared for their business, unless there be some hidden scheme in the belly of the act, which laymen are not expected to discover, we can see no good reason for its passage.

The Statute of 1874, chap. 436, was passed to provide for the censorship by the censors of the medical societies, "of every practitioner of medicine and surgery in this State, *excepting licentiates* or *graduates* of some medical society or chartered school," and by the third section of this act it is declared a misdemeanor for any person to practise medicine or surgery in this State unless authorized so to do by a license or diploma from some chartered school, State Board of Medical Examiners, or medical society, or who shall practice under cover of a medical diploma illegally obtained, and any person found guilty of such a misdemeanor shall, for the first offense, be fined not less than fifty nor more than two hundred dollars, for any subsequent offense not less than one hundred nor more than five hundred dollars, or by imprisonment not less than thirty days, or by both imprisonment and fine; and all such fines shall go into the county treasury of the county bringing such action.

The last piece of legislation to which we arrive in our examination is chap. 513, Laws of 1880, entitled "An Act to regulate the licensing of Physicians and Surgeons."

Section 1 confirms the authorization of physicians to practise who duly conformed to the laws in existence when they were admitted; and such as are authorized by the Regents under chap. 746, Laws of 1872; and forbids all others, unless he is twenty-one years of age, and is authorized by subsequent sections of this act.

Section 2.—Requires all persons lawfully engaged in practise to register in the county clerk's office before the first day of October, 1880; and every other person, before commencing to practise, to register likewise, making oath of his authority, and paying a fee of twenty-five cents.

Section 3.—The penalty for violation of these provisions, or for practising under cover of a diploma illegally obtained, is a misdemeanor, punishable by fine or imprisonment, or both; the fines, when collected, to be paid one-half to the informer and one-half into the county treasury.

Section 4.—Provides the manner in which persons coming from without the State may be licensed to practise here, upon being registered as above.

Section 5.—The Degree of Doctor of Medicine lawfully conferred by any incorporated medical college or university in this State shall be a license to practise, after registration of the person.

Section 6.—Not to apply to medical officers of the United States Army and Navy. "Nor shall it apply to any person who has practised medicine and surgery for ten years last past, and who is now pursuing the study of medicine and surgery in any legally incorporated medical college within this State, and who shall graduate from and receive a diploma within two years from the passage of this act."

This latter provision of the sixth section of this act is the only one over which any person called upon to interpret the statute might long hesitate before defining its meaning. Reading it by itself one is disposed to ask several questions in regard to it, the chief one of which would be, Why was it put there? and, What idea was it intended to express? He might inquire if it is meant to apply to those persons who have been legally or illegally practising medicine for ten years, either without any diploma or license from any medical society or school, or other legal source, or who have just discovered their ignorance and inefficiency and entered some incorporated medical college with a view of graduating in two years with a degree? Do doctors do such things? And if they follow this direction why should they be exempt from registration, after they take their degree, over every other respectable physician in the State? There is nothing in the phrase itself to show that it refers to non-residents more than to residents, to those who have practised here or elsewhere, and the presumption is that it applies to all. I very much doubt, however, whether it be worth while to disturb ourselves very much over it. It is not likely to happen that any quack, charlatan, or impostor, who has escaped arrest and punishment while practising for ten years, or any other person, for that matter, will now enter any medical school for a regular course of study with a view of obtaining a regular degree. If they have got along well enough without it so far, they will hardly let it trouble them for the future. This act is drawn somewhat inartificially, or at least it so now appears, but that may well have arisen from certain amendments introduced subsequent to its original form. But the papers in your issue of October 9 and 23, 1880, respectively, are sufficiently full to satisfy any craving on the part of the profession for further discussion of the legal meaning of the act, until a judicial exposition of it is had from the courts.

This review of all the past legislation in the State upon the subject in hand may prove serviceable in the preparation of any future full and complete act of the Legislature which shall meet the demands of the times. And if it should so prove, the medical profession are welcome to its use.

New York, March 14, 1881.

---

Therapeutic Uses of Tobacco.—Dr. G. M. Christine urges the more extended use of tobacco in the form of poultices. Dr. Christine considers it very efficacious in relieving pain, when poultices of mush or flaxseed are of no avail. To make the poultice the leaves are the best, but segar clippings will answer. The tobacco should be cut up fine, and mixed with flaxseed meal. The poultice is then made in the usual manner, a piece of linen or gauze being placed between it and the body. Care must be taken, of course, that the part of the body to which the poultice is to be applied be not denuded of cuticle.

Disinfection by Heat.—The National Board of Health has had made a floating disinfecting apparatus by means of heat, to be used in connection with the inspection service on the Mississippi River. It is arranged so that the clothing, bedding, etc., of an infected vessel can be subjected to a dry heat of 230° F.

# Progress of Medical Science.

ATROPIA-POISONING SUCCESSFULLY TREATED BY HYPODERMIC INJECTION OF PILOCARPIA.—Professor Purjesz relates, in the *Pester med.-chir. Presse*, Nos. 15, 17, and 18, 1880, the case of a hospital patient, aged nineteen, under treatment for aortic insufficiency and kerato iritis, who drank, with suicidal intent, the contents of a bottle containing atropia in solution, used for his eyes. The quantity of atropia taken was about nine-tenths of a grain. The pupils were dilated to the maximum, the face was pale; respiration frequent, forty to fifty in the minute; pulse 140 to 150. The patient was perfectly unconscious, but sensibility was not lost. Relying on the observation by Lucksinger of the physiological antagonism between atropia and pilocarpia, Dr. Purjesz injected in succession six syringefuls of a one per cent. solution of pilocarpia (about 0.9 grain in each), and repeated the injection at intervals of from five to eight minutes. After the tenth injection the patient began to speak; the pupils were distinctly narrower, and, as the secretion of saliva and sweat had not yet appeared, another injection of nine-tenths of a grain of pilocarpia was made. After this dose the patient gave rational answers, the pulse fell to 80, the pupils regained their normal size, but reacted rather slowly to light, the respiratory movements became normal, the skin moist, and all the symptoms of poisoning by atropia disappeared.—*British Medical Journal*, February 26, 1881.

BEHAVIOR OF FRESH AND DEAD TISSUES IMPLANTED IN SEROUS CAVITIES.—Rosenberg (*Archiv für klin. Chir.*, vol. xxv., p. 721) has performed a series of experiments on animals, in order to determine the fate of bits of tissue inserted into the organism under antiseptic precautions. Pieces of muscle, skin, and other tissues were taken from healthy animals, and after immersion in alcohol deposited in the peritoneal cavity of dogs or rabbits. Entire rabbits' kidneys were also put into the abdomen of dogs. Of forty animals experimented upon, only seven died of peritonitis. It was ascertained that pieces of tissue may thus heal up either entirely without, or with only very slight reaction. After some time the substances disappeared without leaving the slightest trace. Absorption took place by three principal methods:

*First.*—The implanted tissue was surrounded during the first three or four days by a capsule, which gradually increased in thickness. Through this corpuscles emigrated and destroyed it. At a later period pus, with remnants of tissue floating in it, could be found. Giant cells were also often seen between the capsule and tissue.

*Second.*—This mode of healing was less frequently observed, and only in pieces of small size. After six days the piece of tissue gradually coalesced with its neighbors, and a closely adherent capsule was formed; through this the implanted substance received its nourishment. Its structure was retained for a long time. In the case of muscle, the transverse striation gradually disappeared, then the longitudinal, and lastly the sarcolemma was destroyed. With dead tissue, the cells migrated between the muscular fibres, developed into connective tissue, and finally caused obliteration of the foreign substance.

*Third.*—The peripheral layers were formed as in the second variety, but pus was found at the centre, in accordance with the first process. The location of the tissue was not a matter of indifference. The large omentum was found the most favorable place for resorption, while substances deposited in the neighborhood of the peritoneal wound invariably produced suppuration.—*Centralblatt für Gynäkologie*, April 2, 1881.

SUCCESSFUL TREATMENT OF ACUTE PHTHISIS BY THE CONTINUOUS TOPICAL MEDICATION OF THE LUNGS.—Dr. G. Hunter Mackenzie records in detail (*Lancet*, May 14, 1881) the successful treatment of a case of acute phthisis by causing the patient to respire as continuously as possible an "antiseptic" atmosphere. The result obtained would appear to bear out the experiments of Schüler of Griefswald, who found that animals rendered artificially tuberculous were cured by being made to inhale creosote water for lengthened periods. The patient was a young man, aged eighteen, who complained of general weakness, cough, and emaciation. Two brothers had died of phthisis, and there was a history of the same disease in his maternal relations. Beyond a slight roughening of the respiratory sounds, and prolonged expiration, there was nothing to be detected in the lungs. He was ordered cod-liver oil with hypophosphites, abundance of milk, and residence in the country; but in three months he grew rapidly worse. The fever increased, an evening temperature of 103° being recorded, with a corresponding quick pulse, shallow and hurried respiration, lips coated with sordes, thirst, and lividity of the extremities. At this time the lungs gave undoubted signs of disease, there was marked dulness over the upper third of the left lung anteriorly, with copious fine crepitation, racking cough, occasionally bloody sputum, severe night-sweats, and loss of hair. The treatment pursued in the first instance failed to relieve, when the system of topical medication was commenced with the following results: 1, slight fall of temperature; 2, great diminution of the cough, with complete cessation of the muco-purulent sputum; 3, marked improvement in the appetite and general strength; 4, gradual abolition of the night-sweats; 5, improvement in the physical condition of the lungs. Dr. Mackenzie believes that the success obtained in this case was owing to the particular method of treatment employed. For this purpose he has used various volatile antiseptics such as creosote, carbolic acid, and thymol; the latter he has discarded as being too irritating and inefficient. Carbolic acid seems to be absorbed, for it has been detected freely in the urine; no trace of creosote, on the other hand, has been found in the urinary excretion after its use for several consecutive days. As absorption of the particular drug employed is not deemed necessary, and therefore not to be desired, he now uses creosote only, either pure or dissolved in one to three parts of rectified spirit. Whether the success so far attained is due to the antidotal action of creosote and carbolic acid on a specific tubercular neoplasm, or to their action as preventives of septic poisoning from the local centres in the lungs, it is certain that their continuous, steady use in the manner described has a decidedly curative action in acute phthisis, and is therefore worthy of an extended trial.

DR. HESCHL, who succeeded Rokitansky a few years ago as Professor of Pathological Anatomy at Vienna, died on May 27th, in the fifty-seventh year of his age.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 9, 1881.

## THE WOUNDED PRESIDENT.

THE various press bulletins which have announced the condition of the wounded President have not given, to the medical mind at least, a very intelligible idea of the precise nature and extent of the injuries inflicted. Neither have the symptoms been given with sufficient detail to enable a reasonably tenable opinion to be formed concerning the probable issue. Of course each medical man has weighed the probabilities as best he could from the data furnished. It is fair to suppose that a grave prognosis has been warrantable from the first, and that even the present report of an improvement in the symptoms must be accepted with reasonable misgivings as to the final result.

In order to appreciate the full significance of the situation, it is quite necessary that the case be studied in its surgical bearings, that the various facts in its history be carefully noted and their relative importance duly considered. We have taken great pains to obtain an authoritative account of the important facts bearing upon the character of the injury inflicted, and present them to our readers, not only for the special interest they may have in connection with the distinguished victim, but for their intrinsic importance in a strictly surgical point of view.

President Garfield, while in the act of walking in the depot at Washington, D. C., was shot at 9.20 A.M. July 2d. The ball entered the right side, about four inches from the median line of the spine, and on a level with the tenth intercostal space, penetrating the body. This wound was the result of the second shot, the first shot having merely penetrated the left side of the President's travelling coat, The would-be assassin was, at the time of firing the shot, six feet behind his victim and to the right. The weapon was a large-sized revolver, known as the English bulldog, and carrying a No. 42 conical ball, which is equal in size to that used in the ordinary navy pistol. At the time of firing, the assassin rested his pistol on his right forearm, the muzzle being inclined slightly downward.

After the first shot was fired the President turned toward the left, and almost immediately after the second shot sank forward on his knees. He was at once raised from his position, when he vomited.

Within five minutes after the shooting Dr. Smith Townsend was in attendance. He found the patient suffering severely from shock, and administered aromatic spirits of ammonia and brandy. Drs. D. W. Bliss and Dr. Purvis arrived soon after. The former gentleman then took formal charge of the case. Surgeon J. J. Woodward, of the Army, called, when a consultation was held, with the result of removing the patient to the White House. This was done after a repetition of the stimulants. When the ambulance arrived at the White House, shortly after 10 A.M., the patient was still suffering from shock and complained of pain and tingling in both legs and both feet. An hypodermic injection of morphine was administered (one-eighth of a grain) and stimulants were continued.

In the course of the next four hours the President's condition was critical and fears of internal hemorrhage were entertained. No examination of the wound was considered warrantable. The nausea and vomiting which had been troublesome during this period became more so at 3 P.M., and what was previously a partial reaction became a condition of relapsed shock, indicating internal hemorrhage. A consultation was held at this time by the attending physician, Dr. Bliss, with Surgeon-General Barnes, U. S. Army, Surgeon-General Philip S. Wales, U. S. Navy, Surgeons J. J. Woodward and Norris, U. S. Army, and Drs. Robert Reyburn, Townsend, Patterson, Purvis, and Lincoln, of Washington. It was then concluded that the patient was not in a condition to allow any attempt at finding the course of the ball; stimulants were continued, and also morphine in sufficient amount to control the distressing pain and tingling in the lower extremities. An examination of the region of the liver revealed an increased area of dulness extending parallel to the lower margin of the organ and two inches below the free border of the ribs. The margin of dulness was lost in the mass of fat posteriorly.

A careful examination of the chest revealed nothing abnormal save a comparatively slight want of expansion of the right side on inspiration. This was in all probability caused by the pain from the wound. The pulse was 102, temperature 96° F. The urine had been voided during the morning, was free from blood, and was healthy in appearance.

At 4.30 P.M. the patient was comparatively easy, and was under the influence of morphine.

In the evening, at 7 o'clock, another consultation was held. Reaction had then taken place, and an examination of the wound was determined upon.

The point of entrance was, as previously stated, nearly four inches from the spine, in the tenth intercostal space. The margins of the orifice were sharply defined, and there was no grazing of the skin in any direction, showing that the missile must have entered at right angles with the surface. The hole itself was small as compared with the size of the ball, being barely large enough to admit the introduction of the little finger.

An examination of the wound was made by Drs. Bliss and Wales. The latter was able to insert his little finger to its full length between the tenth and eleventh ribs, and in a direction forward, downward, and slightly inward. It was his opinion, from the feel of the parts, that the ball had penetrated the substance of the liver and had passed through it into the abdominal cavity. In confirmation of this view there was, after the examination, a venous hemorrhage from the wound, estimated to be equal to half a pint in quantity. It was also discovered during the examination that the lower margin of the tenth rib had been struck and fractured. The existence of the painful sensations in the lower extremities gave rise to the suspicion that the spine had been injured, but such could not be confirmed by the direction the ball was supposed to have taken.

10.20 P.M.—Reaction was fairly established, pulse and temperature normal. The stomach was irritable and there was considerable nausea. Constant complaint was made of pains in the lower extremities. The patient having retention of urine, probably as the result of the administration of morphine, was relieved by the catheter.

The diet was milk and lime-water, together with cracked ice.

After passing a comparatively comfortable night, the pulse was found at 6 A.M. of Sunday, July 3d, to be 116; respirations, 18; and temperature normal. During this day the patient remained quite easy, being still under the influence of morphine, and complaining only occasionally of the tingling sensations in the feet. The pulse ranged from 108 to 114 and temperature remained normal until 10.30 P.M., when the former rose to 120, the temperature to 100° F., and the respirations to 20 per minute. There was complaint of increased pain in the feet, and the patient was nauseated and restless. Some tympanites began to show itself at this time. In the course of the next two hours, shortly after midnight of Sunday, the pulse was reduced to 112, temperature to 99.8° F., and respirations to 20 per minute. The pain in the feet also became less marked.

On Sunday afternoon Dr. Frank H. Hamilton, of New York, and Dr. D. Hayes Agnew, of Philadelphia, were called in consultation, and arrived on the morning of July 4th.

A consultation was held, July 4th, 7 A.M., at which were present Drs. D. W. Bliss, J. K. Barnes, J. J. Woodward, and Robert Reyburn, of Washington; Dr. Frank H. Hamilton, of New York; and Dr. D. Hayes Agnew, of Philadelphia. The pulse was then 108, temperature 99.4° F., respirations 19. There was some tympanites present, but there was no pain on pressure nor rigidity of the abdominal walls. It was concluded that the tympanitic condition was in a great measure due to the morphine taken, as was also the more or less persistent nausea. Up to this time the patient had been taking by hypodermic injection a quarter of a grain of morphine every eight hours. An examination of the wound confirmed the diagnosis of Dr. Bliss and previous consultants as to the general direction of the missile, but no positive conclusions were arrived at as to the position of the ball or the extent of injury it had inflicted. It was discovered, however, that in addition to the other injuries there was a splintering of the upper margin of the eleventh rib. The general impression appeared to be that the ball had perforated the lower margin of the right lobe of the liver, and had escaped into the abdominal cavity.

No evidence of its probable location could be made out. The area of dulness around the liver had not increased since first noticed, and there was but slight tenderness on pressure over the part. There had been no movement of the bowels since the injury, but during the consultation the patient had occasional desires in that direction. It was concluded best to allow Nature to take her course in this matter, and no medication was advised to assist her. The patient was perfectly rational, and conversed with Prof. Hamilton on matters unconnected with the shooting. The wound itself looked well, and showed no undue amount of inflammatory action. The result of the consultation was a general endorsement of the treatment pursued, with a recommendation to decrease the dose of morphine from one-quarter to one-eighth of a grain every eight hours. The particular reason for this being that the pains in the feet had disappeared, and in a general way there was no further reason for the use of the drug in such doses. It was also agreed to give the nourishment more frequently and in small quantity.

At 12.30 P.M., July 4th, there was but little change in the condition of the President. Slight pain in the feet was complained of, and there was occasional and slight vomiting. The pulse was 110, temperature 100° F., and respirations 24.

5.15 P.M.—A small quantity of chicken broth was taken and retained.

7.35 P.M.—Pain in the feet still present to a slight degree. Tympanites more noticeable. Pulse 126, temperature 101.9°, and respirations 24.

10 P.M.—No vomiting for past two hours. Pulse 124, temperature 101° F., and respirations 24. At midnight the temperature and pulse had fallen, and he was sleeping quietly. During the evening

he had a full and natural evacuation from the bowels.

July 5th, 8.30 A.M. – The patient passed a comfortable night. No vomiting since last evening at 8 o'clock. Less tympanites and no abdominal tenderness except in the hepatic region. Pulse 114, temperature 100.5° F., and respirations 24. Only one-half a grain of morphine had been administered during the previous twenty-four hours.

At 4.15 P.M. the pulse had fallen to 104, and the patient was resting quietly. 8.30 P.M., pulse was 106, temperature 100.9° F., and respirations 24.

July 6th.—The patient passed a comfortable day, and his general condition remains favorable. Thus, at the time of going to press, the outlook of the case is reasonably promising, although, for obvious reasons, the prognosis is as yet necessarily quite uncertain.

In looking over the general history of the case it is fair to conclude that there is room for a great deal of doubt not only regarding the locality of the missile, but its precise direction. By the system of exclusion we may conclude that neither the lung, kidney, nor portions of the intestines are wounded. It is a legitimate assumption that no large vessel was injured, as the internal hemorrhage was comparatively inconsiderable. The introduction of intelligent fingers into the wound proved that the abdominal cavity was entered. But the penetration to the length of the little finger does not allow of much exploration of a cavity which must be reached in the situation of the wound through the thickness of adipose tissue and muscle of a patient markedly obese and weighing upward of two hundred and twenty pounds.

It does not seem possible to distinguish under the circumstances the tissue of the liver from that of the surrounding organs. It seems proper to assume that the liver has been entered, inasmuch as it is directly in the way of a ball penetrating between the tenth and eleventh ribs and taking a general forward direction. The upper margin of the right kidney is considerably below this point, as is even the upper margin of the right suprarenal capsule. Neither of these organs would be in danger unless the missile had been deflected almost directly downward after its entrance. But everything so far proves that neither of these organs have been touched. Another point in favor of wound of the liver is the venous oozing after the first exploration with the finger. This might be considered more significant of an injury to this organ than the internal hemorrhage, although the limitation of the latter to the hepatic region deserves prominent recognition in such a connection. It is somewhat difficult to reconcile the statements that the tenth rib was fractured, as if possibly struck by the ball, and that the upper margin of the eleventh rib was also splintered. The ball was certainly not large enough to touch both points at once on its entrance. If it struck and glanced and entered the liver at all, it must have been lodged in that organ. Under such circumstances it would be quite as likely to enter the substance of any of the tissues in the neighborhood.

But the greatest difficulty has been to explain the reason for the tingling sensations following the injury and their markedly persistent character. Of course the first idea that suggests itself is that the spine had been in some way injured. But the ball did not seemingly take such a direction. In the absence of any other plausible theory it would seem that these nervous symptoms were purely reflex, either from injury to some portion of the lumbar plexus or to some of the filaments of the great splanchnic nerve. We have reason to believe that the consultants were more inclined to such an explanation than to any other that had been offered. If such an assumption is correct there can hardly be a doubt that the missile must have perforated that portion of the liver intervening.

At present it does not matter, so far as the general symptoms are concerned, what is the precise locality of the ball. The patient is doing well and appears to have tided over the immediate dangers of the wound. Its after-effects, in the shape of possible secondary hemorrhage, abscess, sloughing, and the usual pathological processes attending gunshot wounds in that region, must, however, be viewed with the gravest anxiety. But we are privileged to hope for the best. This we have good reason for doing, considering the strong vital powers of the illustrious patient, and the skilful and judicious treatment he has received from the first moment of his injury.

If there is any criticism to be offered from a medical point of view, it is that there were too many physicians in attendance during the first twenty-four hours. Not that there was any disagreement as to the plan of treatment; but there is always danger to the patient when too many medical heads are put together. Sir James Paget is reported to have said that he considered himself fortunate to recover after six doctors had been in attendance upon him, and we know of another surgeon who survived the continued consultations of twelve of his confrères; but such cases are notable chiefly for their rarity. Fortunately, in the President's case, the difficulty was promptly met, and with the least possible discourtesy to the parties directly concerned.

It was certainly a wise forethought on the part of those who had charge of this important case to avail themselves of outside talent in their consultations. The selection of Drs. Frank H. Hamilton and D. Hayes Agnew as consultants was eminently wise and proper. No more representative men could have been selected from any part of the United States, and no choice could have been made more satisfactory to the profession or to the country at large.

## Reviews and Notices of Books.

MR. PERKINS' DAUGHTER. By the MARCHIONESS CLARA LANZA. New York: G. P. Putnam's Sons. 1881.

THE novel before us has a claim upon medical attention because a certain curious pathological condition, characterized by double-consciousness, is worked into the plot.

Mr. Perkins' daughter, though the heroine of the book, is not the one that becomes subject to this interesting morbid state. She is the daughter of a Kansas millionnaire, and has herself been brought up in New York, and gradually develops into an interesting heroine. She falls in love with one young man, and, upon his proving unfaithful, at once discovers that she has been in love all the time with another, whom she very soon marries. There is introduced into the story, meanwhile, a German fraülein, of lovely person and highly emotional temperament. This latter lady falls in love with Miss Perkins' first lover. Upon hearing that he is engaged, she falls into a trance-coma. From this she gradually emerges, but appears considerably changed in her mental condition. Her loveliness of person and disposition, however, continue unchanged, and she manages to turn the affections of Miss Perkins' *fiancée* from that young lady to herself. This inconstant hero is a very conceited American youth, who is wealthy, scientific, and free-thinking. He abhors the bible, but is never without a copy of "Evangeline." The sweetness and submissive devotion of the entranced fraülein wins his already plighted heart, and he gets released from Miss Perkins. An eminent physician has declared that the fraülein's condition is an abnormal one, and that she does not know what she is about. But the young man knows better, and the two become engaged. Shortly after this pleasant consummation, the young lady is restored to her normal condition, and declares that she knows nothing of her life subsequent to the event which threw her into the trance. Her lover receives his *congé*; he has lost both young ladies and he takes the steamer at once for America.

The fact that there does occasionally exist mental disturbances in which the person lives another kind of conscious life is well established. Indeed a similar condition may be produced temporarily in many trance subjects. In actual life, however, it would be impossible for such a condition not to be recognized. The most infatuated lover could not fail to see the narrowed range and lack of spontaneity in the mental life of the subject. The occurrence woven into this story is an utterly impossible one in its details. And there is perhaps a certain amount of danger in relating such incidents as probable to the general public. Still, we must admit that the facts of pathology are very ingeniously utilized, and are stated with sufficient accuracy for a work of fiction.

Regarding the work as a whole, we should say that it had rather more of merit than the average summer novel.

The author has the courage and skill to draw an imperfect hero, and also to make the incidents of the story change and develop the character of the heroine. We should warn the reader that the first half of the book is decidedly dull; the descriptions given are only tolerable; the conversations are common-place, and the characters have not yet developed anything but what rather repels than excites the sympathy. Much more vigor is displayed in the latter part of the narrative.

A TREATISE ON THE CONTINUED FEVERS. By JAMES C. WILSON, M.D., with an Introduction by J. M. DA COSTA, M.D. New York: William Wood & Co. 1881. Wood's Library of Standard Medical Authors.

THIS work contains chapters upon simple continued fevers, influenza, cerebro-spinal fever, enteric typhus, and relapsing fever, and dengue. The merits of the book are that it presents these subjects quite fully and clearly, yet not with burdensome elaboration. Though the facts recorded have been industriously compiled from all sources, yet the book withal has something of an American character, especially in the matter of history, symptomatology, and treatment.

On the other hand we have looked in vain for anything especially new in it. The author has been chary of giving his own views, experiences, or investigations, if any such he has made, and the work consequently lacks the stamp of individuality. We should have been glad to have found in it, also, something in regard to the pathology of fever.

However, the treatise is an interestng one, and will be found very useful, especially to American practitioners.

A MEDICAL FORMULARY, based on the United States and British Pharmacopœias, together with numerous French, German, and unofficinal preparations. By LAURENCE JOHNSON, A.M., M.D. New York: William Wood & Co. 1881. Wood's Library of Standard Medical Authors.

THE design of this work, the author states, is to present, in a manner convenient for ready reference, the drugs and preparations in common use, together with formulæ illustrating the manner in which they are combined. Besides the regular Pharmacopœias, various hospital formularies have been drawn upon, also the note-books of some prominent physicians of this city. Much labor has evidently been expended by the author, and the book will no doubt, be found a convenient one.

---

A BIOLOGICAL COURSE AT PRINCETON COLLEGE.—Princeton College is to have a post-graduate course in biology, the step having been taken with the hearty co-operation of President McCosh and several members of the Board of Trustees. It will be established in connection with the Geological and Zoological Museums. The avowed objects of this course are to foster a spirit of original research and to qualify advanced students to become teachers. A course of lectures is proposed in which prominent part will be taken by Profs. Arnold, Guyot, George Macloskie, LL.D., Henry B. Cornwall, A.M., E.M., W. E. D. Scott, B.S., and others equally eminent. The courses leading to a degree are open to graduates of colleges and recognized medical schools; other students may attend the lectures and laboratory work, but will not be eligible for a degree.

AT THE U. S. MARINE HOSPITAL SERVICE EXAMINATIONS, recently held in Washington, there were somewhat over a dozen applicants. All failed to pass, however. The next examination will be held in the coming fall.

# Reports of Societies.

## NEW HAMPSHIRE MEDICAL SOCIETY.

*Ninety-first Annual Meeting, held in Concord, June 21st and 22d.*

It was a large and enthusiastic meeting for a small State, there being one hundred and twenty-five members present, and delegates from Massachusetts and Vermont.

The meeting was opened at 11 A.M., the president, Dr. G. P. Conn, occupying the chair, and for an hour the society was principally engaged with routine business, and in listening to the report of the council, which met the evening previous, and attended to all the new business, and to the applications for membership. Their report was accepted, and sixteen new members were elected upon their recommendation, who appeared and were welcomed into the ranks of the society.

At twelve o'clock the president read his annual address, a paper that is required of the presiding officer by the organization of the association.

After making a few suggestions as to the appointments and management of the society, Dr. Conn devoted about thirty minutes to the department of State medicine. He commenced by defining the term, "as being the care the State may reasonably be expected to exercise over the life and health of individuals; to investigate into the causes of epidemics and other disease, in order that each citizen may not only have as long a life as nature would give him, but likewise as healthy a life as possible."

He remarked that the term State medicine was of recent origin, but the idea was not a modern innovation, and showed that ancient history informed us that sanitation was once considered an important factor in the prosperity of the Greeks and Romans, and that it was in consequence of their observance of hygienic rules and regulations that they were accorded that dominant position among all the nations of the world, and that when they failed to recognize State medicine came the decline of their great power, and sanitation became one of the lost arts, filth and pestilence prevailed, and crime and pauperism took the place of good order, health, and prosperity. "Nemesis held the sceptre and Momus was her chief executive officer."

"The laws of health were disregarded and, consequently, each succeeding generation became a striking illustration of retrograde civilization." "The doctrine of predestination, as promulgated by St. Augustine, was seized upon by a people made fanatical by ignorance and superstition and was deemed a sufficient explanation of all that was transpiring, and the measureless waste of human life was considered an illustration of the principles of foreordination."

The speaker referred to what had been done in this country since the establishing of the first board of health in Massachusetts, in 1869, the interest of the profession in the National Board, the position accorded to the subject by the American Medical Association giving it a section, and to the fact that the people were year by year becoming more and more interested in investigating into the causes of disease, and adopting measures that offer any hope of preventing sickness.

He said: "It is but natural that the public should look to us, as representatives of the profession of medicine, to point out the way, and become the leaders of public opinion in a matter that our education should fit us to be the advance guard. Yet it is a humiliating fact that less than half a dozen of our medical colleges have given it the dignity of a professor's chair, or even refer to it as being of sufficient importance to be included in their curriculum of study.

New Hampshire has always been considered a healthy State in which to live, and that there need be no apprehension of epidemic and infectious disease, yet it was shown that near the close of the last century an epidemic of malignant sore throat prevailed in the eastern section of the State that from all accounts must have been much the same disease as the diphtheria of the present day; that typhus and spotted fevers prevailed about 1830; in 1843 erysipelas, in a malignant form, swept down the valley of the Connecticut from its source to tide-water; in 1855 a malignant form of dysentery was alarmingly prevalent in the interior, and "there is hardly one present but can recall one or more towns in which diphtheria has not been epidemic within the past twenty years."

The speaker then commented upon the care the State was expected to exercise over dumb animals, and said, "when an epidemic occurs among the cattle that are scattered over our hillsides, the governor and council are at once petitioned to afford such relief as may be possible by instituting an investigation into the causes of the disease, and preventing its contaminating influence upon other herds.

"This was done soon after 1850, and again during the winter of 1879–80, when an epidemic of small proportions appeared in a fine herd of cattle in the town of Haverhill, when the governor was importuned by the owner and others for aid as *provided by the statute.*" A commission was appointed, who attended to their duty faithfully, when it was found that less than a dozen of the herd were affected, some five or six died or were killed during the investigation, when it was concluded that a little more intelligent sanitary care of the cattle and their surroundings would have prevented the disease, yet the owner has since asked the State to pay him for the cattle.

The speaker claimed that it was but justice toward the agriculturalist to make this investigation, but said that it would appear more consistent for the State to exercise the same care over the human family that it did toward the brute, and said "that at the same time this investigation was in progress in the same county there was an epidemic of diphtheria prevailing, where, in less than one month, and in a radius of less than six miles, there were twenty-eight cases, with seventeen deaths," yet there was no investigation by State authority. After commenting on the fact that a herd of cattle represent a pecuniary value, and as such claimed protection, it was shown that the State would not prosper without the capital invested in the physical force of its inhabitants; and thus representing a value they were entitled to the protecting influence of State power. He claimed that it was the duty of the State to enact legislation to prevent people from living in unhealthy houses, using polluted water, sophisticated drugs and food, as it was to pass laws to suppress intemperance or prevent crime, and as illustrating the dangers of the one compared with the other asked the society if they ever knew of seventeen out of twenty-eight persons addicted to intemperance to die in twenty days? In closing he urged every mem-

ber to labor earnestly in securing the passage of an act to establish a State board of health.

The report on surgery by DR. A. H. CROSBY, besides a review of the progress made during the year, contained the reports of several interesting cases.

DR. JONES, of Portsmouth, read a paper on "Nihilism in Medicine," in which he claimed that conservatism and infinitesimalism were equally culpable in destroying faith in the science of medicine, and that a more hopeful view should be taken.

DR. FELT, of Hillsboro, advocated, in a well-written paper, hypodermic medication, and DR. PARSONS, of Portsmouth, read an able paper on "Puerperal Convulsions." PROF. FROST, of Hanover, gave a short paper on "The Etiology of Typhoid Fever," and DR. KIMBALL an essay on "Conservatism in the Treatment of Certain Forms of Acute Disease."

The Committee on Necrology reported at the evening session.

On Wednesday the papers and cases were discussed, and the following officers elected:

*President*, Dr. H. B. Fowler, Bristol; *Vice-President*, Dr. A. H. Crosby, Concord; *Treasurer*, Dr. D. S. Adams, Manchester; *Secretary*, Dr. G. P. Conn, Concord; with a Council of twenty and a Board of Censors of ten members, and the society adjourned to meet in Concord on the third Tuesday in June, 1882.

## NEW YORK NEUROLOGICAL SOCIETY.

*Stated Meeting, May* 3, 1881.

DR. T. A. MCBRIDE, PRESIDENT, IN THE CHAIR.

DR R. W. AMIDON presented some specimens illustrating the

### PATHOLOGICAL ANATOMY OF CHOREA IN THE DOG.

The speaker said that the subject of chorea in the dog was first investigated by Drs. Gowers and Sankey, in an article entitled "Pathological Anatomy of Canine Chorea." They had two cases of chorea, having symptoms resembling chorea electrica. These observers found very grave lesions in the cord and medulla oblongata, but no lesion in the brain. The lesions in the cord were quite diverse: they consisted in infiltration in various regions, particularly in the lateral parts of the cord. There were also areas of disintegration, proliferation of neuroglia cells, and vacuoles in the motor cells of the anterior horns, which have more recently been noted as appearing in some cases of myelitis. They also assert that the motor cells of the spinal cord are excessively granular, and that the cells of Purkinje are also very granular. The lesions in these two cases did not tally very well, and it is rather hard to attribute the symptoms, which they mention, to the lesions found *post-mortem*. They were very serious lesions for a disease apparently so mild as this one.

Two years ago Dr. James J. Putnam had written an article in the Boston *Medical and Surgical Journal*, giving an account of a very minute examination of two cases of chorea in cats, in which he found no lesions at all.

The speaker said that he had had the good fortune to become the possessor of the entire spinal cord of a dog that had had chorea in the hind legs. This specimen was given him by Prof. Charcot. The history was that of typical chorea of the hinder extremities. The animal had been killed in such a way as to avoid any congestion of the spinal cord. The only lesion found upon examination was a complete filling of the central canal with an amorphous matter that stains very readily with carmine, and there is also an exudation in the perivascular spaces, particularly in those of the gray commissure and anterior horns. (Specimens illustrating these lesions were shown.) It was shown that for most of the extent of the central canal the lining epithelial cells were desquamated and thrown off.

In the discussion that followed, DR. L. C. GRAY said that, interesting as were these specimens, they did not seem to throw much light on the subject of the pathology of chorea.

DR. E. C. SEGUIN said that he was doubtful of the existence of any organic changes in chorea. He believed that it was a disorder of the cerebrum, and not of the spinal cord.

DR. MARY PUTNAM-JACOBI said that an article had recently appeared by Arndt, entitled "Chorea as a Psycosis." She took the view which seemed to her the correct one: that psychical changes always accompany or form part of chorea in children. There was almost always a marked change and impairment in their intelligence.

DR. SPITZKA inquired on what ground it was asserted that the disease which the dog had was chorea.

DR. AMIDON said that he had been told by Charcot that the case was a typical one of chorea. He said, also, referring to the theory of a cerebral origin of the disease, that, in one of the cases reported by Gowers, the spinal cord had been cut just below the medulla, without producing any effect on the choreic movements.

DR. SPITZKA thought that there were two distinct diseases in the dog to which the name chorea was generally given. One of these, and the rarer, was that known as genuine chorea; the other was one that might follow organic changes, such as paraplegia. True chorea he did not believe could be limited to the hind legs. In true chorea, there is no organic lesion. He did not think that there was any cerebral disturbance in chorea in children. The effects observed were due, he thought, to want of coordination in, or twitching of, the muscles. This might mislead the observer, unless a careful study of the symptoms was made.

In this opinion he was strongly opposed by Drs. Jacobi, Seguin, and others.

DR. SEGUIN presented a case of

### INTRACRANIAL TUMOR.

The patient was a man, thirty years of age. About six years ago he had begun to have convulsions. At the same time, he noticed a prominence appearing on the top of his head.

The convulsions appeared at intervals of four or five weeks. They were at first unilateral, attacking the foot first, then the arm, after which the patient lost consciousness, and the spasms became general. He could sometimes tell about half an hour beforehand when the attacks were coming on. He usually vomited during or after the attack. He had no other bad symptoms; no nausea or headache; and his eyesight was good.

Examination of the patient's head showed a remarkable development on the top of the cranium. There was evidently an intracranial tumor there, nearly as large as the two fists. It was situated in the median line. Its growth had separated the bones, and the open sutures and line of demarkation of the tumor could be felt. The measurements of

the tumor and cranium were given, and showed a remarkable increase in the vertical diameter of the head. There was evidently a tumor pressing down upon the brain; the symptoms were in part what might be expected from its situation. Examination of the eye showed neuro-retinitis. The patient's vision, however, as stated, was not impaired as yet. There was slight loss of power on both sides of the body, but more marked on the right side.

The tumor was important in connection with the doctrine of localization. It pressed upon the centres for motion in the arm and leg, parts whose muscular power was manifestly affected.

The patient had been put upon iodide and bromide of potassium and chloral. He had denied syphilis, but had improved under treatment.

Some of the few other similar cases that had been reported were referred to by the speaker, and discussed.

## Correspondence.

### CONCERNING THE CASE OF MICROCEPHALUS.

To the Editor of The Medical Record.

Sir—The following facts seem to have escaped the scrutiny of the author of a paper entitled "Case of Microcephalus," appearing in the Record of June 11th. 1st, that a persistence and prolongation of the transverse occipital sulcus has been recorded by Sander with a lunatic, by Meynert with a sane man, and by myself in the case of an imbecile; 2d, that these cases of the so-called "Affenspalte" do not represent reversions to, nor strictly correspond to the simian type; 3d, that the anomaly of the fissura calcarina noted has been observed by Parker in the case of negroes; 4th, that the asymmetry observed in the disposition of the gyri of the brain described can hardly be interpreted as a tendency to "return to that type . . . . that constitutes such an important characteristic of the higher organization," for in the case of most microcephali studied there was found not only a simple defect, but also great irregularity in development. In fact, atypical asymmetry is one of the frequent and most marked features of idiotic and imbecile brains. The asymmetry of the microcephalic brain should be rather interpreted as an evidence that all cases of insanity and mental defect of the constitutional kind, from that of the plausible systematic delusional lunatic to the non-viable microcephalus belong to one great teratological group.

It does not appear from the experience of those who have confined a large number of women, and have had an opportunity of watching the development of the offspring that there is any such relation between the position of a child *in utero* or *in* space and the development of its brain, such as Tager is quoted in the paper referred to to claim. It seems to me that the constitutional tendency on the part of the mother to miscarry may offer a more satisfactory etiological solution of the problem than the one suggested. With such a tendency, the fact has been frequently observed that such children as are born are imperfectly developed in some one or other respect, while where from disease or other cause the mother has been compelled to occupy the recumbent posture during the greater and especially the latter part of pregnancy, no cerebral defect has been noted to occur with that relative constancy which we should expect if any theory based on the law of gravity were a correct one. On the contrary, there are not a few cases on record where a fracture or other surgical injury happening to the mother has affected the child, not in its nervous development, but in some other respect, although the recumbent position was necessarily maintained.

The observations of Luys, quoted in the paper mentioned, are very imperfect, due regard not being paid to the fact that the nerve-cells of the infant do not show that richness of processes found in the adult. It is difficult to see how there could be an "increase in the neuroglia" in the case published in the Record, if the ganglionic elements were normal in number, size, and arrangement—*non bis in idem*. In such cases I have found the barren layer of the cortex relatively thicker than in health, and the cells more sparsely scattered.

There certainly is a connection between vascular anomalies and defects in cerebral development in a considerable proportion of cases, as witness the excellently described one of Muhr. Dareste has shown that deformities bearing on this question can be artificially produced, and the weight of evidence seems to be in favor of assigning such monstrosities to a defect of the energy of epiblast development, with a resulting preponderance of the connective tissue forming mesoblast. Yours, etc.,

E. C. Spitzka.

New York, June 28, 1881.

### A NEW TREATMENT FOR EPITHELIOMA.

To the Editor of The Medical Record.

Dear Sir: In the spring of 1876, Mr. C—— of this place, a shoemaker at that time, seventy-five years of age, noticed the appearance of a growth upon his left temple. I first saw it in the following September, when it appeared as a well-defined epithelioma. Several of the local physicians examined it individually at about this time, and their opinions as to the nature of the sore were the same.

About the middle of November, Prof. Donald MacLean of the University of Michigan, removed the growth before his class in surgery. The size of the ulcer at this time was about that of a silver twenty-five cent piece. The sides of the wound, which was about two inches long by one and a half wide, were drawn together and it readily healed.

In the spring of 1877 the epithelioma again made its appearance in the same place. A number of mild caustics and palliative remedies were used until the middle of November following. At this time the cancer was making a rapid progress. The ulcer was an inch in diameter. The infiltrated surface was some three or four inches square, extending from the ear forward to and including a portion of the conjunctiva and sclerotic. Mastication was interfered with, and he suffered greatly from the characteristic pains.

He now began the use of hot water four or five times daily, bathing the affected surface with it, and holding the side of his face in it, using the water as hot as he could bear it. Within a week the "darting burning pains" ceased and the face assumed a more natural appearance. He continued this treatment until the following May, when a cure had been effected. It is now three years since he ceased all treatment and there has at no time been any signs of a recurrence.

There seems to be no room for doubt as to the diagnosis given. The manner of the appearance of the growth, the character of the ulcer and its recurrence after removal, make sure of its malignant nature. As regards the use of the hot water, two theories of its action occur to me.

It has been determined that malignant growths depend for their existence upon the formation of certain cells. It is not unreasonable to suppose that a temperature of 120° to 130° F. would destroy the active life of the cells. It has been shown* that at a temperature of 104° F. the activity of the leucocytes ceases and their substance hardens.

One of the results of the application of hot water is a stimulation of the vaso-motor system, thus aiding nature in removing morbid products and in arresting morbid changes. The value of the use of hot water in surgery has been demonstrated.† I need not enlarge upon this theory of the manner in which the life of the growth might have been destroyed.

A. H. PHINNEY.

HOWELL, MICH.

## CAN A MAN GRADUATE WITHOUT HAVING SEEN A CASE?

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—Apropos of the question, "Can a man graduate without having seen a case?" in your journal of April 2d, it occurred to me that a *résumé* of the German Staats-Examen for Doctors might not be uninteresting to many of your readers, who may not be familiar with its details.

The conditions of admission to the examination are, that the candidate, as he is called, shall furnish evidence, 1, of having taken the prescribed courses in the gymnasium and at some university; 2, of having passed the examination in the natural sciences; 3, of having spent at least two semesters at a surgical and at a medical clinic, and of having taken charge personally of at least four labor cases at an obstetrical clinic.

This done, the candidate is examined in the following subjects, in their order:

1, Anatomy, physiology, and pathology; 2, surgery and ophthalmology; 3, medicine (theory and practice); 4, obstetrics and gynæcology.

Then follows a final oral examination, in which the candidate is expected to give public proof of his "general medical culture" in "such general and special matters of pathology, therapy, surgery, obstetrics, pharmacy, and *state medicine or hygiene*, as a doctor ordinarily meets in practice."

The examination falls into two parts, the theoretical and the practical. The theoretical consists of a quiz, lasting from ten to thirty minutes, on each of the topics, and these are conducted as with us.

The practical is very practical. In anatomy, the candidate must demonstrate preparations handed to him, and must himself dissect and demonstrate some nerve. He is given several days in which to make the dissection.

In physiology, besides having physiological exercises, he must make preparations for the microscope, demonstrate them, and "show his readiness in the use of this instrument."

The "marks" which the examiners use are "excellent," "very good," "good," "middling," "bad." Having received "good" in these subjects, the candidate may pass on, otherwise he must wait a while and begin again.

In surgery and ophthalmology, the candidate visits the hospital or university clinic with the examiner, and is assigned a case, of which he must give a diagnosis, prognosis, and plan of treatment. He is now left in a room alone with pen and paper, and given till late in the evening to write up the case. For the next seven days he must visit the case twice a day, and keep a journal of it. During this time he is examined on other cases which there may be in the ward, and required to show his readiness in minor surgery and in the use of the ophthalmoscope. He is also required to perform operations on the cadaver; give their value and indications; put up fractures; reduce luxations; and put on bandages.

In medicine, the same plan is pursued. The candidate is also required to write from ten to twenty recipes for pills, mixtures, etc., and to point out from fifteen to twenty medicines, and give the maximal and minimal doses of the same.

In obstetrics, the candidate is given a labor case to attend, and by the next morning after the birth he must return a written account of the same. He must visit the case and keep a journal of it for seven days, during which time he is examined on any other obstetrical and gynæcological material in the wards. He must prove his manual skill in turning, application of the forceps, etc., on the phantom.

All this requires about three months. Having passed through it successfully, the candidate is made a "Practicirender Arzt."

The degree of Doctor of Medicine is more an honorary title, to be obtained afterward by writing and defending a thesis.

The difference between this sort of examination and our five-minute quizzes, is too manifest to need pointing out. It seems to me that our medical journals could do no better service to medical progress in America, than to publish occasionally an "educational number," containing a *résumé* of facilities for medical studies, requirements for doctors, degrees, etc., in the different civilized countries, after the manner of the *London Record* and *Le Progrès Médical*. If American physicians, and medical students especially, were thoroughly acquainted with the standards in foreign countries, they would not long remain contented with the inferiority of our own.

Yours respectfully, CHARLES H. HUNTER.

STRASBOURG, May 13, 1881.

## NOTES ON THE ACTION OF CURARE ON THE MOTOR-NERVE ENDINGS.

### A REPLY TO DR. POOLE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In a recent article in the RECORD (May 27th) by Dr. Poole, the action of curare on the motor-nerve endings, as interpreted by the leading physiologists of the day and accepted by the scientific world, is discussed at length, and an endeavor made to prove that because certain possible fallacies attended the performance of the experiments, that it was the "duty of medical science to decline to accept the presumption that the ordinary effect of curare is to paralyze the motor-nerve endings and terminal filaments until other and reliable proof is offered in its behalf." But we cannot agree with the conclusions of this writer, which for obvious reasons are unjustifiable, and entirely unsupported by adequate proof—in fact, no proof at

* Williams: Pulmonary Consumption, p. 54

† Dr. Frank H. Hamilton in MEDICAL RECORD of May 15, 1874.

all save those of imagination, as we will learn from a discussion of his article.

From the results of the experiments made by Dr. Foster with curare on the frog, and which are quoted in Dr. Poole's paper, we learn:

*First*, That curare produces paralysis of voluntary motion and respiration, and sometimes causes mydriasis, strabismus, and convulsions.

These effects he (Dr. Poole) concludes point to an action on the *motor centres*.

*Second*, That electrical stimulus applied to the exposed sciatic nerve of a poisoned frog is unable to cause contraction in the muscle.

This he attributes as being due to a paralysis in the *motor trunk*.

*Third*, That if the muscle is now exposed, and an electrical current is applied directly to it, a contraction will result.

This he concludes *is because the terminal branches of the nerve are still irritable, and consequently are in a condition to be acted on by electricity in the usual manner*.

*Fourth*, That after tying the blood-vessels supplying the posterior extremities, by placing "a thread very tightly round the abdomen of a frog so as to check entirely the flow of blood to the lower limbs," and in such a manner that the functions of the sciatic nerves are not interfered with by compression of the ligature, that movements take place when stimulus is applied to a sensory surface in the posterior extremities in which the nerves are unpoisoned, but not in the anterior extremities.

"These nerves," he says, "being thus entirely free from compression and in full continuity with the spinal cord, are just as favorably situated for receiving a *paralyzing impulse from the cord*,* as are the motor nerves connected with the cord higher up. Why should they not be equally paralyzed as the nerves leading to the anterior extremities, for example, seeing both are equally susceptible to receive impressions from the cord?"

*Fifth*, That after ligating the blood-vessels of the right leg of a frog and thus preventing the access of poison below the ligature, and then poisoning the frog with curare, movements may be produced in the right lower leg, but in no other part of the body; and that if the nerve be exposed in both legs, the left (poisoned nerve) does not reply to stimulation, but the right (unpoisoned) does.

*Sixth*, That if a muscle be insulated from the rest of the body, except the motor nerve, and the frog poisoned, it is found that stimulation of the motor nerve will cause a contraction of the muscle when all the other motor nerves of the body seem to have lost their irritability; and that if only a small portion of the nerve immediately next the muscle be protected from the poison, the muscle may be made to contract by stimulus applied to any portion of the nerve-trunk.

Dr. Poole states that the first experiment proves "as fully as any physiological fact can be proved, that the ordinary effect of curare (or urari) is to paralyze the motor-nerve trunks and to spare the terminal nerve-branches." But just what experiment he means by "the first" is rather incomprehensible, for it certainly cannot mean the first one given, as there is nothing whatever in the result which would justify such a conclusion; and moreover, he concludes that the result points to an action on the motor centres. Nor can there be found in a single experiment quoted, proof to warrant such an assertion. Again we come in conflict with the uncertain "first experiment" when he states that "the after experiments are tainted by too many sources of fallacy to prove anything definite; but even as they stand they admit of a rational explanation in full accord with the results of the former experiment;" but still, as it is evidently meant that the paralysis of the nerve-trunk is the fact with which the explanation will accord, we can pass any unnecessary discussion by. However, when we come to critically examine Dr. Poole's deductions and assertions, we find them, on the whole, extremely illogical, and more in accord with the physiology of a generation ago than of the present day. His first conclusion is admissible, for there is sufficient evidence in the results to indicate that the drug does act on the motor centres. His second deduction is certainly unwarrantable, and there is no proof to sustain it, for it is certain that in a muscle-nerve preparation (which essentially we have in this instance) there are three physiological factors to consider in an experiment of this nature: 1, the condition of irritability of the nerve-trunk; 2, the condition of irritability of the nerve peripheries; 3, the condition of irritability of the muscle. Now, it is undoubtedly clear that nothing is proven by the result of this experiment, except that one or more of these factors are wholly or partially destroyed, and therefore, to assume that the *trunk* of the nerve shares the paralysis, without first deciding that neither the nerve peripheries or muscle is affected, is to assert what is unsupported by adequate or justifiable proof.

How to decide which of these three factors was concerned in this paralysis, as implied by the non-appearance of contraction of the muscle when the motor nerve was stimulated, was the object in the succeeding experiments, the first of the series being to make a direct application of electricity to the exposed muscle, and which was with the result of having a marked contraction follow. Now what does this prove? Certainly that the muscle possesses irritability, and that the paralysis must either be due to a paresis of the motor trunks or peripheries. But with this conclusion the writer does not agree, for he asserts that the reason why the muscle contracts by a direct application of stimuli is because the terminal branches of the nerve are still irritable, and he considers this a "very natural and rational explanation;" but which, as we think, is the very opposite. Over a century ago Haller* taught us that nerves and muscles possessed independent irritability, speaking of the nerve as possessing *vis nervosa*, and of the muscle as possessing *vis insita*, the former signifying the irritability which excites contraction, and the latter as the independent contractibility or irritability of the muscle. Since his time we have added certain facts going to certify to the correctness of the existence of independent muscular irritability: 1, if the lower end of the sartorius of the frog, which is destitute of nerves, is stimulated, distinct contraction of its substance will ensue; 2, if a minute portion of a muscle deprived of all nervous structure be placed on the stage of the microscope, it can be made and seen to contract; 3, chemical substances are different which stimulate nerves and muscles; 4, contractility is one of the fundamental properties of protoplasm, and occurs in organisms in which no nervous system whatsoever can be detected; 5, that after a nerve has com-

* The italics are mine.

* De Part. Corp. Hum. sentientibus et irritabilibus, 1753.

pletely lost its irritability, the idio-muscular irritability of the muscle may be elicited.

Now, the great mistake which we believe Dr. Poole makes in criticizing the results of these experiments, is in considering that the muscle does not possess independent irritability, but depends upon the irritability of the terminal branches of the nerve alone for stimulus to cause its contraction, evidently viewing these nervous structures as being mediating centres as it were, which are alone capable of receiving and transmitting the impulses which elicit muscular contraction; and he appears to be led into this error by misunderstanding a remark of Dr. Foster's, stating that "a muscular contraction is a token of an impulse passing along the nerve" to the muscle; but Dr. Foster certainly could not and did not imply the meaning as construed by Dr. Poole, for it is well known, from what has already been stated, that the motor nerves are but a single channel for conveying impulses capable of inducing muscular contraction. Dr. Poole states that "the proof that the terminal nerves were not poisoned in the first experiment, is that the muscular fibre contracted by the direct application of electricity." But, that this is no proof at all, is apparent from what has already been said.

Considering the fourth proposition, it is certain that the poison was prevented from gaining access to the posterior extremities, and, therefore, in so far as this toxic agent was concerned, the structures below the ligature remained in a normal condition. It is now apparent that if stimulus is applied to any sentient surface, if the sensory nerves and peripheries are intact, the impulse will be conveyed to the centres, and, if these centres were intact, would be reflected out through the motor nerves to the muscles. These experiments certainly show that the sensory nerves and spinal centres must be intact in the poisoned animal, as they were in this case, or they certainly could not convey, receive, and transmit impressions to the unpoisoned nerves, and, through them, to the muscles of unpoisoned limbs. Now it is certainly very clear that if the impulses are reflected through the unpoisoned legs alone, that the seat of paralysis must be either in the motor trunks, peripheries, or muscles. As already stated, Dr. Poole believes that this is further evidence to prove that the motor trunks are paralyzed; but the fact of the matter is, that it is merely evidence that some *part* of the peripheral motor apparatus is paralyzed and does not in any way specially indicate the motor trunks any more than it does the terminal filaments or the muscle. Moreover, he attributes the depression of the motor nerves to a "paralyzing impulse from the cord." Just what the meaning of a "paralyzing impulse from the cord" is, I have no conception whatever. Who ever heard of paralyzing impulse from the cord destroying the electro-irritability of the motor nerves. Such phenomena as paralysis of the motor nerves from excessive use, such as probably occurs at times in strychnia poisoning, has been observed, yet this can scarcely be what is meant, for the actions of the two drugs physiologically are very dissimilar.

In considering the fifth of the series, we find it stated that "the fallacy here is the assumption that when the entire blood-vessels, lymphatics, and sensory nerves are compressed by a ligature, so as to arrest the circulation, the processes of absorption [etc.], go on above the ligature just as in the limb left to its normal conditions," for, as he thinks, the difference is very material, and that the right nerve has not been supplied as freely with the blood (consequently the poison) as the left. But this statement is vastly overdrawn, as will be apparent after an examination of experiments with drugs which directly depress the motor-nerve trunks, and is, consequently, worthless. Still, while it will be admitted that the ligature must more or less affect the circulation immediately above it, yet it certainly does not materially affect the circulation near the spinal cord, and although when stimulus is applied to the nerve-trunk at this position, the impulse is transmitted to the muscle.

In the latter part of the paragraph (8d line, 1st column, p. 598) appears a misquotation, in which it is stated "Dr. Foster concludes that the nerve-trunk of the left sciatic was *unpoisoned*," which should read *poisoned*. His argument immediately following this, and which is based upon it, is consequently worthless. In the succeeding paragraph he asserts that the fact of the muscle contracting shows that the terminal nerves were intact, and, further, that the contraction would not have followed in the muscle by stimulating a nerve-trunk if the terminal nerves were paralyzed. Certainly not; there is no other conclusion.

In the following paragraph he admits that there is good reason for believing that curare does paralyze the terminal nerve-fibres, because in rapid and fatal poisoning the muscles sometimes pass into tonic or clonic spasms, and in explanation of this phenomena, says that it is "to be presumed that the intra-muscular nerve-endings *are* paralyzed, and the muscle promptly set free," meaning by this that the "property of contractility of the muscle" is set free; and hence the occurrence of spasm. Of all "quasi-scientific" conclusions, this beats them all. Every physiologist knows that muscle does not possess the power of automatic action, and just why it is that a muscle on being "set free" by curare will enter into such a marvellous performance is certainly, in the light of physiological knowledge, inexplicable. Did the writer ever try the effect of curare when locally applied to the muscle? In the very many times we have used it, we cannot recall a single instance of spasm being produced by a local application to the excised muscle. To assume that the convulsions are due to this cause, is *reductio ad absurdum*. Now, he says, "in death, during the convulsions of curare-poisoning, could so profound a paralyzer, by any possibility, assume the *rôle* of a stimulant to a nerve-function? Surely not." Let us admit the answer, yet may we ask if the writer knows of such a thing as convulsions being due to *depression?* We believe that such is the case, as was pointed out in a previous paper.

Considering the last proposition, in which the experiments go to prove that the motor-nerve endings were alone paralyzed, exception is taken in the first place, because a current was not directly applied to the muscle to see if it would contract; and, in the second place, because mutilation of the muscle and shock, and the shortening of the muscle after separations from its bony attachments, would serve to invalidate the result. Regarding the first instance, we know that if a muscle is severed from all vascular connection, it will retain its power of contractility for a considerable length of time, and a muscle poisoned with curare will still reply to stimuli, so that it was in this case wholly unnecessary, and entirely uncalled for, to test the muscle, which undoubtedly retained its irritability. In the second instance, it seems obvious that the effects of mutilation, shock, etc., would impair the amount of response in the muscle, if anything, and furnish the

opposite result from what it did, and the very fact of the muscle responding so admirably under such circumstances is strong proof in Dr. Foster's favor. Dr. Poole's hypothesis, that the shock prevents the absorption of the poison, is overdrawn, and it is not taken into consideration that absorption goes on without the intervention of the nervous system.

Finally, he states that "wherever the nervous appendages and nerves are really found paralyzed, the contraction of the muscle will be found present as a contemporaneous fact," yet on the previous page he states that "proof that the terminal nerves were not poisoned . . . . is that the muscle contracted to the direct application of electricity." This is directly contradictory.

Considering all things, it is evident that the "quasi-scientific" conclusions rest with him, and not with Dr. Foster and his fellow-believers.

EDWARD T. REICHERT, M.D.

106 HALSEY STREET, NEWARK, N. J.

## ARMY NEWS.

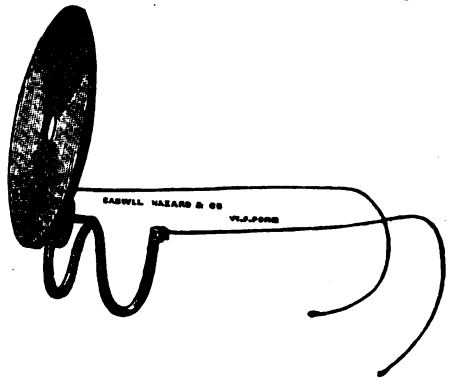
*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 26, 1881, to July 2, 1881.*

KOERPER, E. A., Capt. and Asst. Surgeon. Granted leave of absence for two months and fifteen days. S. O. 143, A. G. O., June 24, 1881.

## New Instruments.

### AN AURAL AND LARYNGEAL HEAD MIRROR.

THIS is a convenient and portable instrument that may be safely carried in the pocket in a case, or introduced into the aural and laryngeal pocket-case. The mirror is attached to a spectacle frame, which increases its weight but little, and when worn upon



the head it is certainly much cooler than any arrangement with an elastic band. It has another advantage, it does not disarrange the hair of the head. This device has been perfected by Mr. Ford, of Messrs. Caswell, Hazard & Co.

EXAMINATIONS IN SANITARY SCIENCE will be held by the Michigan Board of Health on July 12th. Certificates are given to those passing the examinations satisfactorily.

## Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending July 2, 1881.

INTERNATIONAL MEDICAL CONGRESS.—Delegates for the International Medical Congress are requested by the Hon. Secretary General, Dr. MacCormac, 13 Harley street, W., London, Eng., to inform him of the fact without delay, in order that suitable provisions may be made for hotel and lodging accommodations. Addresses of delegates may also be sent to Dr. Bulkley, 1 East 33d street, New York.

IODOFORM IN UTERINE AND CATARRHAL DISEASES.—Dr. Fowler, of Youngstown, O., makes a pliable mass for iodoform by mixing it with isinglass and glycerine. The isinglass is reduced to a jelly by steam, and enough glycerine is added to give it consistency and pliability. The proportions are as follows: Iodoform, ʒ j.; isinglass, ʒ viij.; glycerine, ʒ iv.

CONCERNING STRONG INJECTIONS IN GONORRHŒA.—Dr. John Ashhurst, of Philadelphia, in referring to some typographical errors in a recent report of his clinical lecture, writes: "I wish to protest that I do *not* use, in gonorrhœa, injections of SIX OUNCES of acetate of lead to TWO OUNCES of water, nor do I attempt to cure CHANCRE with camphor and opium suppositories; I think *two scruples* to *six fluid-ounces* quite strong enough for the injection, and it is *chordee*, not chancre, the pains of which I attempt to relieve by the rectal administration of anodynes."

INDIANA STATE MEDICAL SOCIETY.—Dr. William Commons, of Union City, Ind., writes: "In noticing the late meeting of Indiana State Medical Society, in RECORD of June 25th, you say, 'Resolutions were adopted to the effect that it is not the sense of this society that we have observed deleterious effects to the public health from the use of cooked pork; the disease called hog-cholera, and the disease called trichinæ is seldom met with in this country.'

"The statement is an error, which please allow me to correct. Such a resolution was introduced, but its declaration and import were so in opposition to observed facts, and so inimical to public health, that the society did not even give it the recognition of a vote, much less adopt it. The question of relation between hog-cholera and trichinosis was referred to a committee of five, who are to make observations and report next year."

THE ADIRONDACKS AS A HEALTH RESORT FOR CONSUMPTIVES.—As we predicted, the somewhat highly-colored article on the Adirondacks as a health resort, published in *Harper's Monthly* some months ago, has sent a crowd of consumptives to the St. Regis region.

It is said that already fourteen persons have died in the mountains, or on their way there, in the month of June.

So far as we can learn, the accommodations and food to be found ordinarily, are not very good.

At any rate, it behoves the profession to be very careful in recommending the resort.

THE UNIVERSITY OF VERMONT conferred, on the 29th of June, the degree of LL.D. on Dr. D. B. St. John Roosa, of this city. A well deserved honor.

CANADA.—The Ontario Medical Association held its annual meeting at Toronto, June 1st and 2d. Quite a large number of papers were read, and the meeting was considered a successful one.

The Canada Medical Association will meet at Halifax, N. S., on August 3d.

Dr. J. Fulton, the accomplished editor of the *Canada Lancet*, has been appointed Professor of Surgery in the Trinity Medical College, at Toronto.

THE ORDER OF THE KNIGHTS OF THE GOITRE are principally found in Switzerland. Its members are all swells.—*Puck.*

THE STATE BOARD OF HEALTH OF WEST VIRGINIA has been organized, with the appointment of Dr. J. E. Reeves as president.

THE ANNUAL MEETING OF THE ASSOCIATION OF MEDICAL SUPERINTENDENTS OF ASYLUMS in United States and Canada, was held at Toronto, June 14th.

JEFFERSON MEDICAL COLLEGE has lengthened its term one month. The term will hereafter begin the first week in September and end the last week in March. So says the college organ. According to the annual announcement, however, the term begins October 3d, it being preceded by a preliminary term of three weeks, as is usual in many colleges, and the lectures cease in the third week of March.

ASSISTANT SANITARY INSPECTORS.—The regular corps of fifty assistant sanitary inspectors for the summer, has been appointed by the City Board of Health. They will begin work some time in this month.

DR. KIDD AND THE LATE LORD BEACONSFIELD.—Dr. Kidd, who has been very unjustly sneered at by the *Lancet* and a few other patriarchal journals, writes a second letter in defence of himself. Much comment was made upon Dr. Kidd's having "one set of convictions" while Sir William Jenner and Gull had another. Dr. Kidd states that for several months before he was first called in to attend on Lord Beaconsfield, Jenner and Gull had been in attendance. They failed to secure any relief for the patient. Dr. Kidd was then called in. By the application of his "set of convictions," which he distinctly states are not homœopathic, he gave relief to his patient, and was retained as his medical adviser for the subsequent three and a half years of his patient's life. In this case the "one set of convictions" appeared to be simply a wider experience or better knowledge of the trouble from which his lordship suffered.

With reference to the assertion of the *Lancet* that Dr. Kidd's name was still in the homœopathic directories, he states that before the *Lancet's* article appeared he had written asking his name to be withdrawn.

We are not specially desirous of championing Dr. Kidd, but there has been a display of stupid conservatism and injustice toward him in some quarters which we are sure does not at all represent the feeling of the medical profession in general. Dr. Kidd, in profession and practice, stands now, so far as we can learn, on the same plane with other reputable practitioners. The zeal and self-denial of Sir William Jenner for the honor of the profession were well-intended, but utterly mistaken. His action and the controversy it aroused have tended to belittle the profession in the estimation of many.

WHAT VACCINE VIRUS ARE WE USING NOW?—The fact that small-pox is still as prevalent as ever in this city makes the above inquiry a very pertinent one. In a discussion on the subject of vaccination before the Medical Society of Kings County, Dr. J. H. H. Burge asserted that there are now in use six or seven kinds of vaccine virus. These he enumerates as follows: 1, we have, perhaps, virus direct from the natural vaccinia; 2, we have humanized virus, originally from the natural bovine vesicle; 3, a virus resulting from humanized virus introduced again to the system of the cow and brought back to man; 4, probably a virus resulting from inoculation of the cow with small-pox matter; 5, it is not impossible that we have a virus from other vesicular diseases in the cow resembling vaccinia; 6, we have the calf-to-calf virus, originally from the true natural kine-pox, and descending through a long line of induced cases of vaccinia.

Dr. Oscar C. De Wolf, Chicago Health Commissioner, replies to this in a paper read before the Chicago Medical Society (*Chicago Medical Review*). He says that Dr. Burge's statement, if true, is a grave impeachment of vaccine cultivators in this country. Dr. De Wolf then reviews the evidence upon the subject, and concludes that the virus now in use is really from the following four sources: 1, the Beaugency stock, introduced by Dr. Martin; 2, the Belgian stock, also introduced by Dr. Martin and by Dr. Griffin; 3, the culture of Dr. Griffiths, of Brooklyn, from a case of spontaneously appearing disease observed by him in the State of New York; 4, humanized virus from all the above stocks.

THE INTRAVENOUS INJECTION OF AMMONIA, in surgical collapse, has recently been tried by Mr. Thomas E. Clark, of Bristol, England, and with gratifying results. He urges a more extended use of the method in conditions of collapse.

MASSACHUSETTS COLOR-BLIND LAW.—Through the energetic efforts of Dr. B. Joy Jeffries, of Boston, and a few others, the Legislature of Massachusetts has been persuaded to pass an "Act Relative to the Employment by Railroad Companies of Persons Affected with Defective Sight or Color-Blindness." The first part reads as follows:

"SEC. 1. No railroad company shall employ or keep in its employment any person in a position which requires him to distinguish form or color signals, unless such person within two years next preceding has been examined for color-blindness or other defective sight, by some competent person employed and paid by the railroad company, and has received a certificate that he is not disqualified for such position by color-blindness or other defective sight."

The law is an excellent one, in that it calls for an examination for color-blindness. There is an unnecessary stringency, however, in its requiring a new examination every two years, and this may defeat its object. Furthermore, there is often an absurdity in passing men as having good vision because they are not color-blind. It certainly seems as

though the existence or non-existence of normal visual acuity ought also to be recognized. Under the above color-blind law, a myope or half-blind person could act, while a man with perfect vision, except for a little achromatopsia, would be rejected.

COMPULSORY CLINICAL ATTENDANCE.—In reference to the above subject, which is now being agitated, we are informed by Dr. M. W. Baker, Dean of the Woman's Medical College, that compulsory medical attendance has existed in that institution for many years. It is one of the few colleges in this country where a person "cannot graduate without seeing a case."

FIRST BIENNIAL REPORT OF THE NORTH CAROLINA BOARD OF HEALTH, 1879–80.—The first report of the North Carolina Health Board is most creditable to the energy and intelligence of its officers. The difficulties in the way of making the board a useful organization have been great. But little money was given it, and its efforts to collect vital statistics were met with great indifference by local authorities and medical men. Still much has been accomplished, especially in the way of supplying the people with sanitary knowledge by means of circulars, etc.

The present volume contains some articles of more than usual value. Among these are "Reports on Drinking-Water;" "Methods for Performing Post-mortem Examinations," adapted from the German regulations by the secretary, Dr. Wood; a circular on "Ventilation, Drainage, Drinking-Water, and Disinfectants," and an article on "Sanitary Engineering," by William Cain, C. E.

THE TENTH ANNUAL MEETING OF THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE was held on April 14th, at Algiers. M. Rochard presided over the section of medical sciences. There seems to have been very little of interest done. M. Verneuil made a communication on "The Relations of Malarial Poisoning to Surgery." The subjects of "The Treatment of Hæmorrhoids by Cold Water," of "Goitre," and "Vesico-vaginal Fistula," occupied the first day. The association was opened with a long discourse by Chaveau on "Ferments and Virus;" "Physiological Researches on the Action of Hellebore," "Treatment of Goitre by Capillary Electrolysis," "Amputation of the Cervix Uteri," "Pulsating Tumors of the Orbit," "Local Treatment of Diphtheria by Constant Application of Papaïne," "Physical Education of Infants," were among the subjects discussed on the second and third days.

M. Herard made a communication, in which he showed that hydropneumothorax sometimes had a favorable influence on the progress of phthisis. M. Caussidon advocated the treatment of typhoid fever with salicylate of soda. M. J. Boeckel related two cases of intestinal occlusion saved by laparotomy. M. Poncet made a communication on the subject of intraperitoneal cancers. Dr. Berthirand read a paper on "Sea Baths in the Treatment of Eye Troubles." M. Cornil described micrococci and bacilli found in diphtheria. M. Gillet de Grandmont showed some instruments for measuring the acuity of color-vision in the central and periphirec fields.

The meeting lasted four days. A good many physicians from France attended, but not enough to make the medical section amount to much.

LEPROSY IN LOUISIANA.—In connection with the effort initiated by the New York Academy of Medicine, to investigate the subject of leprosy in the United States, the report of the Louisiana Board of Health for 1880 contains some interesting statements. It gives a history of the progress of leprosy in that State during the last and present centuries. The disease was brought in 1680 to the West Indies by the negro slaves, and thence to Louisiana. In 1778 this disease was so prevalent among the blacks, together with the African elephantiasis, and another equally horrible, named yaws, peculiar to Guinea negroes, that a hospital for lepers was established in New Orleans. At the present time the majority of lepers in that city are found to be whites, of French, German, and Russian extraction. It has shown itself to be hereditary, and probably contagious.

An Italian Catholic priest, who attended cases of leprosy in the Charity Hospital, is now dying of it in the same house. Yet New Orleans, it appears, has no separate asylum for these incurable patients, and they are received into the Charity Hospital and placed in the crowded wards to scatter death.

The president of the Board of Health has made a personal investigation into the extent of this disease, even venturing into the swamps of the lower Bayou Lafourche. This whole district, he states, is several feet lower than the turbid bayou, sloping back into cypress swamps liable to constant overflow from crevasses. The poor Creole inhabitants live in low huts surrounded by wet rice-fields, living upon fish and fish-eating birds. They are separated from the rest of the world and have intermarried for generations. So impregnated with disease is this remote region that some of the exploring party were struck down on reaching it with violent hemorrhages and fever. Of all foul corners of the world it is the fittest for the disease most dreaded by man since the beginning of the world to hide with its prey. Below Harang's Canal, President Jones found Asiatic leprosy existing in different generations of six families. Some of these wretched creatures have been driven out from human habitation, and are living apart in the swamps, dying of decay. It was impossible to make a correct estimate of the cases, as a rumor spread among them that the searching party had come to carry them off to an uninhabited island of the sea, and they hid themselves, their friends, too, refusing to tell their names or number.

ALLOCHEIRA is the name applied by Professor Obermeister for the subjective error of locating an impression on the opposite side of the body to that where it is applied. Several cases are related of this curious affection. In one the man had syphilis, in another he had received an injury of the spine. In all cases the sensibility, as tested by the æsthesiometer, was normal.

PECULIARITIES OF TYPHOID FEVER AS IT OCCURS IN CHILDREN.—Dr. Henry Ashby, in *The Practitioner*, makes some notes upon typhoid in children. These may be summed up as follows:

*First.*—The disease is milder in children than in adults. The per cent. of mortality averaged, in two hundred and sixty-five cases, eight.

*Second.*—The susceptibility to the disease is greater in children.

*Third.*—The typhoid of children more often aborts—*i. e.*, runs a course of two weeks, instead of three or four—than the typhoid of adults. As a rule, such cases are not accompanied by much diarrhœa, and do not relapse.

*Fourth.*—The onset, in the majority of fifty cases analyzed, was gradual. In the minority of cases there was a slight shivering.

*Fifth.*—The morning remissions of fever are

greater than in adults. The highest temperature is reached between four and eight P.M.

*Sixth.*—Rose-spots appeared in seventy-eight per cent. of the cases, which is smaller than the per cent. usually given for adults.

*Seventh.*—Hemorrhage from the bowels and perforation are rare.

*Eighth.*—Relapses are not uncommon.

*Treatment.*—Not much medicine is advised. The pyrexia being combated chiefly by cool sponging and baths, or, occasionally, by quinine. As regards diet, the invariable rule has been to give milk only. The mixing raw egg with it is not believed to be an improvement. The peptonized milk, or milk gruel, as recommended by Dr. Roberts, was found very valuable.

For Orthopnœa, due to defective heart action, free purgation, with the hourly administration of digitalis and nux vomica, are recommended by Dr. H. Cook.—*Practitioner.*

An Interesting Illustration of the valuelessness of some of the conclusions of foreign experimentalists is shown in a recent elaborate paper by Afanasieff. He treated *seven* cases of typhoid fever with the lukewarm bath, according to a new method, and deduced three conclusions therefrom. The baths were a modified form of the Riess method. The patients were kept in water at a temperature of 88° F. for three hours at a time. We are confronted with the surprising deduction that such baths reduce the temperature. The per cent. of mortality is not given.

Cupric Test Pellets.—Dr. H. G. Piffard writes to the *Medical and Surgical Reporter*, asserting his claim to the invention of cupric test pellets, which honor some are disposed to confer on Dr. Pavy, of London. Dr. Piffard's formula is as follows:

| | | |
|---|---|---|
| ℞. | Cupri sulph. (pure)..... | 1 part. |
| | Sodæ et potas. tart. (cryst.).. | 5 parts. |
| | Sodic hydrate (pure)..... | 2 parts. |

Mix thoroughly in a mortar; the more labor spent in this the better the product. Put a piece of the pasty mass thus made, about the size of a C. C. pill, into a test-tube. Add two drachms of water, and boil till the mass is dissolved. The solution has a uniform pale and rather dirty blue color. Add two or three drops of the suspected urine and boil again for a moment. If sugar be present the usual reaction will be manifest.

Periods of Incubation of the Communicable Diseases.—Dr. B. W. Richardson gives a list of twenty-five communicable diseases which have a period of incubation. He adds a list of eleven diseases concerning which it cannot be said certainly that they have a period of incubation. These latter are; Catarrh, puerperal fever, pyæmia, hospital gangrene, sloughing phagedæna, phagedæna, remittent fever, intermittent fever, choleraic diarrhœa, cerebro-spinal fever, carbuncle.

The diseases attended with stages of incubation are conveniently divided into five groups:

*Shortest*—Incubation one to four days: Malignant cholera, malignant pustule, plague, catarrh, dissection wound diseases.

*Short*—Incubation two to six days: Scarlet fever, rosalia idiopathica, diphtheria, dengue, erysipelas, yellow fever, pyæmia, influenza, pertussis, glanders, farcy, grease, croup, puerperal fever.

*Medium*—Incubation five to eight days: Relapsing fever, gonorrhœa, vaccinia, inoculated variola.

*Long*—Incubation ten to fifteen days: Small-pox, varicella, measles, rötheln, typhus, typhoid, mumps, malarial fever.

*Longest*—Incubation forty days or more: Syphilis, hydrophobia.

Phthisis without Cough.—In a recent clinical lecture (*Maryland Medical Journal*) Dr. William H. Thomson called attention to certain cases in which the cough of phthisis is entirely suspended. Such an event may occur when there is a drain upon the system in some other direction, as when diarrhœa, or chronic suppuration, or large excretion of urine sets in. One patient, whose history was given, had a phthisical cough and a very large cavity in the right lung. A psoas abscess appeared and the cough stopped entirely during the two years in which the suppuration continued, but it began again when the abscess healed up, and the patient soon after died. In another case, a woman was being treated for abscess about the ileo-cæcal valve, from which pus was constantly discharging, sometimes externally, sometimes internally. The patient had no cough, and no phthisis was suspected; but one day the lungs were examined and a large cavity found.

Another case of similar character was that of a patient in Roosevelt Hospital, who was being treated for diabetes insipidus. He was passing from seventy-seven to one hundred ounces of water daily. He had no cough. He was finally put upon opium and valerian. His urine lessened in quantity, even to forty-seven ounces a day. But a cough set in; his lungs were discovered to have a large cavity. The former treatment was stopped, but the cough continued, and the patient died of phthisis in a few weeks.

Religion as a Therapeutic Help.—It is not often that scientific men enroll religion among therapeutic agencies. Dr. Stephen S. Alford, however, in an article on the "Practical Treatment of Dipsomania," does this. After recommending total removal, of alcohol from the patient in acute attacks, with substitution of bromides, capsicum, Russian baths, acidulated drinks, diluent foods, etc., he advises tonics and a gradual education of the moral strength. He says: "Religious influence is important in the second and subsequent stages of treatment, and to sustain the abstinence that must be religiously observed under all circumstances throughout life. This conquest of self, and keeping the morbid craving in subjection, few men can accomplish. At times, even after years of abstinence, the desire will be most distressing and overpowering. It is refreshing, under such circumstances, to recognize and experience the existence of a higher power, who will give the necessary help to all who really believe and ask for it."

The author thinks that the percentages of recoveries from inebriety in England is about what it is estimated to be in America, *i.e.*, about one third recover, one-third improve and relapse, one third are not benefited.

Oliver Wendell Holmes on Pathological Anatomy.—At the recent presentation of a portrait of Dr. J. B. S. Jackson to the Boston Medical Library Association, Dr. Holmes made some very happy remarks regarding Dr. Jackson and his favorite study, pathological anatomy. Referring to Dr. Jackson's

activity as a member of the Boston Society for Medical Improvement, he said, "I recollect the days in which, with at least as much truth as there was in Louis XIVth's saying he was the throne, it might have been said that Dr. Jackson was the society. He was its support, its main pillar, untiring and untirable as a marble caryatid—say, rather its vertebral centre, around which all its limbs and organs were disposed. Did others fail to appear, he was always present; were others silent from lack of material for discourse, he was always ready with the story of some new and interesting case; had others brought no specimen, he was always sure to unwrap some embryonic *jeu d'esprit* of nature, or some fragment of unenviable personal property not mentioned in the late owner's will or codicil. He has left the memory of all this in the two imperishable fluids—ink and alcohol; in his minute and trustworthy records, and in the jars where the liquid that destroys the organs of the living, confers a kind of immortality upon the viscera of the dead. . . Dr. Jackson would never meddle with the microscope; he was always contented with his natural lenses of ten inches of focal distance. And thus, whatever he lost, he escaped one of the not infrequent effects of over-reliance upon the instrument to which we are under infinite obligations, but which is breeding a generation of intellectual myopes as one of its results."

Cremation in Denmark.—A new impulse to cremation has recently been given by the organization and work of the society in Denmark. At a meeting held in Copenhagen, May 31, it was shown that the society counted fourteen hundred and nine members, among whom were eighty-three physicians and some prominent clergymen. Opposition and prejudice have to a large extent died away, even among clergymen.

In the furnace projected by the Danish society corpses are to be reduced to ashes in a little over one hour, and it is calculated that the cost of incineration will be reduced to the insignificant sum of from three to five crowns—between one and two dollars. This economical feature of the project has met with great favor among the poorer classes, who complain that it is expensive to live, but much more expensive to die in the Danish capital.

Leprosy in Key West, Fla.—A correspondent of the *Tribune* recently sent what appears to be a somewhat sensational account of leprosy at Key West, Fla. He says: Some three years ago, while on the island of Key West, Fla., I was surprised to find leprosy there in all its horror, and making bold to speak of the matter, I was immediately condemned for attempting to injure the commercial prosperity of the place, and particularly in destroying its reputation as a resort of Northern invalids. The reputation seemed to dwell only in the minds of the sanguine, for but few invalids would risk their lives in a place like Key West, notorious for its yellow fever. However, I was stationed at Key West for six or seven years, and can confidently state that there are many cases of leprosy on that island, whole families being afflicted with it, and in several instances it was found in its worst form. No provision is made for the unfortunates; they dwell surrounded by the masses, intermarrying, and die. To strangers who happen to discover the truth, it is a source of continual anxiety, for one does not know when wash-clothes may be returned impregnated with the poison. This disease has been thoroughly and undeniably traced to the English possessions in the adjacent islands. I can assure you if a cautious and honest investigation is made in that locality the result would astonish the people of this country. A selfish spirit prompts the leading people of that beautiful but poisonous island to disguise the real state of affairs existing there, and I would take but little comfort in smoking a genuine Key West cigar, knowing of the existence of these horrible facts. The summer of 1880 in this island is locally notorious for its yellow fever horrors: still the press of the country would lead one to suppose there existed there but a few passing cases. Only Government officials, like myself, know of these horrors, and strangers have been repeatedly lured there only to find a grave. I have no personal interest in condemning Key West, but am only possessed of a desire to warn the ignorant and confiding, and condemn the wicked and selfish, who, being saturated with the poison themselves, are reckless for gain and indifferent of results.

The British Encyclopædia and Homœopathy.—The homœopaths have long been unsatisfied with the tone of the article on "Homœopathy" in the "Encyclopædia Britannica." This same protest was made many years ago when the first editions came out, and some promises of change were made by the American publishers. Nothing was done, however, and in the present edition the article is as offensive as ever. It is now said that a Dr. Cooper is to be sent over to London this summer by the homœopaths to protest officially against the article and insist upon its change.

The Sleeping Hungarian, whose case was reported in the Record as one of trance-coma, has begun to show some signs of returning consciousness. He has spoken several times. He said he belonged to the Slavonic race and could speak Hungarian. His mind wanders a little, but his condition improves. He had been asleep for one hundred and thirty-five days.

Artificial Impregnation.—In a recent communication to the Société de Biologie, Dr. De Sinéty discussed the subject of sterility in the male. He was inclined to think that in families without children the cause was oftener in the male than had generally been supposed. The usual test of procreative power on the part of the male is an examination of the spermatic fluid. If spermatozoa are found, it is considered evidence that the man is potent. In three instances described by Dr. Sinéty, however, this conclusion seems to be made doubtful. In these cases there seemed to be nothing in the condition of the wives to explain their sterility. Spermatozoa were found in the spermatic fluid of the husbands. In order to be sure that the spermatic fluid reached the interior of the uterus, artificial impregnation was resorted to. Shortly after the menstrual flow this was repeated, at intervals, six times, but without avail. The fresh spermatic fluid had been examined and found to contain many spermatozoa. But it was at last noticed that these spermatozoa, though very numerous, were for the most part immobile, and that movements soon ceased even in the few where they were first noticed. The observer's attention was awakened by this, and he examined the fluid in the two other cases with the result of finding the same condition. Two of the patients had tuberculosis, and the third was much debilitated.

## NOTES ON THE USE OF PEPSINE IN MEDICINE,

### WITH RECOMMENDATIONS REGARDING SACCHARATED AND PURE PEPSINE.

That many of the diseases from which mankind suffer during infant and adult life are caused by malnutrition, there can be no doubt; and the extent to which non-assimilation of the life-giving properties of food interferes with recovery from severe illness, baffling the best-directed efforts of the physician, points the necessity for an agent sufficiently potent to replace the deficient principle and aid nature in renewing the degenerated tissues.

Realizing this need, the science of chemistry produced pepsine; and even if medical literature were silent as to testimony of the results obtained, the large amount manufactured and consumed would amply attest its usefulness. But such is not the case, for, after long and careful investigation on the part of practical therapeutists, it is accepted as the remedy *par excellence* in all cases where the gastric juice fails to afford a sufficient amount of ferment for the reduction of aliment to a condition suitable for healthy assimilation.

As the undoubted value of pepsine as a remedial agent became evident, competition in its manufacture was stimulated; and as a natural result, the supply was varied both in purity and strength, and the medical profession, while anxious to avail themselves of its usefulness, were nearly as often misled into erroneous conclusions regarding its efficacy, as satisfied with its results—solely in consequence of their misfortune in not using such qualities as were likely to produce the much-lauded effects. Under these circumstances, a definite understanding regarding reliable preparations is desirable and of great importance. Pure pepsine, without acid, thoroughly triturated with finely powdered sugar of milk (saccharated pepsine*), will, without doubt, produce the perfect results in all cases where the remedy is exhibited.

Routh, in his "Infant Feeding," gives an account of a result obtained in the case of an infant. "Small, wrinkled, emaciated, four days old, yet presenting almost the appearance of decrepitude. The voice was weak, but distinct, and respiration not obstructed. The mother was an excellent nurse, but, although the infant took the breast readily, it constantly threw up every meal. What passed through the bowels was unchanged, although slightly tinged with bile. Diarrhœa was also present." The usual external remedies were applied, but without avail. "Emaciation was on the increase; the child was, in fact, dying." At this stage saccharated pepsine was administered, fifteen grains divided into ten powders, mixed with a little of the mother's milk, and after the second day the diarrhœa ceased and the child appeared much stronger. Twenty days of this treatment and the child was quite well. The eminent author adds: "This is a case which speaks strongly to the convictions. If, at so early a period of life, when vitality and digestion were so weak, the artificial pepsine effected a cure, *a fortiori* will it be likely to do so in the case of older children; and so I have found it in practice. The digestive powers are thus assisted, and the food, which before was useless, because undigested, readily becomes assimilated."

When administering pepsine, the slight acidity of the natural fluid should be produced as nearly as possible; and as the necessities differ with the circumstances, it is desirable that the preparation be quite free from acidulation, and the proper dose be given in combination with the requisite amount of dilute acid. Of Kidder & Laird's pure pepsine, five to ten grains, for an adult, can, if necessary, be taken in an ounce of water with five drops of muriatic acid.

For infants, however, the saccharated pepsine will be found to yield the most satisfactory results, and the acid should be dispensed with. Quantitively it represents one-tenth of the strength of pure pepsine; but it has been found to be but about one-fourth less in efficacy. The absence of acid, which would otherwise tend to produce harmful results, will be recognized when it is considered that even the slight acidity of most cow's milk, when used as food for infants, is sufficient to disagree with them.

With regard to the proper time for its administration, as before or after the taking of food, opinions vary, but reason would suggest that about half an hour before eating will afford the ferment a sufficient time to combine with the existing condition of the stomach, and produce the most natural effect upon the food when it has been acted upon by the salivary fluids in its passage to the stomach.

When once the formation of peptone has been established in the stomach, and as strength is acquired, the system will soon respond toward resuming the natural production of its normal fluids. Thus it is that many of the disorders of digestion which accompany severe attacks of fever, phthisis, etc., and also the exceedingly sensitive condition of the stomach, caused by vomiting in pregnancy and alcoholism, are controlled, and a natural condition resumed.

Having mentioned the necessity of great care in the selection of pepsine, with reference to its purity and strength, it is proper to say that, even with the superior article above recommended, negative results may be obtained, unless attention is given to the form of its administration. Combinations beyond those above mentioned are not advised, but rather discouraged, as many of the substances usually recommended as efficacious with it are incompatible and render the pepsine inert.

* Saccharated pepsine, free from acid, is prepared by Messrs. Kidder & Laird, No. 88 John street, New York, who generously furnish samples of both this and the pure pepsine, free of charge, upon application.

# For Consumption and Wasting Diseases.

# HYDROLEINE

*Has been proved of the highest value in CONSUMPTION and all WASTING DISEASES, invariably producing IMMEDIATE INCREASE in FLESH and WEIGHT.*

## FORMULA OF HYDROLEINE.

***Each dose of two teaspoonsful, equal to 120 drops, contains:***

| | | | |
|---|---|---|---|
| **Pure Oil** | **80 m. (drops.)** | **Soda** | **1-3 grains.** |
| **Distilled Water** | **35 "** | **Boric Acid** | **1-4 "** |
| **Soluble Pancreatin** | **5 grains.** | **Hyocholic Acid** | **1-20 "** |

**DOSE.—Two teaspoonsful alone, or mixed with twice the quantity of soft water, to be taken thrice daily with meals.**

*The principles upon which this discovery is based have been described in a Treatise on* "THE DIGESTION AND ASSIMILATION OF FATS IN THE HUMAN BODY," *by* H. C. BARTLETT, Ph.D., F.C.S., *and the experiments which were made, together with cases illustrating the effect of Hydrated Oil in practice, are concisely stated in a Treatise on* "CONSUMPTION AND WASTING DISEASES," *by* G. OVEREND DREWRY, M.D.

*In these Treatises the Chemistry and Physiology of the Digestion of the Fats and Oils is made clear, not only by the description of a large number of experiments scientifically conducted, but by cases in which the deductions are most fully borne out by the results.*

☞ ***Copies of these valuable works will be sent free on application to all who mention THE MEDICAL RECORD.***

## HYDRATED OIL

# HYDROLEINE

## WATER AND OIL.

*May be described as partially digested oil, which will nourish and produce increase in weight in those cases where oils or fats, not so treated, are difficult or impossible to digest. In* CONSUMPTION *and other* WASTING DISEASES, *the most prominent symptom is* EMACIATION, *of which the first is the starvation of the fatty tissues of the body, including the brain and nerves. This tendency to emaciation and loss of weight is arrested by the regular use of* HYDROLEINE, *which may be discontinued when the usual average weight has been permanentaly regained.*

*The ordinary so-called emulsions of Cod-Liver Oil and other fats,* WHETHER PANCREATIZED OR NOT, *merely remain in the form of a course mechanical mixture for a short time after agitation. The digestion of oil, having in no sense been artificially produced, still devolves upon those functional powers, the deficiency of which is the most prominent symptom in these cases.*

HYDROLEINE *is not a patent medicine or a secret preparation; the formula is on every bottle. Can be taken by the most delicate stomach; is immediately assimilated.*

*The permanence and perfection of the emulsion, and the extreme solubility of the* HYDRATED OIL, *solely prepared and sold by us under the name of* HYDROLEINE, *is shown by its retaining its cream-like condition as long as the purest Cod-Liver Oil will retain its sweetness. Unlike the preparations mentioned, or simple Cod-Liver Oil, it produces no unpleasant eructation or sense of nausea, and should be taken in such very much smaller doses, according to the directions, as will insure its complete assimilation; this, at the same time, renders its use economical in the highest degree.*

*To brain-workers of all classes, Hydrated Oil is invaluable, supplying as it does the true brain food.*

*Economical in use—certain in result. Tonic—Digestive and Highly Nutritive.*

## WILLIAM F. KIDDER, Agent for the United States,

**Depot, 83 John Street, - - NEW YORK**

# HYDROLEINE OR HYDRATED OIL AS A THERAPEUTIC AGENT IN WASTING DISEASES.

By W. H. BENTLEY, M.D., L.L.D.,
VALLEY OAK, KY.

In October, 1880, I read an advertisement of Hydroleine in some medical journal. The formula being given, I was somewhat favorably impressed, and requested the two pamphlets that the advertiser, Mr. William F. Kidder, of 83 John street, New York, proposed to send: One on "The Digestion and Assimilation of Fats in the Human Body," and the other on "The Effects of Hydrated Oils in Consumption and Wasting Diseases." In due time I received the pamphlets. They are ably written, and afford an interesting study. Their doctrines are so reasonable, that I got up faith enough to have my druggist to order a sufficient supply to thoroughly test the merits of the preparation.

I was ready to catch at anything to take the place of cod-liver oil. In my hands it has proved an utter and an abominable failure in ninety-five per cent. of all my cases in which I have prescribed it since I have been engaged in country practice, and it never benefited more than forty per cent. of my city patients.

The inland people, who seldom eat fish, can rarely digest cod-liver oil. Almost every week I am consulted by some victim of the *cod oil mania* who has swallowed the contents of from one to twenty-five bottles, and who has been growing leaner, paler, and weaker all the while, until from a state of only slight indisposition, these patients have become mere "living skeletons." Nearly all complain of rancid eructations, and an unbearable fishy taste in their mouths from one dose to another. They not only fail to digest the cod oil, but this failure overloads the digestive organs to such an extent that digestion and assimilation of all food becomes an impossibility, the patient languishes and pines, and finally dies of *literal starvation*. In the comparatively small number with whom I have found cod-liver oil to agree, it has proved very gratifying results. In my practice, by far the largest number receiving benefit from it have been children. Those who have, previous to their illness, been accustomed, to some extent, to a "fish diet," will be more likely to digest the oil, and more notably so in cold climates. Still the innumerable efforts that have been made in the shape of "pure cod-liver oil," "palatable cod-liver oil," "cod-liver oil with pepsin," "cod-liver oil with pancreatin," "cod-liver oil emulsions," etc., and so on, *ad infinitim*, attest the fact that the great *desideratum* after all is to render cod-liver oil capable of retention by the stomach, and digestable when it is retained.

As hydroleine is partially digested oil, and this partial digestion was brought about by a combination of factors suggested by actual physological experiments, these facts commend it to my confidence, and a trial of the preparation in seven typical cases convinces me that it possesses a high degree of merit, and I feel like it is a duty incumbent upon me to call the attention of my medical brethren to the subject.

The first case in which I prescribed it was that of a married lady 28 years of age, a blonde, and the mother of four children, the eldest 9, and the youngest 1 year old. From the birth of this she dated her illness, for she made a tardy convalescence, remaining unable to walk for a month. Soon after she began to grow weaker, and soon resumed her bed, which she had not left to any extent ever since, not at any time being able to sit up longer than fifteen or twenty minutes. During all the while she was under charge of a skillful physician. He had tried many remedies to check the rapid emaciation; among these were several different brands of malt extract, cod-liver oil, and various mixtures of the oil. None of the oils and their mixtures agreed with her. In March, I was called and prescribed hydroleine, a bottle of which I delivered at the time, directing her to commence with teaspoonful doses, to be gradually increased to twice the amount. It agreed with her finely, and by the time the first bottle was used she was very greatly improved. She procured and used two additional bottles, and, at this writing, June 15th, is considerably well.

The above case was one of general and persisting emaciation, unaccompanied by any cough or perceptable thoracic trouble. The ensuing case was one of diagnosed.

TUBERCULAR PHTHISIS.

The patient, a married lady, æt. 32, had been married about 14 years, and was the mother of six children, the youngest two years of age. Several of her sisters had died of the disease. Her medical adviser prescribed cod-liver oil, and she had taken a full dozen bottles with plenty of whiskey. The oil had not been digested, although it had been retained by the stomach. Her cough had grown constantly worse, and she grew rapidly weaker, week by week. I prescribed hydroleine for her, and she commenced to take it in April, about the 15th. It agreed with her finely. She rapidly gained weight and strength; her cough improved and has now nearly ceased. She has used nearly four bottles, and continues to use it, though apparently well.

I have prescribed it in three other cases, in two of which the results have been equally gratifying, but in the other case it produced nausea and greasy eructations.

From these trials I am led to think quite favorably of the hydrated oil, and am led to believe that, although it may not agree with all, it will be found of great and permanent benefit to a very large per cent. of consumption and other "wasting" diseases, and that it is destined, at no distant day, to very largely supplant the undigested oils.

# HORLICK'S FOOD

—FOR— —AND—

## INFANTS INVALIDS

*Not Farinaceous.* *Entirely Soluble.*

After a trial of **six** years, this unrivalled preparation has fully proved itself to be the best article of diet for Infants and Invalids.

**IT IS THE BEST SUBSTITUTE FOR MOTHERS' MILK,**

And has received the endorsement of the leading Physicians of this country and Europe, amongst whom we refer, by permission, to the following eminent medical men who have used it extensively in their practice:

**Prof. J. LEWIS SMITH, Prof. WM. H. BYFORD, Prof. J. P. OLIVER, Prof. H. O. MARCY,**
**" DE LASKIE MILLER, " J. ADAMS ALLEN, " A. J. GAWNE, &c., &c., &c.**

**Price, 18-ounce bottle, 75c.; 8-ounce bottle, 40c.**

## DRY EXTRACT OF MALT.

Warranted free from any adulteration whatever. Made with the utmost care from selected Canada barley malt, possessing many advantages over the liquid extracts. It will not ferment or undergo any changes. It is entirely soluble.
**Price, 18-ounce bottle, $1.00; 8-ounce bottle, 50 cents.**

MANUFACTURED BY

**J. & W. HORLICK & CO., Racine, Wis.**

***Wholesale and Retail Agent:*** ***London Agents:***
**OSCAR KRESS, 1670 Broadway, New York. F. NEWBERY & SON, 37 Newgate St., Lond., E. C., Eng.**

SOLD BY DRUGGISTS EVERYWHERE.

**A Sample Bottle of the above Preparations sent FREE to Physicians on application.**

☞ **Please mention MEDICAL RECORD.**

REED & CARNRICK, 196 Fulton Street, New York, will forward to any physician in the U.S., who will pay express charges, *a one-pound bottle of Maltine, or any of its combinations*, provided they mention THE MEDICAL RECORD. See page 4.

☞ **See advertisement of W. H. Schieffelin & Co., page 3.**

## SCOTT'S EMULSION PURE COD LIVER OIL,

With Hypophosphites of Lime and Soda. Perfect, Permanent, Palatable.

The well-known virtues of this preparation, that has now been before the profession for a number of years, hardly requires comment from us. But we desire, for the information of those whose attention may not have been directed to it, to present the following facts:

FIRST:—We use in the manufacture of our Emulsion, Cod Liver Oil that is prepared expressly for us, and is strictly pure, which is the most important consideration to the Physician.

SECOND:—By our process of Emulsifying, we so thoroughly incorporate the Oil with the Hypophosphite Salts, that the mixture is perfectly homogeneous, and remains in that condition without the slightest separation or change for years, unless exposed to the air or intense heat.

THIRD:—It is so palatable and easy of digestion, that it can be administered to children and persons with most sensitive stomachs without the slightest repugnance, and we are confident, from the results that have been obtained in the use of this preparation, and the flattering testimonials we have received from prominent physicians, that the proper manner of administering Cod-Liver Oil, even to patients that can tolerate the crude oil, is in the form of a palatable and easily digested Emulsion. There are some in the profession that adhere to the use of the plain oil; but, with all due deference, if they will make a trial of our Emulsion, we believe their prejudices will be removed, and they will find it much more beneficial to their patients.

With all the numerous Foods, Cereals, and so-called Constructive Agents of uncertain value that are being introduced, the physician must sometimes be at a loss to know what to prescribe. But we are assured that the profession will bear us out in the statement that in all Pulmonary troubles, especially where the lung tissue is involved, in Scrofulous children, and in Anæmic women of consumptive tendencies, as well as in general nervous debility, our combination will produce results, if properly administered, unequaled by any other preparation, and most satisfactory to the physician and patient. We most respectfully ask those who have never prescribed or seen its results, to give it a trial, and if you desire to make a personal inspection of it, we will be pleased to send a sample by express, prepaid.

FORMULA;—50 per cent. of pure Cod Liver Oil, 6 grs. of the Hypophosphite of Lime, and 3 grs. of the Hypophosphite of Soda to a fluid ounce. Emulsified with mucilage and glycerine.

**SCOTT & BOWNE, Manufacturing Chemists, 108 & 110 Wooster Street, New York.**

## SURGICAL REFLECTIONS AND ANATOMICAL OBSERVATIONS

### Bearing upon a Possible Course of the Bullet that Wounded President Garfield.

By FANEUIL D. WEISSE, M.D.,

NEW YORK,

PROFESSOR OF PRACTICAL AND SURGICAL ANATOMY, MEDICAL DEPARTMENT OF UNIVERSITY OF THE CITY OF NEW YORK.

On July 2, 1881, at 9.20 A.M., President Garfield received a pistol-shot wound from a British bull-dog revolver, which carried a $\frac{44}{100}$ central-fire cartridge (powder twenty grains, weight of bullet two hundred graihs). He was fired upon at a distance of eight feet (?). The incidents of the shooting were given (see *New York Herald*, July 3d, page 8) by a reliable eye-witness (Mr. Simon Camacho, Minister from Venezuela), as follows:

"I heard the noise of quick steps. The report of a pistol followed immediately. I turned quickly, and saw a man firing a second shot, into the back of President Garfield—directly in his back."

"What happened when he was hit?"

"Well, he fell—that is, he dropped or sank as it might be, and fell forward near the wall. His knees seemed to bend, and he leaned a little toward the right as he fell face downward."

"Did he speak?"

"No; not a word."

"Nor utter a word?"

"I heard none."

The *New York World*, of July 3d, states that the President pressed his hand against his side when wounded there, that hemorrhage occurred from the wound, and that as he fell he vomited.

Doctor Townshend, Health Officer of the District, is reported to have said: "I found the President, when I arrived at the Baltimore and Potomac Depot, about five minutes after the shooting occurred, in a vomiting and fainting condition. From the pulse at the wrist, I thought he was dying. I had his head lowered, and administered aromatic spirits of ammonia and brandy to revive him. This had the desired effect, and the President, regaining consciousness, was asked where he felt the most pain. He replied 'In the right leg and foot.' I asked him the character of his pains, and he said that it was 'a prickling sensation.'

"He rallied considerably, and I proceeded to examine his wounds. I found that the last bullet had entered his back about two and a half inches to the right of the vertebræ. I introduced my finger into the bullet wound, some hemorrhage followed. After examination of the wound, the President looked up and asked me what I thought of it. I answered that I did not consider it serious. He continued, 'I thank you, doctor, but I am a dead man.'"

The official bulletins from this time are here given:

EXECUTIVE MANSION, July 2, 1881.

12 M.—The President is somewhat restless, but is suffering less pain. Pulse, 112. Some nausea and vomiting have recently occurred. Considerable hemorrhage has taken place from the wound.

D. W. BLISS.

12.35 P.M.—The reaction from the shock of the injury has been very gradual. He is suffering some pain, but it is thought best not to disturb him by making any exploration for the ball until after the consultation at 3 P.M.

D. W. BLISS.

4 P.M.—The President's condition is somewhat less favorable, evidences of internal hemorrhage being distinctly recognized. Pulse 132; temperature, 96.8. That is a little below the normal. He suffers rather more pain, but his mind is perfectly clear.

D. W. BLISS.

WASHINGTON, July 2—11 P.M.

The President is resting quietly, and was cheerful. Pulse, 124; temperature, 99; respiration, 20. All the symptoms are favorable.

D. W. BLISS.

EXECUTIVE MANSION, July 3—1 A.M.

The improvement in the President's condition, which began early in the evening, has steadily continued up to this hour. His temperature and respiration are now normal, and his pulse has fallen to 120. The attending physicians regard all his symptoms as favorable, and a more hopeful feeling prevails.

D. W. BLISS.

EXECUTIVE MANSION, July 3—10 A.M.

The President has rested quietly and awakened refreshed, and his improving condition gives additional hope of his gradual recovery. Pulse, 114; respiration, 18; and temperature about normal.

D. W. BLISS.

EXECUTIVE MANSION, July 3—11 A.M.

The President's condition is greatly improved. He secures sufficient refreshing sleep, and during his waking hours is cheerful and is inclined to discuss pleasant topics. Pulse, 106: with more full and soft expression; temperature and respiration normal.

D. W. BLISS.

EXECUTIVE MANSION, July 3—6 P.M.

There is no appreciable change since the last bulletin. The President sleeps well at intervals. Pulse, 108; temperature and respiration normal.

D. W. BLISS.
J. K. BARNES.
J. J. WOODWARD.

EXECUTIVE MANSION, July 3—10.30 P.M.

The condition of the President is less favorable. Pulse, 120; temperature, 100; respiration, 20. He is more restless, and again complains of the pain in his feet.

D. W. BLISS.
J. K. BARNES.
J. J. WOODWARD.
ROBERT REYBURN.

EXECUTIVE MANSION, July 4—12.30 A.M.

The President's condition has changed very little since the last bulletin. Pulse, 112; temperature, 99.8; respiration, 20. Some tympanites is recognized. Does not complain so much of pain in the feet.

D. W. BLISS.
J. K. BARNES.
J. J. WOODWARD.
ROBERT REYBURN.

EXECUTIVE MANSION, July 4—8.15 A.M.

The condition of the President is not materially different from that reported in the last bulletin (12.30 A.M.) He has dozed at intervals during the night, and at times has complained of the pain in his feet. The tympanites has not sensibly increased. Pulse, 108; temperature, 99.4-10; respiration, 19.

D. W. BLISS.
J. K. BARNES.
J. J. WOODWARD.
ROBERT REYBURN.
FRANK H. HAMILTON.
D. HAYES AGNEW.

EXECUTIVE MANSION, July 4—8.15 A.M.

We held a consultation with the physicians in charge of the President's case at seven A.M. to-day, and approve in every respect of the management and of the course of treatment which has been pursued.

FRANK H. HAMILTON, of New York.
D. HAYES AGNEW, of Philadelphia.

July 5th.

8.30 A.M.—The President has passed a comfortable night, and his condition this morning is decidedly more favorable. There has been no vomiting since last evening at 8 o'clock, and he has been able to retain the liquid nourishment administered. There is less tympanites, and no abdominal tenderness, except in the wounded region. Pulse, 114; temperature, 100.5; respiration, 24.

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBERT REYBURN.

10 A.M.—The following dispatch has been sent by the surgeons in charge, to Doctors Agnew and Hamilton, the two consulting physicians:

EXECUTIVE MANSION, July 5—9.30 A.M.

After you left, the urgent symptoms continued; there was much restlessness, constant slight vomiting, and by 8 o'clock P.M. the President's condition seemed even more serious than when you saw him. Since then the symptoms have gradually become more favorable. There has been no vomiting or regurgitation of fluid from the stomach since 8 o'clock last evening.

The President has slept a good deal during the night, and this morning expresses himself as comparatively comfortable. The spasmodic pains in the lower extremities have entirely disappeared, leaving behind, however, much muscular soreness and tenderness to the touch. There is less tympanitis, and no abdominal tenderness whatever, except in the hepatic region. Since 8 P.M. he has taken an ounce and a half of chicken broth every two hours, and has retained all. The wound was again dressed antiseptically this morning. Altogether, but one-half a grain of morphia has been administered hypodermically during the last twenty-four hours, and it has been found quite sufficient. His pulse, however, still keeps up. At 8.30 A.M. it was 114;

temperature, 100.5; respiration, 24. Seventy-two hours have now elapsed since the wound was received. We cannot but feel encouraged this morning, although, of course, we do not overlook any of the perils that still beset the path toward recovery. The course of treatment agreed upon will be steadily pursued.

D. W. BLISS,
J. K. BARNES,
J. J. WOODWARD,
ROBERT REYBURN.

12.30 P.M.—The favorable condition of the symptoms reported in the last bulletin continues. There has been no recurrence of the vomiting. Pulse, 110; temperature, 101; respiration, 24. The President lies at present in a natural sleep. No further bulletins will be issued till 8.30 P.M., unless in case of an unfavorable change.

D. W. BLISS.
J. K. BARNES.
J. J. WOODWARD.
ROBERT REYBURN.

Besides these official bulletins, it had been stated, prior to July 4th, that the wound was located between the tenth and eleventh ribs, four inches to the right of the median line of the back; that a finger introduced into the wound had felt that the eleventh rib was fractured; that at another exploration the finger had felt the substance of the liver; that a probe had been passed in a distance of three inches. By the two latter examinations the direction of the wound was found to be downward and forward.

On July 4th I made a careful analysis of the symptoms that had presented up to that date, with the following result:

*First.*—A pistol-wound was located between the tenth and eleventh ribs, four inches from the median line of the back.

*Second.*—Upon receipt of the wound the President fell, or rather sank down to the right, not losing consciousness.

*Third.*—Vomiting occurred as he fell, which had continued from time to time.

*Fourth.*—Within five minutes alarming failure of heart's action occurred.

*Fifth.*—Immediate pain of right leg and foot, of the nature of a prickling sensation.

*Sixth.*—Hemorrhage from wound, though not excessive.

*Seventh.*—Lowering of the temperature to 96.8° during shock.

*Eighth.*—Equable, almost normal standard of respiration.

*Ninth.*—Pulse fluctuations from slight causes.

*Tenth.*—Pains in legs and feet.

*Eleventh.*—Slight tympanites.

*Table of seventy-four hours from receipt of wound.*

| | | TEMP. | PULSE. | RESP. |
|---|---|---|---|---|
| July 2d, | 9.25 A.M..... | — | Almost pulseless. | — |
| " | 4 P.M..... | 96.8 | 124 | — |
| " | 11 P.M ..... | 99 | 124 | 20 |
| July 3d, | 1 A.M..... .... | Normal. | 120 | Normal. |
| " | 10 A.M..... . | Normal. | 114 | 18 |
| " | 11 A.M ..... | Normal. | 116 | Normal. |
| " | 6 P.M..... ..... | Normal. | 108 | Normal. |
| " | 10.30 P.M..... | 100 | 120 | 20 |
| July 4th, | 12.30 A.M..... | 99.8 | 112 | 20 |
| " | 8.15 A.M..... | 99.4 | 108 | 19 |
| July 5th, | 8.30 A.M..... | 100.5 | 114 | 24 |
| " | 12.30 P.M..... | 101 | 110 | 24 |

Negative evidence existed which seemed to exclude injury having been inflicted to either of the following parts:

*First.*—An artery or vein of any considerable size.

*Second.*—The pleura, or lung.

*Third.*—The diaphragm (at a point where it is covered by pleura or peritoneum).

*Fourth.*—The right kidney.

*Fifth.*—The spinal cord.

*Sixth.*—The ascending colon, where not covered by peritoneum.

From the President's good general condition up to that time, there appeared a chance that the peritoneum and the organs invested by it—liver, stomach, small intestine, large intestine, and spleen—had escaped injury.

Of the symptoms developed up to July 4th, the fifth and tenth seemed to point to an injury of the right sacral plexus, as the area of distribution of the right great sciatic nerve was the first location of the pains, etc., while the pains of the left leg and foot would seem to have been developed subsequently.

The third and fourth symptoms, in the light of the localizing ones just stated, become contributive in adding weight to the possibility.

It remained to determine how a bullet, entering where the President was wounded, could escape injuring the right pleura, the right lung, the diaphragm, the peritoneum, the liver, the right kidney, the ascending colon, the small intestine, or the spinal column, and the life of the wounded person be spared, by deflection of the bullet in such a peculiar way as to reach one or more of the nerves that contribute to the sacral plexus.

*It seemed to me possible that the bullet had penetrated the tissues superficial to the eleventh rib, impinged upon the rib with sufficient force to fracture it, which force was enough to turn the ball upon its axis, so as to point downward; thence it was deflected downward, forward, and inward; that it had pierced a subpleural portion of the diaphragm (if at all), passed to the anterior surface of the transversalis fascia, posterior to the convex external border of the right kidney, passed through the adipose tissue behind the kidney and ascending colon, following the curve, downward and inward, of the plane of the anterior surface of the muscle-wall of the lumbar region; that it had passed into the iliac fossa, upon the iliac fascia, the posterior part of which it traversed in a direction downward and inward, till it reached the psoas magnus muscle; that it either perforated or passed posterior to the psoas magnus muscle to reach the sacral plexus of nerves, the trunks of which, one or more, it wounded.*

The bulletins of July 5th strengthened my convictions that my theory had some ground of plausibility. To the symptoms which had developed up to July 4th, there had been added: 1st, muscular soreness of lower extremities; 2d, tenderness to the touch of the lower extremities. Of the symptoms of the 4th there had subsided: 1st, the vomiting at 8 P.M. on July 4th; 2d, the spasmodic pains of lower extremities; 3d, less tympanites.

On July 6th I determined to investigate, by actual dissection, the possible track of the wound, whether, anatomically, such a course could be taken by a bullet. I obtained a British bull-dog revolver and the No. 44 cartridges, to determine what kind of a wound of entrance the bullet would make in a human body, its penetrating power at a distance of eight feet, and how much diminution of force would be effected by impact upon bone.

I found upon examination that, as a weapon, its inherent defects were such as to make it one which lacked precision in firing, and diminished the force of the ball. That the cartridge also presented certain peculiarities, which, when it was fired, would tend to diminish its penetrating power and cause a great expenditure of its force upon impact upon any resisting surface.

I fired into a subject several times, and determined the wound of entrance and exit as both smaller than I expected.

*I would here say that no attempt was made to so fire as to repeat the wound inflicted upon the President—*

*that would be impossible—and then track the ball, so as to determine the course it had taken; nor was the attempt made to make the ball so penetrate as to take the possible course advanced.*

A few shots enabled me to obtain all the information I wanted, viz.: that a bullet from the British bull-dog revolver suffers a great expenditure of force by impact upon a bone; that at the instant of its impact it turns on its axis; that if its force is still sufficient to carry it on flatwise through the bone, it makes a large hole in it, splinters it, and carries the fragments before it into the tissues beyond; that if it simply fractures the bone, it is either deflected or stopped in its course.

At the point of wound the following conditions would favor the occurrence of deflection.

The eleventh is the most movable of all the ribs, being free at its anterior end and not steadied, as is the twelfth rib, by a muscle attached to its lower edge. The conditions favorable to deflection by impingement upon and fracture of this rib are: 1st, the mobility of the rib makes it like a hickory twig fixed at one end only, and its swaying upon impact would expend a good deal of the force of the ball; 2d, the external surface of the rib, being convex, tends to deflect a ball (of all bones of the body a rib probably deflects balls most often); 3d, if the eleventh rib is pushed inward from behind it rises anteriorly, and if a ball struck it with sufficient force to fracture it, it would be likely to turn the ball on its axis, and deflect it downward and inward, if already spent; 4th, the clothing of the President must also be considered as an element contributing to diminish the penetrating power of the ball before it reached the rib, but I have no data with reference to the clothing.

Had the ball been turned on its axis, and still had sufficient force for onward progression, it would have crashed through the eleventh rib, splintered it, and carried forward the fragments of bone directly into the viscera beyond. Deflected upward, it would have wounded the lung. Deflected forward along the rib, it might have passed into the abdominal parietes.

A well-developed subject, six feet high, was suspended so that the feet rested on the floor. A twelve-inch trochar, one-fourth of an inch in diameter was made to enter the cadaver exactly at the point of the President's wound, penetrating at a right angle. The object of this was to pin the tissues and organs together, so as to steady them during the progress of dissection. Skin incisions, to include the area of the injured region, were made as follows: The first from the median line to the side, at the level of the upper border of the tenth rib; the second from the median line outward, below the level of the crest of the ilium; the third along the median line of the back united the two internal extremities of the transverse incisions. The flaps of tissue were turned off to the right side of the body. The layers in the track of the trochar were found superposed upon, and were removed in the following order, down to the plane of the ribs: skin, subcutaneous tissue, latissimus dorsi muscle plane, and that of the serratus posticus inferior muscle. The external longitudinal half of the dissection region presented the exterior surface of the tenth, eleventh, and twelfth ribs, and their intervening muscles; below the twelfth rib, between it and the crest of the ilium, the exterior surface of the posterior portions of the abdominal muscles. The internal longitudinal half of the dissection region included the mass of the erector spinæ muscle (sacro-lumbalis and longissimus dorsi portions, in order, from the external limit of the muscle-mass to the spines of the vertebræ), covered by the posterior layer of the lumbar aponeurosis.

The external intercostal muscles were dissected out of the tenth and eleventh intercostal spaces, and the tenth and eleventh intercostal nerves, arteries, and venæ comites were respectively seen running parallel with the lower border of the ribs, the vessels and nerve were close to the tenth rib; and about a quarter of an inch from the border of the eleventh. The costal layer of the pleura filled the tenth and eleventh intercostal spaces, passing to the interior surfaces of the ribs.

The costal layer of the pleura was separated from the eleventh rib for about an inch, corresponding, as near as could be inferred, with the point of fracture of the President's rib, an inch of the rib was then exsected with the bone-forceps. The pleural cavity was now opened, and some contained fluid escaped. The finger was introduced into the pleural cavity downward, so as to determine how low the sac of the pleura descended; a distinct pocket of pleura was found down to the level of the twelfth rib, the bottom of the pocket corresponded with the centre of the twelfth rib, the bottom of the cavity rising toward the spine posteriorly and springing from the tip of the twelfth rib on to the interior surface of the eleventh rib, anteriorly. The contour of the liver was now appreciable, as it obstructed the opening in the chest-wall, covered by three planes of tissue, which were dissected through: 1st, the diaphragmatic layer of the pleura; 2d, the right portion of the diaphragm; 3d, the peritoneal lining of the diaphragm. Opening the peritoneum at the side of the penetrating trochar, the thick lateral superior border of the right lobe of the liver obtruded. Dissecting the diaphragm away from the interior of the eleventh rib, and below it, the superior external border of the right kidney presented, without meeting with pleura or peritoneum.

A large director was passed in the eleventh intercostal space, below and on a line with the fixed trochar, so as to reach the anterior surface of the transversalis fascia without perforating the pleura, peritoneum, or diaphragm (except at a point where the latter is not invested by pleura and peritoneum). As the director passed downward, it followed the plane and curve of the loin forward and inward. The twelfth rib was cut through with bone-forceps opposite the external limit of the erector spinæ muscle-mass, and dissected out, carrying away the attachment of the diaphragm and other muscles to it. The planes of the muscles of the abdominal wall below the twelfth rib were incised through, along the line of the director down to the crest of the ilium. The twelfth intercostal nerve superficial to the plane of the transversalis muscle was seen; in the plane interior to the transversalis muscle, the ilio-hypogastric and ilio-inguinal nerves were dissected out, and seen to run parallel with the crest of the ilium and around the side. The hand was now passed into the superior portion of the opening, through the abdominal wall, onto a mass of fat which lies behind and along the external convex border of the kidney, and opposite the longitudinal sulcus, where the peritoneum is reflected from the anterior surface of the kidney to the interior of the abdominal wall at the external longitudinal limit of the lumbar region.

The fingers and palm of the right hand—standing at the left of the subject as they were introduced—entered at the upper part of the incision made along the director, and touched the fat at the border of the

right kidney, and the sulcus where the sac of peritoneum passes from the anterior surface of the right kidney to the parietes of the abdomen, at the side wall of the abdomen. Insinuating the fingers between the lips of the incision through the parietes, to the anterior surface of the transversalis fascia, the back of the fingers lay upon the transversalis fascia, and their palmar surfaces impinged upon the fat and areolar tissue behind the kidney and the ascending colon anteriorly—where the colon is not covered by peritoneum. Crowding the colon forward, the external lateral reflection of the peritoneum (external fold of ascending meso-colon) from the external side of the ascending colon to the abdominal parietes will be appreciated, and can be readily separated from the transversalis fascia.

Just above the crest of the ilium, near the external psoas magnus, recognizing the anterior crural nerve, and beyond it the obturator nerve, the lumbo-sacral cord of the sacral plexus, and even the anterior surface of the sacral plexus, and pyriformis muscle may be appreciated. With the fingers thus crowded into the pelvis the internal iliac artery and its branches with their venæ comites were pushed forward toward the median line, carrying fascia before them.

A second subject was suspended and another dissection was made, from which it was intended to obtain a drawing of the contained organs, and which is given. (Figure 1.)

Figure 1 is a photo-engraving of the drawing, and the illustration is correct, with the exception that the weight of the liver has caused it to fall a little lower than normal, carrying the kidney with it, and likewise the diaphragm.

*Fig. 1*

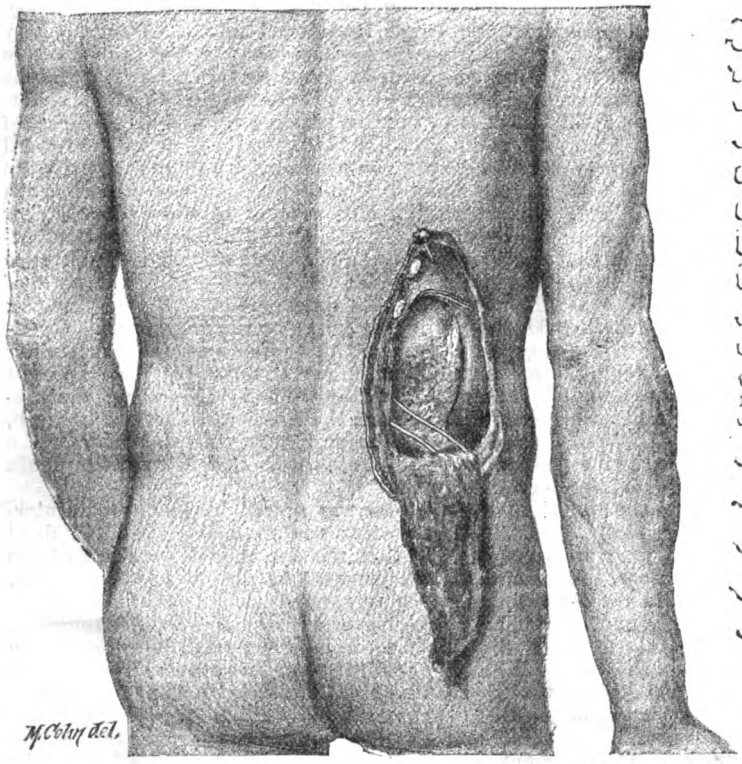

*Fig. 2*

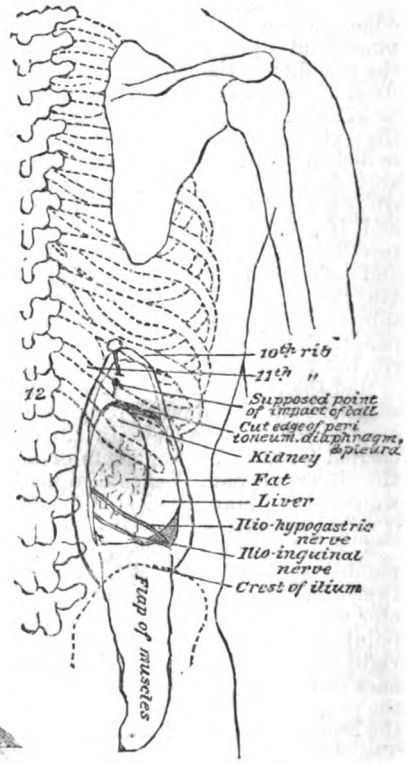


limit of the erector spinæ and quadratus lumborum attachments to the crest of the ilium it is, that the ilio-hypogastric and ilio-inguinal nerves pass from the anterior surface of the quadratus lumborum muscle onto the transversalis muscle, between it and the transversalis fascia. From this point the fingers slid readily into the iliac fossa over the middle of the crest of the ilium; the palmar surfaces of the fingers upon the iliac fascia, the nail surfaces crowding against the cæcum of the large intestine, where the same is not covered by peritoneum. The peritoneum is reflected from the sides of the cæcum to the wall of the iliac fossa—the meso-cæcum.

The fingers may pass on easily to the external surface of the psoas magnus muscle, where a sulcus presents between the latter muscle and the iliacus internus muscle; tearing through the fascia, which bridges from one muscle to the other across the sulcus, the fingers may be insinuated behind the

Figure 2 is a schematic key of figure 1. In it the fall of the liver has been corrected; the spot of supposed impact of the ball on the eleventh rib should, I think, be nearer the centre of the bone. The steps of this dissection were as follows:

*First.*—A glass headed pin about five inches long, was entered in the tenth intercostal space, four inches from the line of the spinous processes of the vertebræ (the spot was confirmed by Prof. Hamilton, as the point corresponding to which the bullet entered the President's body); the pin was entered at a right angle, to fix the parts only, having no reference to the course of the ball.

*Second.*—A triangular flap, including all the layers from the skin to the plane of the ribs was made, with its apex on the tenth rib above the penetrating pin; the lateral incisions of the compound flap was turned downward on to the gluteal region.

*Third.*—The eleventh and twelfth intercostal mus-

cles were dissected as far as they were exposed out of the tenth and eleventh intercostal spaces.

*Fourth.*—The vessels and nerves of the tenth and eleventh intercostal spaces were recognized and cut away.

*Fifth.*—An exsection was made of an inch of the eleventh rib at its supposed point of fracture.

*Sixth.*—The oblique line of the reflection of the pleura from the costal wall on to the diaphragm was appreciated and then cut away.

*Seventh.*—Exsection of the twelfth rib outside of the erector spinæ muscle was made.

*Eighth.*—The posterior portion of the abdominal muscles was cut away, recognizing the twelfth intercostal vessels and nerve exterior to the transversalis.

*Ninth.*—The ilio-hypogastric and ilio-inguinal nerves were dissected out, and preserved in situ; in the plane between the transversalis muscle and the transversalis fascia.

*Tenth.*—The layers upon the superior convexity of the liver were recognized in their order: pleura, diaphragm, and peritoneum.

*Eleventh.*—The peritoneum was opened and the thick superior portion external border of its right lobe recognized.

*Twelfth.*—The fat posterior to the kidney was appreciated and partly dissected away to bring the kidney into view.

*Thirteenth.*—The peritoneum was slit along the external border of the right lobe of the liver, and the reflection of the peritoneum from the external border convexity of the kidney to the abdominal parietes was seen, as it comes out from the anterior surface of the kidney.

On the morning of Thursday, July 7th, I called upon Professor Frank H. Hamilton, M.D., and stated to him my theory of the possible deflection and course of the ball, giving him my reasons therefor. I then asked him to give me a detailed statement of all the facts in the case at the time of his visit to Washington. This he kindly gave me, and, among other symptoms, stated that the President had called attention to a peculiar sensitiveness of the skin of the right side of the scrotum. An injury to the ilio-hypogastric and ilio-inguinal nerves, which lie in the supposed track of the ball, according to the theory advanced would account for this peculiar sensation. Injury to the sacral plexus would also account for it. Encouraged by Professor Hamilton, I repeated my dissections on July 7th, and he made an appointment to be present at a demonstration of the same on the following day. On July 8th, I obtained several cadavers resembling the physique of the President, and at two P.M., in the presence of Professor Frank H. Hamilton, M.D., Dr. George F. Shrady, and other professional gentlemen, I repeated the dissections, pistol-firing, etc.

The following letter explains itself:

My Dear Doctor—I have from the first sought to encourage you in your present line of study; not because I had by any means determined in my own mind the course of the bullet, but because it seemed proper to determine anatomically all the possibilities in the case. I also encouraged you to give your results to the profession through the secular press, in order that they might more promptly be subjected to the criticism or approval of medical men. Yours truly, FRANK H. HAMILTON.

July 11, 1881.

A special application of the above anatomical observations to the appreciation of the President's wound must take into consideration his peculiarly robust physique.

The mass of fat located on the anterior surface of the posterior portion of the transversalis muscle and the quadratus lumborum muscle is probably, in the President's body—judging from his physique as pictured and described—from one and a half to two inches thick. This fat is continued, to a certain extent, in such a well-nourished organization, into the iliac fossa as well.

Given a bullet that has, by impact upon and fracture of the right eleventh rib, been deflected downward and forward into this layer of fat behind the external border of the right kidney, it is not difficult to conceive how, with its already expended force of progression, it could continue in the direction of least resistance through the adipose tissue, taking the inclined curve downward and inward of the anterior surface of the muscle-mass of the lumbar region into the iliac fossa; perforate the fascia in the sulcus between the iliacus internus and psoas magnus muscles; or perforate the latter muscle, and so reach the lumbo-sacral cord, or one of the sacral nerves in the right half of the pelvis, and thus inflict more or less injury to one of the contributing trunks which form the sacral plexus.

Here I would state that it was repeatedly observed by myself, and verified by Prof. Hamilton and Dr. Shrady, that a finger on the sacral plexus could be felt by rectal examination.

The fact that the ilio-hypogastric, and ilio-inguinal nerves—usually the latter—distribute to the scrotum, and that they cross the possible track of the bullet, presents a most important element in the anatomical solution of the case. It will also be remembered that the skin of the scrotum is supplied from the sacral plexus by the perineal branches of the pudic and inferior pudendal branch of the lesser sciatic.

A difficult anatomical point to determine presents in the case of fracture of the eleventh rib, viz.: to appreciate the oblique line of pleural reflection from the costal wall to the diaphragm from behind upward and forward.

Had it been the twelfth rib that was fractured, there would be no difficulty in eliminating the inferior limit of the reflection of the pleura from the diaphragm, in case of deflection downward and forward.

For the purposes of this case we must consider the diaphragm as divided into a pleural and subpleural portion, relative to the line of reflection of the pleura from the circumference of the arched thoracic base to the superior surface of the diaphragm.

A man of the robust physique and ample chest of the President has a powerful diaphragm, with a large mass of sub-pleural muscular structure posteriorly. He has a large, heavy liver. His lungs are in a constant state of distention, amounting to that of full inspiration of a less powerful physique. The upper edge of his right kidney is probably on a line with the lower border of his eleventh rib.

In walking, the weight of his liver would hang forward away from the posterior wall and still further tend to depress the diaphragm and increase the thickness of its subpleural portion.

In walking his pleural reflection opposite the vertical line of the bullet-wound would be at the eleventh rib, to the median line side of the wound of entrance.

# A NEW CURRENT OF INDUCTION ELECTRICITY;

## Or, a New Method of Producing Electrical Nerve and Muscle Reactions.*

By WILLIAM J. MORTON, M.D.,

NEW YORK,

PROFESSOR DISEASES OF THE MIND AND NERVOUS SYSTEM, UNIVERSITY OF VERMONT; PHYSICIAN TO DEPARTMENT FOR NERVOUS DISEASES, METROPOLITAN THROAT HOSPITAL; MEMBER NEW YORK ACADEMY OF MEDICINE, ETC., ETC.

In a paper on Statical Electro-therapeutics or Franklinism, read before the New York Academy of Medicine, March 3, 1881, and printed in the New York Medical Record of April 9th, I stated that an induction current could be obtained from the frictional induction electric or Holtz machine, and that this current produced nerve and muscle reactions similar to those produced by the induction currents now in common medical use under the general designation of faradism.

This current I claimed to be novel, probably, to the physics of electro-statics, and certainly to medical practice. After the reading of the paper, the very simple manner of producing the current from the Holtz machine, and its reactions, in the persons of many members of the Academy were demonstrated, and it was generally conceded that, as compared with the ordinary induction currents now in use, the static-induced, as I ventured to name it, produced maximum muscular contractions with a minimum amount of pain.

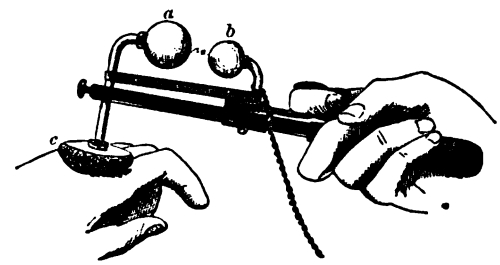
The object of the paper referred to was to call attention to the neglected claims of frictional electricity, or franklinism, as produced from the Holtz machine and its modifications, in the treatment of disease, an object toward whose attainment I felt the more impelled, since there existed at the time in American medical literature no treatise or publication to which the physician could apply for guidance and information on the subject. For, though of sporadic instances of the individual medical use of statical electricity there were doubtless many instances, no systematized effort at its introduction into practice had been made.

It is gratifying to note the interest in the matter that has now sprung up. Many electrical machines of a variety of patterns have been ordered of the makers, and we may soon expect to hear reports for and against the revived method.

Having, then, already elsewhere treated somewhat fully the general subject of statical electricity in its medical applications, I have nothing further to add until the experience of others comes forward to criticism.

In the meantime the only element of strict novelty in the revival of franklinic electricity is the induction current referred to, which places in the hands of the practitioner in the same machine, as I shall point out, both franklinic and faradic electricity. For this reason of novelty, as well as on account of the intrinsic interest and worth of the current to neurologists, I wish to emphasize, and to present the subject briefly to the members of the association.

Very soon after I began the study of the medical properties of statical electricity, my attention was struck by accidentally receiving from the conductors of the machine, a thrilling sensation and contraction of the muscles, which exactly recalled the ordinary faradic current. Following out the clue thus gained, I constructed a new electrode for obtaining muscular contractions at any given point, by means of the spark, while yet not allowing the spark to come in contact with the skin. This electrode I will describe briefly. Its main principle rests in the fact that if two statical and sustained potentials in the act of discharge are interrupted in the circuit by a series of spark discharges, the effect upon muscular fibre in some remote part of the current removed from the spark discharge is to be thrown into contraction. The accompanying cut illustrates the mechanical construction of the electrode. Sparks of a desired and given length between (*a*) and (*b*), the distance between which may be regulated at will, cause muscle and nerve reactions beneath (*c*), a wet sponge. The patient in this instance is not insulated.



I used this electrode for some time to avoid the pain of the sparks administered to children and timid subjects. But it soon became evident that the physiological effects of the spark and of the current thus interrupted were not identical, and I finally restricted the use of the electrode to those cases in which I had previously used the faradic electrodes, as, for instance, in exciting individual muscles, as in Bell's and other paralyses.

The more I used the electrode the more striking became the principle involved, and I proceeded with various experiments which I will not detail. The nearest approach to final success was an adjustable break in the circuit of the ordinary conducting wires held in the hand and connected with the two condensers of the machine. This caused merely a series of heavy, jerking discharges, and corresponding contractions, far from the smooth current desired. I next attached one conducting wire and electrode to the inside of one jar, and the other to the outside of the second jar, producing in this way a very fair resemblance to the faradic current. Finally, the effect desired, viz., a smooth and agreeable current, producing strong muscular contractions, was at last secured in a manner as simple as efficacious. It is as follows: We remove the connecting-bar or chain between the two *outer* coatings of our Leyden-jars, connect our conducting-wires, armed at one end by a small hook or by a clasp, to each outer coating respectively, and finally, connect as usual the two inner coatings by the discharging-rod or rods. The subject or patient now takes hold of the two electrodes, not requiring, of course, to be insulated. As soon as the machine is set in motion and electricity generated, the discharging-rod or rods may be drawn out a very small fraction of an inch, and at once a current is felt between the two sponge-electrodes, which, in its general characteristics, cannot be distinguished from the ordinary faradic current. This current I have ventured to call the static-induced current. The muscles to which it is applied at once

* Read at the annual meeting of the American Neurological Association, New York, June 16, 1881.

spring into energetic contraction. The response, I am persuaded, is quicker than that evoked by the induction currents in general medical use. Supposing, as experiments show, the time usually occupied by a muscular contraction is about one-twentieth of a second, preceded in each instance by a latent period, it would appear with the static-induced current that the latent period is curtailed, while at the same time Hallerian irritability is more rapidly evoked. This is a point, however, which could only be determined by careful experiments in the physiological laboratory. The obvious deduction in practice is that, in cases where it is of diagnostic value to determine early loss of faradic excitability, this can be done by very delicate currents of the static-induced. It is then a delicate test for the state of muscular irritability.

This current is, furthermore, soft and agreeable, and produces no shock. As has been said, it produces a maximum of muscular contraction with a minimum amount of pain. A comparison with the sensations experienced from a Rumkorf coil, a magneto-induction apparatus, or an ordinary galvano-faradic instrument, amply sustains this assertion. In treating children, the painless character of the current is an important consideration. Another peculiarity of the current is its high tension, indicated by its disposition to jump from the conducting-wires in the form of fine prickling sparks. To prevent this—disagreeable alike to physician and patient—it is necessary to have the conducting wire or chain well insulated from the sponge upward. My electrodes are made with glass tubes for handles, while the wires are encased in ordinary black rubber tubing.

The strength of the current may be regulated to a nicety by means of the discharging-rod or rods, ranging from an almost imperceptible tingle up to extreme and rigid flexion of the arms, should, for instance, the electrodes be held in the hands. To be obtained at its best, the electric machine must be generating a considerable *quantity* of electricity. If this is not the case, the tension at the same time remaining high, a "jerky" character in the current becomes evident.

The static-induced current will not, of course, be confounded with the series of discharges taking place between the inner coatings of the jars. This latter, in silent current forms, produces no muscular contractions or sensations of any kind. In repeated discharges, caused by an interruption in the circuit, it is too painful to be borne.

The modification in the manner of producing the muscle and nerve reactions thus far described, by means of the static-induced current, by connecting one conducting wire and electrode to the *inside* of one Leyden-jar and the other to the *outside* of the second jar, has been already referred to. Thus produced, the current is not as smooth as when taking its sources from the outside of both Leyden-jars, but this method may be pursued if desired.

The rationale of the term static-induced current and of its production would seem to be this: It is static, because its source is static electricity, just as we say, galvanic induction electricity. It is induced because the outer coatings of Leyden-jars are electrical by induction in the same manner as the secondary coil is electrical. The inside of the jar may be said to correspond to the battery current of an induction coil—the outer coating to the secondary current. It is a current because it is an equalization of two potentials along a conductor, as in a galvanic current, where we have a + and a — potential. And to carry the analogy to the secondary current of an induction coil further, the interruptions at the discharging-rod in spark form may be said to correspond to the interrupting hammer of the faradic apparatus. Each spark causes a rise and fall of potential in the interior of the two Leyden-jars, and, as a consequence, a corresponding rise and fall in the induction of the outer coating. We have thus two supplies or potentials of opposite induction electricity on the outer coatings, and with each spark as many waves or induction impulses, whose strength is determined by the strength of the spark, that is to say, by the amount of the discharge permitted between the insides of our two Leyden-jars.

This, then, is an entirely new current in medicine, and it is not a little curious that, with all the experience with frictional machines, it should have remained undiscovered up to the present day. The three main methods of administration of static electricity up to the time of the publication of my paper were by insulation, by sparks, and by shocks; the new current adds a fourth, which greatly widens the scope of medical statical apparatuses, for by the simplest of arrangements the frictional machine is converted into a machine which will do all the work of the best faradic machine.

We thus have at command in a frictional machine all of faradism, in addition to the static electricity; for working purposes we have all the advantages of both systems. We have, moreover, a current superior to the faradic currents in use, in that it produces the muscle and nerve stimulation with a far less amount of pain. The new current, then, has a record yet to make, and I venture to hope that it may have a therapeutic future.*

15 East Forty-fifth Street, June 13, 1881.

---

Inunction as a Remedy for Local Inflammation.—Dr. Edward T. Williams, in a letter to the *Boston Medical and Surgical Journal*, highly recommends the old-fashioned remedy of applying oil or grease externally for acute inflammations. He has used it for years, and finds it a very efficient substitute for a poultice. In almost all forms of acute inflammation of the thoracic and abdominal viscera, also in inflammatory sore-throat, abscesses, and some cutaneous eruptions it is very valuable. He generally orders lard, which is to be found in every household, simply rubbed upon the skin and covered over with a piece of flannel. If a stimulating effect is wanted, he adds a little salt, when the mixture answers as well as camphorated oil.

---

* It has often been noted, that in the presentation of novel subjects, a number of minds have been working in the same direction, while in this unconscious race he who first struggles to the goal of publication wins the title of priority. This seems to have been true of the little current and its reactions I have described. For, having given it forth in full in my paper of March 3d, I was both surprised and gratified to find that our distinguished president had also been going over the same ground and had embodied his results in his very valuable t eatise on Medical Electricity, issued in May last. I can best refer to this unexpected and to me very agreeable corroboration of my results by quoting from Dr. Bartholow's letter to the New York Medical Record of May 7th:

"In the last three issues of your valuable journal have appeared very interesting communications from Dr. William J. Morton, of New York, on the subject of the Holtz Electrical Machine.

"In his first paper he anticipated me in the publication of observations on the Holtz Machine, which will appear in my Treatise on Medical Electricity, the printing of which has been completed and is now in the binder's hands. At the last moment I was able to append a note to the preface, calling attention to the appearance of Dr. Morton's paper on the subject, which I had announced as novel."

I do not need to refer to the courtesy which dictated this prompt acknowledgment from Dr. Bartholow.

It is certainly extremely satisfactory to find from thus eminent authority this independent confirmation of results, which I had already thought worth while bringing to the notice of the profession.

## A CASE OF
## FOREIGN BODY IN BLADDER—MODIFIED LATERAL LITHOTOMY.

By F. E. AINSWORTH, M.D.,
ASSISTANT SURGEON, UNITED STATES ARMY.

H. W. H——, aged fifty, born in Massachusetts, single, and by occupation a miner, was admitted to the Hospital of the Sisters of St. Joseph, Prescott, A. T., on April 14, 1880, with symptoms of vesical calculus. The following history was elicited from him: He had been a masturbator from boyhood, and during all this time had been in the habit, more or less frequently, of introducing straws or long stems of grass into the penis for the purpose of provoking an erection and producing the sexual orgasm. This practice continued without accident or ill effects so far as he could discover, until 1852 or 1853, when, while using a large straw in his customary manner, a portion about five or six inches in length was broken off within the penis, and during his subsequent efforts to extract it, slipped or was forced into the bladder. He felt no inconvenience afterward and was able to pursue his avocation, that of a farm laborer, uninterruptedly. Several weeks after the introduction of the foreign body, while he was straining at stool, it entered the urethra and was, with a great deal of pain and difficulty, expelled; it was encrusted with calculous deposit, and, patient avers, was increased to a size larger than that of a lead pencil. No further symptoms arose, and, undoubtedly, as he says, the calculus and its nucleus, were wholly evacuated. Not deterred by this accident, he continued his practice, with no effect perceptible to himself, except the pleasurable sensation produced at the moment, until November, 1879, a period of nearly thirty years. In November last he introduced as he had often done before, a large hollow straw, or grass stem, into which, for additional security, he had thrust a smaller stem, thus filling up the canal, and rendering the straw stiffer and less liable to break. On attempting to withdraw the two, however, the inner stem, which during his manipulations had probably become projected into the cavity of the bladder, beyond the extremity of the outer stem, was gripped at the vesical neck, or in the urethra, and was left behind as the outer one was withdrawn. His subsequent attempts to reach and remove it, which were made with a blunt iron wire, were futile, and at last the straw slipped entirely beyond his reach, into the bladder undoubtedly.

For two or three weeks he had no trouble whatever, but at the expiration of that time he began to experience a constant desire to urinate, pain over the pubes and in the penis; urine thick, muddy, tinged with blood, etc. These symptoms steadily increased in severity until about the middle of February, when he passed with his urine, as he says, "about half a tablespoonful of gravel." No improvement in his vesical trouble followed, but he continued at intervals to void with his urine larger or smaller concretions, until March 15th, when he passed several much larger than the previous ones, three of which measure three-sixteenths of an inch each in diameter, and together one inch and a quarter in length. In each of the pieces, which are phosphatic in composition, can be seen the straw which formed the nucleus. The patient informed me that these three stones are only about one-sixth of what he passed at this time. The remainder he lost or threw away, but some of them were very much thicker and longer than these which he brought to me. Notwithstanding the escape *per vias naturales* of so large a quantity of calculous matter, he grew steadily worse, until he was obliged to discontinue his work, placer-mining. On April 12th he presented himself to me with the above history, and on April 14th was admitted to the Sisters' Hospital, which was under my charge. On admission the patient appeared to be a man of fairly good physique, but of decidedly weak intellect; complained of constant pain above the pubes, in the rectum, and running down into the penis; stream of urine sometimes free, but often suddenly stopping with acute agonizing pain, followed by passage of blood; pain during movement of any kind, especially riding. His urine was thick turbid, and offensive, containing gelatinous pus, mucus, and blood.

Passing a sound into the bladder, I at once detected a calculus, but further examination, as to the size, number, location, etc., was rendered very unsatisfactory because the organ would retain hardly an ounce of urine or injected water, and was intolerant of much manipulation. The finger in the rectum revealed considerable enlargement of the prostate. The patient was put on general treatment, and efforts were made to improve the condition of his bladder sufficiently to render the crushing operation practicable, but on June 5th, no progress having been made, I determined to perform the operation of lithotomy, which I did on the following day, June 6th. The patient was anæsthetized with ether, and in the presence of and with the assistance of Surgeon J. C. McKee and Surgeon A. K. Smith, U.S.A., and Drs. Lincoln and McCandless, of Prescott, I performed the lateral operation. The external incision was made in the usual manner, but after opening the urethra in front of the prostate, I barely nicked that gland, and then dilated it with my finger, as in the median method, intending, should the stone or stones prove larger than was expected, to enlarge the opening in the prostate by the bilateral incision, if need be, which, with the free external incision already made, would give abundant room for extraction. Fortunately the opening already made was sufficient. With a pair of small but very strong and sharply curved forceps I seized and extracted four calculi successively, two of which were encysted, and required to be freed from their bed by the scoop before extraction was possible. These stones are about three-eighths of an inch each in diameter, and together measure three and a half inches in length. In the centre of each of them, as in those passed per urethram, can be seen the straw which served for the nucleus; like the latter, also, they are phosphatic in composition. No accident occurred during the operation, and no particular difficulty was experienced, save in the loosening of the encysted stones. The transversus perinæi artery required to be closed by torsion. The bladder was washed out with warm water, the wound loosely filled with lint saturated with carbolized oil, and the patient put to bed. He rallied well from the operation, and two hours afterward was entirely free from pain—in his own words, "had gotten out of hell into heaven," so relieved was he from the pain which he had suffered for months. On the following morning his temperature was 100°, and his pulse 90; on the third day his temperature was 99¼°, and his pulse 80. On this day the urine began to flow partially through the urethra. On the fifth day his bowels, hitherto confined by opium, were moved by a dose of castor-oil.

At this time the urine was passing almost entirely by the urethra. On the sixth day epididymitis of the left testicle was lighted up, and a day or two later the right testicle became swollen and tender, though not so much as the left. For a few days they were kept supported and enveloped in large hot flaxseed poultices; afterward extract of belladonna, rendered fluid by the addition of glycerine, was applied thickly on sheet lint, and the whole closely wrapped up in oiled silk, and a bandage applied very tightly over all. In a short time the pain and tenderness disappeared. On June 24th, just three weeks from date of operation, he was able to walk around the hospital. At this time he was entirely free from pain, had no difficulty in retaining his urine as long as he wished, and no trouble whatever in voiding it; very little urine flowed through the wound after the fifth, and none at all after the seventh day.

Fort Clark, Texas, June 17, 1881.

# Reports of Hospitals.

## NEW YORK HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

SERVICE OF DR. WILLIAM H. DRAPER.

### CATALEPSY FROM THE USE OF ABSINTHE.

A stout, red-faced Frenchman, addicted to the use of absinthe, was admitted to the hospital, suffering from catalepsy. Any position the limbs might be made to assume they would retain, independent of will-power. Dr. Draper mentioned the case to illustrate the fact that there was hardly any organic nervous disease which could be simulated by a functional derangement. Every disturbance of motion or sensation may be produced by alcoholism, a fact of importance from a prognostic point of view. The patient recovered in a very short space of time.

### INTERMITTENT FEVER OF THE PERNICIOUS FORM.

This patient had been admitted four days previously. He was brought in unconscious, sweating profusely, with a high fever, subsultus, and every evidence of extreme prostration. The only history obtainable was that he had recently arrived from the Orient, having suffered from fever while at sea. The symptoms and periodicity of the disease indicated pernicious intermittent. The administration of medicines by the mouth was found to be impossible. In two or three days, forty grains of quinine were given hypodermically, a quantity equal to two drachms by the stomach. The effect was most happy; the remedy restored consciousness, and caused the patient to cry out for food. Temperature on the fourth day, 93°, pulse 68, respiration 16.

### EXOPHTHALMIC GOITRE TREATED BY QUEBRACHO.

The patient was a woman thirty-seven years of age, of neurotic temperament, and suffering from menstrual derangement. Dr. Draper remarked that organic lesions of the heart were frequently diagnosed in Graves' disease when only functional derangement exists. Where moral causes, grief, disappointment, shock, are at the root of the evil, time was the great restorer. Exophthalmic goitre dependent upon anæmia, chlorosis, menstrual trouble, dyspepsia, or plycosuria, demanded treatment directed to the conditions with which it was associated. This patient was put upon iron in the form of a carbonate, digitalis, and the alkalies. Rest was imperative. Patients of this class were liable to congestion, epistaxis, and œdema of the lungs, under an exaggeration of the original neurosis. This woman had an attack of pulmonary œdema which was associated with exaggerated resonance, and an entire absence of moist râles. She was relieved by the use of quebracho, morphine, nitrite of amyl, and local remedies. Two weeks later the patient had so far improved, under the use of iron and cardiac stimulants, that she was able to walk about the wards. Dr. Draper has employed the iodide of potassium under similar circumstances, with gratifying results in a few cases.

### NERVOUS DYSPNŒA IN A CASE OF SMALL GRANULAR KIDNEY.

On examination of this patient's lungs, breathing was found to be excellent, air entered without obstruction; there was no fluid, and moist râles indicative of œdema were absent; breathing was dry, and there was apparently no congestion whatever. Notwithstanding this, the man suffered extremely from dyspnœa, especially at night. This form of dyspnœa was rather more apparent than real. It was not associated with any obstruction of the air-passages, but depended upon some nervous derangement. It existed in connection with chronic renal disease. This patient's urine was copious, light-colored, of low specific gravity, and contained as a rule about three per cent. of albumen, but occasionally only a trace. He had no œdema.

It is in this form of renal disease, the small granular kidney, that this dyspnœa develops itself. It may be the result of disease of the respiratory centres, or simply a disordered sensation. In the former instance, it occurs in that anæmic condition which is sooner or later the result of chronic renal trouble. In this case it was merely a disordered sensation, no evidences of defective circulation being noticeable. Digitalis and diffusible stimulants would have been of no use to this patient, affording him only a respite of a few minutes. This sensory disorder demands opium. Morphine administered hypodermically affords the most prompt relief. Two minims should be injected at the beginning, and if this quantity fail to relieve, it may be increased to four, five, or six minims.

### RHEUMATISM WITH MANIA A POTÛ.

The patient, a pretty hard drinker, came in with well-marked rheumatism and a high temperature. He was put upon a drug which was said to have a remarkable power in controlling rheumatic fever, but was unsuccessful in this case. After four days he was put upon salicylic acid. The temperature fell from 102° to 98° the following day, in the afternoon of which he began to be delirious. This delirium was not the result of a metastasis of the rheumatism to the meninges, which Dr. Draper believes always occurs in connection with hyperpyrexia; the patient's temperature had not been higher than 101° since he had the delirium. Though the fever was not high, the prostration was excessive and subsultus well-marked. To overcome the insomnia by means of opium is no longer held to be an important element in the treatment of mania a potû, nor is it now regarded dangerous to withdraw stimulants. Food should be given, and if patients will take it they may be considered safe, even if they do nc

sleep. In the severer forms, the means of procuring sleep are the bromide of potassium and chloral. As a rule, stimulants should not be given.

SUBACUTE PLEURISY—CARDIAC DISPLACEMENT.

The patient, a man thirty-eight years of age, was admitted to the hospital in the beginning of August, suffering from shortness of breath, cough, and palpitation of the heart. Six months prior to his admission he had had pleurisy for six weeks. On the day of admission his temperature was 101.2°. August 3d, physical examination showed loss of expansion of the chest on the left side, with bulging of the intercostal spaces. Palpation revealed a lack of expansion on the left side, together with a loss of vocal fremitus, and the fact that the heart-apex beat half an inch below the right nipple. On percussion, flatness was obtained all over the left chest; the base of the heart was not displaced. Auscultation showed a complete absence of vesicular murmur on the left side, and increased breathing on the right. Friction râles were heard on the right side, with cog-wheel respiration at the apex. Vocal resonance was increased on the right side; on the left there was bronchial resonance almost bordering on pectoriloquy. Shortly after admission the patient was tapped, and nineteen ounces of fluid drawn off; on August 6th, twenty-four ounces; then about thirty ounces each day for three days in succession. On the 9th of August, after aspiration, vesicular murmur was heard in the left chest and vocal fremitus could be appreciated. The apex of the heart beat an inch and a half to the right of the left nipple. August 12th, apocynum cannabinum was administered. August 24th, thirty-four ounces of *clear serum* were drawn off. September 9th, the chest again contained fluid. September 20th, the fluid was still clear. Iodide of potassium administered daily. November 2d, the cavity of the left pleura was again full of fluid. Infusion of digitalis was then given, and the quantity of urine on November 5th was sixty-four ounces, and on November 7th, sixty ounces. November 8th, the heart was still displaced to the right, the apex beating about an inch and a quarter inside of the right nipple, in the fourth intercostal space. November 15th, on physical examination, slight vocal fremitus was obtained on the left side, and breathing for some distance below the clavicle on the same side. The level of flatness was depressed, but the heart was still displaced to the right side. The patient was passing about sixty ounces of urine a day. Tapping had been abandoned, and he was put upon digitalis, iodide of potassium, and good diet. His temperature had been moderate since he entered. This case was interesting, because, in spite of repeated tappings, the fluid in the chest had remained serous and clear. [The subsequent history indicated favorable progress.]

GASTRIC ULCER.

The patient was a waitress. Rectal alimentation was resorted to, but failed. When this happens, milk, concentrated broths, and but very little starchy matters are to be given by the stomach. Starch is to be mixed with the milk, in order to prevent the gastric irritation resulting from large flakes of coagulated caseine. The use of bitter waters each morning, to relieve the catarrhal condition of the stomach and to wash out the mucus, is recommended.

SECONDARY SYPHILIS WITH EARLY NERVOUS MANIFESTATIONS.

The patient, a young man twenty-three years of age, denied the existence of any venereal taint, but was convicted of the same by a cicatrix on the penis and a papular eruption on the legs. The case was interesting on account of the occurrence of nervous symptoms early in the disease. Two years and a half prior to his admission the patient began to suffer from attacks of the petit mal, coming on at first once a week, and during which he lost consciousness and fell. These seizures generally lasted about half a minute, and were not accompanied by biting of the tongue or other injury, or by voiding of the urine. Later the attacks became less frequent, occurring about once in three months. These early nervous manifestations are to be distinguished from those connected with the tertiary and quaternary periods. Now and then these attacks of petit-mal, even of convulsions, followed by temporary aphasia or by loss of power, and a variety of other nervous phenomena, are seen in secondary syphilis. These early nervous signs of constitutional syphilis are transient, and depend upon a local hyperæmia, probably upon just such lesions as occur in the skin during the early stages of the disease.

## HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

### CLINICAL LECTURE,

### ON CASES OF HYDROCELE, PALMAR ABSCESS, CLUB-FOOT, AND CONTRACTED KNEE.

BY JOHN ASHHURST, JR., M.D.,

PROFESSOR OF CLINICAL SURGERY.

CURE OF HYDROCELE.

GENTLEMEN: The first case that I have to show you to-day, although no novelty in the clinical amphitheatre, is one, at least, that is always of interest.

The patient tells us that, eight or nine months ago, he noticed, on the left side of the scrotum, a swelling, small at first, but gradually increasing in bulk, until now, by its size and weight, it has become a source of great annoyance. Upon examination, I find quite a large tumor; the skin over it thin, and almost transparent, with some, though not well-marked, enlargement of the superficial veins. The tumor is itself pyriform in shape; in consistency, quite soft and almost fluctuating. I notice, also, that its weight is much less than a mere view of its bulk would lead us to suppose. From what we have already ascertained as to the history of the slow growth of the swelling, as to the symptoms from which the patient suffers, and as to the feel and specific gravity of the tumor, as revealed by palpation, we can at once, without going through with the usual test of transmitted light, proceed with the inference that we have here to deal with a hydrocele, or with hydrocele fluid.

There are two operations to which we can resort in the treatment of hydrocele, namely: the palliative, and the radical. The palliative treatment, which I will employ in the present instance, will, in all probability, be followed by a gradual return of the effusion, until the tumor may equal, or exceed, its present size. By the time that the fluid again accumulates in sufficient quantity to be withdrawn, the patient will, no doubt, be prepared to submit to the radical operation, to be hereafter described.

In proceeding to operate after the palliative

method there are two dangers, both of which one must be careful to avoid, namely: injury done to the superficial veins, but, more important still, to the testicle itself, which in this case, as is usual, is situated at the back of the tumor. Seating our patient on the edge of a chair, anæsthetization being unnecessary, we at once, with a direct thrust, plunge a small trocar and canula into the tumor (avoiding the dangers already alluded to), with sufficient force to pass through all the intermediate tissues at once. When the point is felt to be free within the tunica vaginalis, let the end of the instrument fall, and withdraw the trocar. You will observe that, on the withdrawal of the trocar, a clear, amber-colored fluid, characteristic of hydrocele, flows freely into the basin held by an assistant. When all the fluid possible has been evacuated, the canula may be removed, the scrotum being first pinched up around it, in order to prevent the escape of fluid into the tissues. This is done because, if the precaution is neglected, abscesses may thus be formed. Nevertheless, it is very unusual for such accidents to happen; in point of fact, one method of treatment employed, in cases of hydrocele, is to allow the fluid to drain into the scrotum, and there be absorbed. With the application of a small slip of adhesive plaster over the wound, the operation is concluded, and the patient can resume his usual occupation, without either inconvenience or danger.

There is, however, another variety of this affection, the encysted hydrocele or spermatocele, in which a cyst is developed in connection with some part of the testicle itself. A similar method of operative interference is here resorted to (the fluid withdrawn being sometimes milky white, and with spermatozoa present in it), but it must be held in mind that it is not borne so well as in the ordinary form of hydrocele, and greater care is necessary in the after-treatment, lest serious inflammatory action be set up within the cyst.

The radical treatment of which we have already spoken, and to which this present operation is preliminary, consists in the withdrawal of the contents of the sac, and the injection of some fluid, preferably the tincture of iodine, into the cyst-cavity. I say "preferably the tincture of iodine," for, although many other injections are used, and that, too, with greater or less success, I have found in my experience that, although not invariably followed by a permanent cure, iodine, of all things, can be the most relied on, when used as advocated by the late Professor Syme, of Edinburgh, that is by injecting the undiluted tincture and allowing it to remain. Another mode of treatment sometimes resorted to is the introduction of a seton, which has, however, the disadvantage that it sometimes sets up suppurative, instead of the desired adhesive inflammation.

### HOW AND WHEN TO OPEN AN ABSCESS.

The second case that comes before you to-day is one that has just presented itself, and which I will proceed to examine with you. The hand that the patient shows us is inflamed and swollen, and he tells us that for the last six weeks it has been in nearly the same condition. Observe that the whole palmar surface is hardened and indurated, and at one point the skin is dusky, and there is evidence of the presence of pus under it. We have here, in short, a palmar abscess, than which, on account of the inextensibility of the surrounding tissues, few things are more painful. I generally open an abscess of this kind with a sharp, narrow, straight bistoury, which should be introduced with a quick, plunging motion, and then withdrawn toward the operator. Making the incision in this manner, some little pus is seen to escape, and there is slight bleeding only. As to the after-treatment, I would advise the application of some simple poultice, such as has already been used by our patient, and the arm should then be put upon a splint, which, if not absolutely necessary, is at least of advantage in the keeping of the part at rest. It is not usually considered advisable to open an abscess until it becomes what is called "ripe," but we have, I think, exceptions to this rule in palmar and digital abscesses. In them the tension is so extreme, and the danger of the involvement of the neighboring parts so imminent, that both these forms of abscess should at once be opened, otherwise the tendons may become involved and slough, and the bones even being affected, an amputation may be made necessary. The later complication follows oftener the digital than the palmar abscess. It is argued by some that in opening an abscess before it is "ripe," you may open it in one place, while it may subsequently point in another. To wait until the abscess points is in some cases the best rule to adopt, as in the mammary abscess for example; but in the digital and the palmar abscess, an incision, in the majority of cases, is indicated so soon as, or sometimes even before, the presence of pus is detected.

### THE TREATMENT OF CLUB-FOOT.

This child, aged two years, has what is popularly known as club-foot. It is the most usual variety of that affection met with, and is technically called pes varus. There is also present in some degree pes equinus. The patient has been allowed to walk on the side of the foot for a sufficient length of time to cause the development of a callosity, or corn, in that situation. The best results from operative interference in cases of this kind are usually met with in those instances in which this interference has early been made. But in the present case it is even now not too late to prevent by surgical treatment subsequent changes, in which the bone structure may become involved, and a future more severe operation be made necessary. The best treatment is here unfortunately inadmissible. Where, either in private practice or the hospital ward, you can have your patient kept constantly under careful supervision, you may divide, subcutaneously, first the tendons of the anterior tibial and posterior tibial muscles, and subsequently the tendo achillis, employing gradual extension the while by means of the modified Scarpa's shoe. But if, as here, you will have to rely on parents or inefficient nurses for the carrying out of your directions, since you cannot do the best, you must do the next best thing, which is to at once divide all three tendons, straighten the limb, and fix it immovably in a plaster-of-Paris bandage. When the slight inflammation which attends such a trivial operation as tenotomy subsides, remove the bandage and apply an ordinary frame shoe. The first operation spoken of, followed by the application of the varus shoe, is by far the best, but the supervision of the case must be your own, or else the result in great probability will not be successful. The operation, as already described, consists in either case of the subcutaneous division of the tendo achillis and of the tendons of the anterior tibial and posterior tibial muscles, and sometimes, as in the case before us, of the plantar fascia. Whereas, in cutting the tendo achillis and the tendon of the anterior tibial muscle the operation consists merely in

the subcutaneous division of these tendons by means of the sharp-pointed tenotome, in the section of that of the posterior tibial muscle additional caution is necessary, for the wounding of the posterior tibial artery would be an awkward accident, and would perhaps prevent primary union, which, in an operation of this kind, is always sought for. For the avoidance of this risk it is advisable to make the preliminary puncture with a sharp-pointed knife, and in the deeper part of the operation to employ a blunt-pointed tenotome.

Observe that in withdrawing the knife after each of the incisions above described, the superficial wound is immediately closed by the finger, and there is applied as quickly as may be a small piece of lint wet with a little compound tincture of benzoin, and held in place with a strip of adhesive plaster.

These precautions are intended to prevent the entrance of air through the superficial puncture. Having, then, divided all the tissues necessary, we find that the foot, which is pretty well everted, can by force be made almost straight. The parts are now to be cleansed if there has been any bleeding, fresh pieces of dressing applied if the first used have become displaced, and the foot then fixed in a normal position by the immovable bandage. Let me repeat that I do this because, as the patient will not remain under our constant supervision, it is the best that can be done in this particular instance.

In the application of the plaster dressing I adjust first about the leg, as you see, a roller of flannel, on account of its softness and elasticity. Then a narrow plaster-bandage is carefully and evenly applied, with a view to the equal distribution of pressure over the whole leg, and the avoidance of anything like circular compression; for a certain amount of swelling follows even such a trivial operation as tenotomy. With the application of a little dry plaster to give it a finish, the dressing is completed, and the parts are seen to be immovably fixed in the position which they would normally occupy. In two or three weeks, the wounds resulting from the operation having in that time long since healed, the bandage may be removed, and the use of the shoe instituted. This shoe may be the ordinary frame shoe, with an iron on each side and a single hinge for the ankle, by which walking will be permitted, while a return of the deformity will be prevented.

CONTRACTED KNEE.

The fourth and last case that I shall have an opportunity of exhibiting to-day is that of this little girl, whose history runs as follows: As a result of some slight injury, her knee-joint began to swell, and the physician who had her in charge before she came into the hospital said, according to the child's parents, that there was a fracture. Upon a careful examination, however, I fail to detect any of the signs of such an injury. The small opening which is seen on the outer surface of the affected knee is the result of suppuration, and is kept open and prevented from healing by the constant action of the hamstring tendons. The slight swelling which is present about the knee-joint is probably due to an early stage of synovitis. The operation that I intend to perform is the cutting of both hamstring tendons, with the twofold object in view of straightening the somewhat contracted knee, and, by putting the limb at rest, of favoring the healing of the sinus. To cut the hamstring tendons, it is best to introduce the knife in the median line, with its point directed toward the edge of the limb, thus avoiding the risk of wounding the popliteal artery. It is usually advisable to cut the tendon of the most contracted side first, and to then decide on whether the section of the other will be necessary. The tenotomy wounds having been treated in the usual manner, we will place a little lint spread with zinc ointment over the sinus, and then apply a flannel roller around the leg, with a view of protecting all bony prominences. Now I apply the plaster roller far up and far down the leg, keeping the pressure equalized, and strengthening the knee and rendering it immovable by the addition of a few figure of eight turns around it. Dry plaster is then applied as before. There is but little doubt that when in the course of five or six weeks the bandage is removed, the leg will be found to be straight and the sinus completely healed.

## Progress of Medical Science.

PHARYNGEAL HERPES.—In the *Pester med.-chir. Presse*, No. 19, 1880, Dr. I. Herzog calls attention to this rather rare affection. He states that, pathologically, this form of eruption resembles ordinary cutaneous herpes. Owing to the location of the disease, however, the vesicles, after bursting, form no crust, since the products of coagulation have no chance to dry up, but are washed away with the pharyngeal secretions. This "herpes pharyngis" is said to begin with violent fever, accompanied by severe headache. Gastric derangements are also observed. The eruption as a rule appears on one side only. After subsidence of the initial constitutional symptoms, the eruption replaces the ordinary throat catarrh. This occurs on the second or third day. The faucial mucous membrane becomes considerably swollen. At first perfectly clear vesicles appear; soon, however, their contents assume a yellowish tinge. They may be present in groups, or else occur widely scattered. An irregularly serrated, dark red border surrounds them. When the eruption is widespread, the fauces appear as if covered with dewdrops. After twenty-four or thirty hours, distinct little ulcers are seen in place of the vesicles. The floor of these ulcers has an opalescent look. Relapses may occur, and then the disease may run a longer course than the usual one of eight or ten days. In rare instances, deep ulceration is observed, and such cases are apt to create erroneous impressions and lead to mistakes in diagnosis. Sometimes, in place of the vesicles, variously shaped plaques, of small size and yellowish color, may develop. They appear as loosely adherent false membranes, which suffer rapid and spontaneous desquamation. Herzog thinks that this affection should be regarded as a trigeminal herpes zoster, in consequence of irritation of the spheno-palatine ganglion.—*Jahrbuch für Kinderheilkunde*, December 23, 1880.

HISTOLOGY OF THE LUNG.—Professor Kölliker had occasion to examine the lungs of a criminal one-half hour after his execution. As the result of careful microscopical investigation, he states that the human alveolar epithelium consists of a continuous layer of basement-cells of two different kinds: 1st, small nucleated, flat, polygonal bodies, with protoplasm confined exclusively to the meshes between the capillaries; and 2d, large multiform, very thin plates

without nuclei, which lie immediately upon the blood-vessels. The same was found by Elenz and Eberth in the lungs of mammalia in 1864. The bronchioles, from 0.5–0.4 mm. in diameter downward, are of two kinds: tubes, lined with ciliated epithelium; and bronchioles, lined either with cylindrical or small basement-epithelium, or large, polygonal basement-cells. Both carry alveoli, which have the same epithelium as those of the infundibula, which Kölliker calls respiratory epithelium. Where the ciliated epithelium has been transformed into a small basement-epithelium, and this again into respiratory epithelium, we have a structure known as the alveolar passage (*Alveolengaenge*), several of which unite to form the bronchioles. This, and the relation of the pulmonary artery to the mucous membrane of the smallest bronchi, demonstrates that those portions of the lung which play the most important rôle in endosmosis and exosmosis must be looked for much nearer the bronchi than has been hitherto supposed. —*Schmidt's Jahrbücher*, January 27, 1881.

The Physiological Action of Alcohol.—Experiments made by Dr. Riess with absolute alcohol, diluted to forty per cent., show a considerable decrease of the most important constituents of the urine, and an increase of the weight of the body amounting to eight hundred and eighty grammes. The temperature and pulse remained normal. Considering that the change of diet to one richer in nitrogen ought to have produced an increase in the amount of nitrogen excreted, and that diuresis was increased, and, consequently, a tendency to a more abundant excretion of urea, the result obtained demonstrates anew that alcohol is to be regarded as a food, and that its favorable influence upon the condition of the organism is attributable not alone to its stimulating, but also to its "nourishing" properties.—*Schmidt's Jahrbücher*, January 27, 1881.

Is the Uterine Mucous Membrane Desquamated during Menstruation?—At a meeting of the Société de Biologie, M. de Sinéty reported having had opportunity to make a number of autopsies on women who died during menstruation, and that he found the uterine mucous membrane intact. To further prove his assertion, he examined, with great care, in a very large number of cases, the fluids expelled during menstruation, but was not able to detect the slightest trace of corpuscular elements of the mucous membrane. He therefore concludes that desquamation of the uterine mucous membrane, a process assumed by many to be a physiological one, does not occur during menstruation.—*Gazette des Hôpitaux*, March 8, 1881.

Local Anæsthesia of the Larynx.—Professor Schrötter, of Vienna, practises local anæsthesia of the larynx by the following method. On the evening preceding the day fixed for the operation, the interior of the larynx is thoroughly painted over with chloroform twelve times in succession, in order to produce hyperæmia of the mucous membrane, which favors absorption of the narcotic to be subsequently used. The latter is applied with a brush an hour later, in the shape of a concentrated solution of sulphate of morphine. This is also used twelve successive times, the patient being instructed to gargle immediately afterward with a solution of tannin. During the night the patient must be kept under observation, in order that signs of morphine-poisoning which might arise, may be promptly treated. As a rule, the larynx will be found in the morning to be completely anæsthetized so that the operation can immediately be performed. If there is still some susceptibility remaining, this can be easily and safely removed by repeating the painting with morphia, which need occupy but a few minutes. The author acknowledges that his method is in a degree disagreeable to the patient, especially the application of the chloroform. But it is nevertheless infinitely preferable to tracheotomy, which would otherwise be necessary. It is, however, rarely resorted to, since there are few larynges which will not yield their susceptibility to the repeated use of the sound.—*Allgem. Wiener medizin. Zeitung*, March, 15, 1881.

Fatty Embolism.—Dr. Lepp, of Leyden, contends that the presence of fat-emboli in living warm-blooded animals has not been proven. Embolism can only occur when the blood-pressure is not powerful enough to overcome the resistance which the fat-globule encounters in the capillaries. This resistance is undoubtedly due to the cohesive power of the fat, which diminishes rapidly at a high temperature. Therefore, we cannot apply the fact that fat-emboli have been found in living cold-blooded animals to warm-blooded ones, whose blood-pressure is much greater and whose temperature is higher, both conditions being very unfavorable to the existence of fat-globules. Their intravascular discovery post-mortem is no proof of their presence in the vessels during life, since it is very likely that it is only during the death-struggle that the blood-pressure becomes so much diminished as to allow the entrance of fat-globules into the vessels.—*Centralbl. für Chir.*, March 5, 1881.

Therapeutic Use of the Bromhydrate of Conia.—The following are the principal points extracted from an extended study on the medicinal action of hemlock by Dr. Tuloup (*Bulletin de Thérapeutique*). The organs of special sense, the digestive functions, and the temperature are but slightly affected by conia. Death ensues in consequence of asphyxia. Bromhydrate of conia gives rise to the same signs of intoxication as the ordinary alkaloid. It appears to possess, however, a greater energy of action. Respiration is the function which is chiefly influenced by it. At first accelerated breathing is produced, but this soon makes place for a decided retardation, and asphyxia may be finally developed, owing to this slowing. The cause of the asphyxia is not to be looked for in a paralysis of the terminal branches of the pneumogastrics, but rather in a direct action on the respiratory centre. Several distinct phases, each with characteristic symptoms, are observable in connection with poisoning by the bromhydrate.

The drug may be administered under any form. In order to produce an appreciable effect on an adult, one grain and a half may be exhibited in two doses during the twenty-four hours. The idiosyncrasy of the patient will then have to be our guide as to the amount of necessary increase in the dose. Four grains and a half a day should not be exceeded. It may be employed with advantage in all spasmodic affections, but particularly those of the respiratory organs. Pertussis, asthma, various forms of dyspnœa, emphysema, laryngitis stridulus, spasm of the glottis, and spasmodic dysphagia are symptoms or diseases in which it should be given. But epilepsy, tetanus, eclampsia, hysteria, infantile convulsions are equally amenable to treatment by this means. Neuralgia, especially when associated with spasms, is likewise controlled by the bromhydrate of conia.—*Moniteur de la Policlinique*, March 13, 1881.

New York, July 16, 1881.

## THE COMING INTERNATIONAL MEDICAL CONGRESS.

THE meeting of the International Medical Congress, to be held in London from August 2d to August 9th, promises to be of more than ordinary interest. Arrangements have been made by the committee in charge, not only to insure a successful working of the usually extensive and varied programme on such occasions, but efforts have been made to give the meeting more of an international character than has been the case heretofore. Special pains have been taken to secure the attendance of representative medical men from all parts of the world, and the subjects to be discussed have been selected with a view of bringing out the best available talent. A large number of foreigners have already signified their intention to be present, and the prospect now is that the membership will greatly exceed that of any former meeting. The amount of material to be discussed is immense, and at first sight would appear to be more than can be satisfactorily disposed of during the few days of the session. Still, the system of arrangement is carried out with such precision, that there is a reasonable hope that the ground mapped out will be duly and efficiently worked over.

In the present congress the English, French, and German languages are to be spoken. Heretofore, but one, or, at most, two languages were declared official. In making this laudable departure from what has been an accepted rule, our English cousins have undoubtedly expanded the resources of the congress, and have given it a truly international character. Each member can present his paper in his own language, while in the volume of Transactions an abstract of his remarks will be published in the three official languages. It is to be regretted that the same course cannot be taken with the discussions. The latter, as we understand, are to be printed in English only. While such a plan necessarily avoids a confusion of tongues in open meeting, it has its drawbacks in that many of the members, although able to understand the papers in a foreign language, will not be able to discuss them in any but their own tongue. The majority of the English members will have the advantage in this respect, in that they will be able to understand German and French authors, and, of course, use their own language in the discussions. But this difficulty may be more apparent than real. It would seem practicable while the discussions are only to be published in English, that each foreigner making remarks might be allowed to use his own language. But we have no doubt that suitable arrangements will be made to meet the needs of all concerned.

The main work will be done in the sixteen sections. These will meet in the morning from 10 A.M. to 1 P.M., while the general sessions, at which the formal addresses are to be delivered, will be held daily from 4 to 5.30 P.M. According to previous custom, the abstracts of the papers to be read before the different sections will be published before the meeting, giving ample opportunities for preparation on the part of such as desire to take part in the discussions. This plan will not only save the time of the meetings, but will be calculated to bring out the best thoughts of the participants. Each section has a series of eight or ten subjects for discussion, and their arrangement is as systematic as could be desired. Among the topics are—In Anatomy and Physiology: Improved Methods of Instruction in Anatomy, The Functions of the Cortex Cerebri, The Intimate Structure of Cells and Nuclei. In Pathology: The Relations of Minute Organisms to Disease, Tubercle, and the Origin of Cancer and Sarcoma. In Medicine: The Localization of Disease in the Brain and Spinal Cord, and Forms of Renal Disease, with a subsection on Laryngology. In Surgery: Recent Advances in the Surgical Treatment of Intra-peritoneal Tumors, Recent Advances in the Method of Extracting Stone from the Bladder of the Male, Union by First Intention, The Treatment of Aneurism by Esmarch's Bandage, and Syphilis. In Obstetrics: Antiseptics in Midwifery, the discussion being opened by Professor Spiegelberg; Total Extirpation of the Uterus, by Professor Freund; Oöphorectomy, by Dr. Battey. In Diseases of Children: Syphilis as a Cause of Rickets, Spinal Paralysis, Diphtheria, and Chorea in its Relations to Rheumatism. In Mental Diseases there is an elaborate programme, embracing Anatomical, Physiological, Pathological, and Chemical Aspects of these diseases.

A museum for the exhibition of objects of special interest in pathology, clinical medicine, and clinical surgery, will be one of the distinctive features of the meeting. The exhibition is promised of groups of patients with the following rare diseases: Addison's Disease, Coincidence of Gout and Rheumatic Ar-

thritis, Charcot's Joint Disease, Myxœdema, Syphilitic Bone Disease in Children, Mollities Ossium, Primary Muscular Atrophy, Rupture of Large Nerve-trunks, Morphœa, Keloid of Alibert, True Leprosy, Lupus Erythematosus, and Xanthelasma.

Another feature of the museum will be the classified collection of drawings, also a collection of vesical calculi of unusual character, and especially of such as have been removed by unusual or new methods, and of biliary calculi of large size, which have discharged, or have been removed by operation.

The social elements of the meeting are so managed, and are few enough in number, not to interfere with the strictly scientific business. There will be a soirée at the College of Surgeons and one at the South Kensington Museum. The committee also propose an out-door fête at the Botanical Gardens. Tickets of membership—one guinea each—procure admission to these entertainments; but all expenses for luncheon and incidental expenses are met by individual members.

Notwithstanding, by the disposal of tickets and the collection of subscriptions, nearly thirty-five thousand dollars have been raised for the expenses of the Congress, it is claimed by the managers that a still larger sum is needed to defray the necessary expenses. It is concluded that the cost of publication of the "Transactions" alone will vary from twenty-five to thirty thousand dollars, according as there may be one or two volumes of the same. This is such an extravagant estimate, that there is reason to suppose there must be some error in the statement.

Every facility is offered for the registration of members. The formalities of registration are reduced to the minimum of ordinary medical qualification and the payment of the membership fee. The latter is curiously enough exacted of all members, whether they have subscribed or not.

As we have already stated, the promises for a large and profitable meeting are good. The representatives from this country will be, as to quantity and quality of membership, much better than is usual on such occasions, and it is fair to hope that the work which they will perform will reflect credit on American medicine. But the true character of this and other work in the Congress can be duly estimated when the full report of the Congress is made.

---

### THE PRESIDENT'S WOUND.

NATURALLY there has been a great deal of discussion in the newspapers and elsewhere concerning the probable course of the bullet in the case of President Garfield. Despite the extensive interviewing of surgeons by reporters, no conclusion has yet been arrived at. The case presents some unusual difficulties in diagnosis, which should be taken into account by such medical men as have so freely ventilated their opinions before the public. It is a matter for great congratulation that the weight of evidence at present is in favor of the escape from injury of the liver, as well as other vital organs in the neighborhood. In other words, every one is satisfied to learn that the original opinion regarding the nature of the wound is likely to be a mistaken one. Nothing better than this could possibly happen under the circumstances. But it is not just to the gentlemen who have been in attendance upon the President, and who made the diagnosis of a mortal wound, to hold them to account for the error which, in all probability, they committed. It is easy enough for any surgeon of ordinary intelligence to assume in the light of recent events that no vital parts have been struck, and still more so is it for gentlemen who know nothing of the case, except from hearsay, to declare how easy a proper diagnosis might have been made. On general principles it is always safe and proper to give due preference to the opinions of the surgeons in actual attendance upon the case, and to exercise toward them a becoming charity for mistakes supposed to have been committed. There are always circumstances to be taken into account of which the mere outside theorizer has no possible knowledge. Hence, his opinions are usually gratuitous, and his advice generally worthless.

The original idea of the wound, as entertained by the gentlemen who first saw this notable case, was a natural and reasonable one under the circumstances. A great deal regarding the actual course of the missile had to be left to inference. If thorough and repeated probing was the only thing necessary to clear up the doubts of the critics, we are glad to be still in doubt. In reality, too much credit cannot be given to the gentlemen in attendance, for their forbearance in this matter of probing. They followed a strict surgical rule in this respect, and wisely rested their opinion upon conjecture rather than upon demonstrated fact.

So far as we can learn, there were but two examinations made of the wound to determine the course of the ball: one by Dr. D. W. Bliss, who cautiously introduced a probe for a distance of three inches into the wound, in a direction from behind forward and slightly downward, and Surgeon-General Wales, of the navy, who followed the same track with his little finger to the entire length of the latter. Both gentlemen were of the opinion, from such examinations, that the liver had been wounded, and Surgeon Wales believed he felt the track in the organ itself. This should be admitted as very direct testimony. It was all that was necessary to obtain under the circumstances. To have gone farther might have given an altogether different termination to the case. The sin, if any, was one of omission, and is always pardonable when any of the large cavities of the body are supposed to be entered by a ball. In the light

of subsequent developments it is quite probable that the missile has been deflected from the course it was originally supposed to have taken; but it does not appear, from anything that has been said by the army of interviewed medical men, that the precise direction of the missile could have been determined with any more certainty or by any other means, without placing the life of the patient in jeopardy. Under other circumstances the surgeons in charge would have been very justly condemned for their officiousness. As it is, the country have the best of reasons for applauding their forbearance.

It does not appear, from anything that has been learned of the history of the case, that any of the symptoms could have been ameliorated by the finding of the ball or its extraction. Certainly the patient could not have done better. The general management of the case, even under the grave suspicions of liver injury, could not have been more judicious, or the general treatment more skilful. The error, if such we may call it, has been on the safe side from the beginning to the present.

The ball itself, although of large size, was not of a character to cause any extraordinary amount of irritation—at least, not so much so as the portions of clothing which may possibly have accompanied it.

But these are, of course, matters the importance of which can be estimated only in the light of coming events. It is sufficient for us to know at present that the wound discharges freely, and that every symptom in the case is favorable. There is perhaps nothing better to wish for in the light of the present progress of the case, than that the President's condition will soon warrant even the discontinuance of the morphine. But this matter can of course be safely left to the judgment of his medical advisers.

The precise direction of the ball is a matter for much interesting study. The data are not numerous, and are mostly of a negative character. All that can be done at present is to make the most of them and interpret their significance as best we may.

Of course no one can say as yet where the missile really is, and unless more pronounced symptoms are developed there is a probability that no one ever will. At least, let us hope that the ball, wherever it may be, will quietly become encysted, and that the illustrious patient may finally make what now promises to be a satisfactory recovery.

In the present number an attempt has been made by Professor Weisse to explain a possible course of the bullet—deflected downward from the eleventh rib, wounding the ilio-hypogastric and ilio-inguinal nerves, and finally impinging upon the sacral plexus. The theory is an ingenious and plausible one, and helps to elucidate some of the problems in the case. At all events it is an interesting study of the surgical anatomy of that region.

### AN AMERICAN RED CROSS SOCIETY.

THERE is a likelihood that the league of the Red Cross will ere long have a branch organization in this country. Through the efforts of Miss Barton, an American lady, whose services during the late war of the rebellion are well known and duly appreciated, the matter has been brought to the attention of Secretary Blaine, and will, at the proper time, be presented to Congress for suitable action. Since the Geneva Conference, held in 1863, the Society of the Red Cross has extended its auxiliaries into every country of Europe, and has indicated its utility in every war that has occurred during that period. It was originally organized for the purpose of establishing soldiers' relief societies in various countries, under a common badge, for protecting, in time of war, hospitals, ambulances, hospital stores, and supplies for the wounded, and for maintaining a strict neutrality on the part of belligerent powers toward all members of the society while in service. This treaty, subsequently amended, has been endorsed by twenty-seven governments, and is consequently of a thoroughly international character. Indeed, the purposes and designs of this organization are past the necessity for advocacy on the part of any humanitarian, and are beyond the chances of question as regards its extended utility and beneficent results. If there had been any doubts on this score, they were especially dispelled by the labors of the Red Cross Society during the Franco-Prussian war of 1870–71. As soon as the war was declared the Berlin Red Cross organization, numbering nearly two thousand members, offered its services, and distributed squads all along the frontier. Every facility was offered for transportation, free communication of supplies was established, and prompt and efficient aid made available at all times. The operations were carried on with the most perfect system, and on a sufficiently extensive scale to insure a most satisfactory working of details and a corresponding benefit to the sick and wounded.

It is fair to suppose that there never has been nor never will be any objection to the establishment of a Red Cross Society in this country. The only probable reason why no direct action in its establishment has been undertaken heretofore in this country is, that the real necessity for the same in possible and frequent wars has not been apparent. But Miss Barton, with a view of adapting the purposes of the organization to the real need of the nation, has proposed that, in addition to the care of the sick and wounded on the battle-field, its benefits shall be extended toward such as suffer from pestilence, famine, or other wide-spread calamities. Concerning this point, Miss Barton, in her memorial, makes the following practical suggestions:

"It may be further a part of the work of these societies in America to afford ready succor and as-

sistance to sufferers in time of national or widespread calamities, such as plagues, cholera, yellow fever, and the like, devastating fires and floods. The readiness of societies like those of the Red Cross, to extend help at the instant of need, renders the aid far more valuable and efficient than that gathered together hastily and irresponsibly in the bewilderment and shock which always accompany such calamities. The trained nurses and attendants subject to the relief societies in such cases would accompany the supplies sent and remain in action as long as needed. Organized in every State, the relief societies of the Red Cross would be ready with money, nurses and supplies to go on call to the immediate relief of all who were overwhelmed by any sudden calamity. It is true that the Government is always ready in these times of public need to furnish transportation, and often much more. During the late yellow fever epidemic in the South, and more recently at the time of the floods in Dakota, it ordered rations, clothing and tents to be distributed under the direction of army officers. But in such cases one of the greatest difficulties is that there is no organized method of administering the relief which the Government or benevolent citizens are willing to bestow, or trained and acclimated nurses ready to give intelligent care to the sick; or, if there is organization it is hastily formed in the time of need, and is therefore comparatively inefficient and wasteful. Although the people of the United States may hope to be seldom visited by the calamities of war, yet the misfortune of other nations constantly appeal to their sympathies. And in this country the South is periodically visited by the scourge of yellow fever; the valleys of the Mississippi are subject to destructive inundations; the plains of the West are devastated by drought and insects; and cities and country are swept by consuming fires. In all such cases to gather and dispense the profuse liberality of the people, without waste of time or material, requires the wisdom that comes of experience and permanent organization. To secure such permanent organization the American Association of the Red Cross has been founded."

It is gratifying to learn that proper initiatory steps have already been taken to organize the American Red Cross Society; a constitution has been adopted, officers have been elected, articles of incorporation are being prepared, and other matters are receiving attention with the view of having everything in readiness for the formal and necessary national recognization. There is no reasonable doubt that the latter will be done as soon as opportunities may be offered for legislative action, and when such is accomplished we shall doubtless have a systematized relief association which shall even be more helpful to the sick and suffering during times of peace than similar organizations have ever been to the wounded and dying on the battle field.

### DAILY MEDICAL JOURNALS.

Since the Medical Record, in June, 1880, published the first daily edition of a medical journal, its example has been followed by several of its contemporaries. Our esteemed neighbor, the *Boston Medical and Surgical Journal*, shortly after issued a daily edition containing the proceedings of the Massachusetts State Medical Society; the *Medical Annals*, of Albany, with becoming enterprise, published daily the reports of the meetings of the Medical Society of the State of New York; the *Chicago Medical Gazette* did the same thing for the Illinois State Society, while the *Virginia Medical Monthly* reported in special editions the proceedings of the American Medical Association at Richmond; lastly, the *New York Medical Times* (formerly the *Homœopathic Medical Times*) issued a daily edition during the late meeting of the American Institute of Homœopathy at Coney Island. Verily, daily medical journalism is gradually getting into the fashion, at least on the occasions of notable medical gatherings.

The coming meeting of the International Medical Congress will afford an opportunity for becoming enterprise on the part of our leading English contemporaries.

## Reports of Societies.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, April 27th, 1881.*

Dr. T. E. Satterthwaite, President, in the Chair.

### CEREBRO-SPINAL MENINGITIS.

Dr. F. A. Burrall, on invitation, presented specimens illustrating the lesions of cerebro-spinal meningitis, accompanied with the following history, furnished by Dr. John F. Duffield, Acting House Physician at Presbyterian Hospital:

Susan McArthur, aged nine years, a native of New York, was admitted to the service of Dr. F. A. Burrall, April 13, 1881.

She was brought in an ambulance and was in a semi-comatose condition. She had been living in a miserable tenement-house. Anything like a direct rational history of the child's condition previous to admission could not be obtained. Her hygienic surroundings had been extremely sad in every particular, especially as regards drainage, ventilation, and overcrowding. Her father and mother were intemperate. The child seemed to have been in her usual health up to the time she was taken sick. No other cases of sickness were in the house at the time, although it was subsequently discovered that a child in the same house was taken ill at about the same time, and died four days later, with similar symptoms.

So far as could be ascertained, on the afternoon of April 10th, the child had frontal headache and began to complain of abdominal cramps, which were soon followed by diarrhœa, and what was evidently projectile vomiting. No reliable history of a chill, but

there was almost immediately a rise of temperature. She did not complain particularly of headache, but of a general feeling of soreness. Vomiting and diarrhœa continued at intervals for twenty-four to thirty-six hours, when they ceased. Within a few hours she began to grow dull, and gradually lapsed into a semi-comatose condition.

On admission, the patient was poorly nourished and stunted in growth, and almost completely comatose. With some difficulty she could be aroused enough to protrude her tongue. Anxious expression, cheeks flushed—the left apparently more so than the right. Ptosis of both eyelids; conjunctivæ deeply congested; pupils dilated equal, and responded slowly to light; no appreciable photophobia. Dry, brown tongue, and sordes on the teeth. Well marked opisthotonos. Whole body in a state of flexion. All attempts at bending forward the head are evidently painful, but there are no other tender points, even on rather forcible manipulation. No general hyperæsthesia. Child lies perfectly quiet, with body in above condition, except at stated intervals of from five to fifteen minutes, she begins a series of jactitations (not convulsions): raising the right hand to the head as if in pain, scratching her nose, boring her head into the pillow, and at times tossing herself around until she has made a complete circuit of the bed. She also gives at these times a sharp, moaning cry, which is the only sound she utters. These attacks last from a few seconds to a minute. Passes urine and fæces freely. Physical examination of heart and lungs negative. Temperature, 102½° F.; pulse, 115; no eruption; no vomiting.

*Examination of urine.*—Specific gravity, 1028; acid; one-fourth albumen per volume; no casts; loaded with urates.

*Treatment.*—Sinapisms to nape of neck, after mustard-bath; ℥ iv. Magendie hypodermically, with effect of somewhat shortening the duration of the paroxysms and diminishing their intensity.

April 14th.—Pulse, 74, regular and moderately full; temperature, 101½°. Opisthotonos more marked. Pupils now slightly contracted, equal, and still respond feebly to light. Cannot be aroused, though takes nourishment freely by mouth. No eruption. No general hyperæsthesia. The jactitations continue at about the same intervals and with same intensity. Ordered hot mustard-bath t. i. d., with continuous strong sinapisms to nape of neck, which seemed to quiet the patient somewhat. Hydrarg. chlorid. mite, gr. ⅛, every hour until free fecal movement. Four doses sufficient. Iodid. potass. in five-grain doses every two hours; brom. potass., gr. x., every hour; ʒ j. was given, with slight, if any effect. Milk with brandy, in proportion of half an ounce to four ounces, ad lib. 8 P.M.—Pulse, 132, considerably weaker, but regular; temperature, 102½° F.; respiration shallow, but regular, averaging 28. General condition unchanged. Tongue very dirty, but moist; sordes increasing. Face deeply flushed, and countenance getting dusky. No lung-complications. McMunn's elixir opii, ʒ ss. in divided doses, quieted her somewhat during the night.

April 15th, A.M.—Pulse, 90, non-intermittent; temperature, 101¾° F. Opisthotonos increased. Head bent sharply back to an extreme degree, while the vertebral column is bowed considerably. Left side paralyzed. Internal strabismus, left side; pupils dilated, fixed, and non-responsive to light; conjunctivæ excessively congested. Well-marked abundant petechial eruption on shoulders, arms, thighs, knees, buttocks, and trunk. Dysphagia. Hot baths continued. Bromid. and McMunn given freely during the day, with brandy doubled. Paroxysms now became more violent, and toward evening began to be more convulsive in character.

6 P.M.—Pulse, 168 approximately; very weak, intermittent, and fluttering. Opisthotonos extreme; still no general or local hyperæsthesia. Face very dusky; beginning œdema of lungs. Respirations still regular, number 32; temperature, 105° F.

9 P.M.—Pulse not perceptible. Temperature, 106¼° F. Died after a well-marked convulsion.

*Autopsy*, made seventeen and one-half hours after death.—Body fairly nourished. Rigor mortis quite well marked. Posterior and also lateral surfaces of body marked with livid spots of various sizes; also anterior surfaces of both arms and upper part of both forearms and knees exhibited little clusters of punctate spots, each spot of the size of the head of a small pin. Some spots were seen over the free border of the ribs on the right side. The peritoneum, and all the serous membranes exposed, presented a very deep, almost violet color. The pericardium contained a drachm of clear serum; membrane normal. The heart weighed three ounces and one-half; valves normal, right ventricle of auricle contained white clots; left ventricle contained fluid blood. The left pleural cavity contained some old adhesions at the base of the lung. The left lung weighed four and one-half ounces; hypostatic congestion of the lower lobe; crepitated throughout; diaphragmatic pleurisy. The right lung weighed five and one half ounces, crepitated throughout. The spleen weighed two and one-half ounces. The liver weighod thirty ounces, was congested, and softer than normal. The right kidney weighed two ounces, the left two and one-half ounces, rather soft; cortex looked fatty, no irregularity in markings. The brain weighed two pounds and fourteen ounces; intensely congested, and in meshes of pia mater were collections of purulent material. The blood-vessels, after opening the dura mater of the cord, were found distended with blood, and in the meshes of the pia collections of pus were found.

Dr. Ripley remarked that the scarcity of the exudation and the gravity of the symptoms seemed to be the peculiarity of the case.

Dr. Heineman remarked that cases with marked symptoms occurred, in which at autopsy little or no lesion was found, except congestion of the pia mater. The lesions of cerebro-spinal meningitis are simple congestion, congestion with a little patch or patches of exudation, or, less frequently, a great deal of exudation. To find a large quantity of exudation is rather the exception than the rule; although in some epidemics the cases are characterized by an abundance of inflammatory products, while in other epidemics the lesions are less marked.

The President remarked that in Dr. Burrall's specimen the plastic exudation was limited, while the congestion of the pia mater was very extensive.

Dr. Ripley thought that exudation was almost always present, and that, as a rule, it was considerably abundant. Rodenstein had made autopsies, and found scarcely any lesion, but believed that coagulated material was always present.

Dr. Heineman remarked that there was one exception to Dr. Ripley's statement—namely, that patients might live four or five days with well-marked cerebro-spinal meningitis, and at autopsy only congestion of the meningitis be found.

Dr. Ripley remarked, as a clinical fact, that there is no disease in which the symptoms are so irregular

as in cerebro-spinal meningitis. There are sudden and excessive variations in temperature, and so with the nervous symptoms, the condition of the pupil, etc.

SPECIMENS ILLUSTRATING THE TRAUMATIC ORIGIN OF CANCER.

DR. A. P. GERSTER presented a specimen of cancer of the leg, in which the traumatic origin of the lesion was well established. A woman, aged sixty years, received on the outer margin of the sole of the foot a simple erosion of the skin from stepping on a nail, and the injury terminated in an ulcer, which repeated itself several times, and finally a small elevated ulcer formed that continued to enlarge slowly for thirteen years. It gave her some trouble in walking, but she did not deem it necessary to consult a physician. Whenever she gave herself rest for ten or twelve days, the entire ulcer, about three inches square, became covered with a newly formed epidermis and the discharge ceased; but, as soon as she began to use the foot, the previous symptoms all returned. At first Dr. Gerster did not suspect its serious character, and supposed he had to deal with a granuloma caused by the constant irritation produced by walking. In August, 1877, it was excised, the wound healed by secondary intention, and remained closed for about six weeks. Four months afterward the foot presented a very formidable appearance. Its surface was covered with irregular-shaped tumors, some of them of the normal color of the skin, and others had a dark tint pointing to the melanotic character of the disease, and a number of lymphatic glands in Scarpa's space were enlarged. Dr. Gerster proposed amputation, which he did in May, 1878. After the operation the patient said that for three or four weeks she had had double vision. During the time occupied by the stump in healing, the diplopia increased, exophthalmos took place on the left side, and at the same time small tumors appeared in the skin of the entire body; some of them were large enough to be visible to the naked eye and others were only large enough to be felt as the hand passed over the surface. The pain in the eye became so excruciating that the patient committed suicide with morphine. The nodules had been examined microscopically, and were found to be cancer containing only a very few connective-tissue elements. Besides the integuments, almost every internal organ was involved. Dr Gerster was positive that, when the tumor was first excised, in 1877, none of the internal organs were involved; but at the autopsy deposits were found in the brain, heart, pericardium, anterior surface of the peritoneum, in the liver, kidneys, and lungs.

The second specimen was a foot which he had removed from a man fifty-one years old, who from his childhood had had a small wart over the tip of the outer malleolus. When he was twenty-one years old the wart gave him a great deal of trouble, and a surgeon removed it with the actual cautery. The man said that it was not removed completely, but it gave him no serious trouble until about six months ago, when it began to bleed profusely on the slightest irritation, and enormous deposits of epithelial matter formed upon the top of the tumor. A small portion was removed and examined microscopically, and was found to be epithelial cancer. Amputation was performed ten days ago.

A third case of a similar character occurred in his practice about three years ago. A man, fifty years old, a baker, received, thirty years ago, a severe burn, extending over a large portion of the right lower extremity, on its frontal aspect. An extensive cicatrix remained, which did not give him any trouble until eleven months ago, when he hit his shin against a barrel. A small abrasion remained which did not heal, but began to enlarge, secrete profusely, and finally presented all the external appearances of an epithelial cancer. Amputation was performed, and examination of the growth proved it to be a cancer of the epithelial variety.

In the first and second cases the bones were not involved, but in the third the cancer penetrated the tibia and destroyed almost the entire depth of the bone; so much so that one time, when the man jumped off a wagon, he heard a crackling sound and felt that something yielded. Fracture did not occur, but infraction of the bone did take place.

In answer to a question, Dr. Gerster said that the exophthalmos in his first case was due to a cancerous tumor in the posterior part of the orbit, and there was no evidence of communication with the cranial cavity, although there were metastatic deposits in the brain. The optic nerve, however, was not examined.

DR. JOHN H. RIPLEY presented a specimen of

EPITHELIOMA OF THE LIP—SPONTANEOUS HEALING OF THE ORIGINAL LESION,

with the following history:

In June last he saw, with Dr. Burton, G——, an Irishman, sixty-seven years old, supposed to have epithelioma of the lip. He found the patient, a tall, thin, feeble old man, suffering from a lozenge shaped superficial ulcer, about an inch long in its longest diameter, situated in the vermilion border of the lower lip, near the centre. The edges of the sore were indurated, and the secretion from it thin and watery. The sublingual glands were apparently enlarged.

The patient stated that about three years before he first noticed a slight fissure of the lip, which troubled him a great deal, with a burning pain, and which did not heal, but remained in about the same condition for a year. It then gradually enlarged, until it resulted in the ulcer which he saw. From the locality of the sore, its long duration and peculiar history, the submental infiltration, and the age of the patient, Dr. Ripley supposed it was epithelial cancer. There was no history of cancer in the family, and no evidence of syphilis in the patient. Considering his general condition and the fact that one lung was very much crippled by chronic pleurisy, and that both were the seat of chronic vesicular emphysema, he did not think an operation advisable.

In September he saw the case a second time, and found that the infiltration below the jaw had increased very much, and now extended around both sides so as apparently to involve both submaxillary glands. The ulcer remained about the same. In January, 1881, he saw the case a third time. The ulcer on the lip was entirely healed, and had been since Christmas, but the secondary deposits had increased, and spots of softening were felt in the right sublingual and left submaxillary regions. In February rupture occurred at both these points, with the subsequent escape of thin, offensive, purulent matter.

During this present month he had seen the case several times. The ulcer still remains healed, a linear cicatrix with puckering of the adjacent parts only marking the site of the original lesion. In-

filtration of the parts below, however, is progressing, and the destruction of tissue has continued. In the right sublingual region a deep, crater-like ulcer exists, the size of a copper penny. In the left submaxillary region there is a tumor as large as a pullet's egg, having several small sinuses leading into its interior, and besides these openings there are two large, angry ulcers at its summit. The treatment of the case, until within a couple of weeks, has been of the most simple and primitive kind. Locally the patient was in the habit of keeping a small piece of dampened white paper over the ulcer of the lip. Constitutionally, a cough mixture was being taken. No other treatment. The specimens, clipped from the ragged edges and interior of the ulcers, were examined microscopically by himself, and believed to show the characteristics of epithelioma. They were subsequently examined by Drs. Janeway, Satterthwaite, and Hegeman, with the same result.

Dr. Ripley remarked that he presented the case as the second in which he had known a primary cancerous ulcer to heal. The first was reported by Dr. Beverley Robinson, and was a case of epithelioma of the larynx. A case had been reported in Holmes' system of surgery, but Dr. Ripley thought the diagnosis was doubtful.

Dr. Gerster asked Dr. Ripley if he was sure that the ulcer was completely healed, and that the cicatrix would not show a cancroidal condition.

Dr. Ripley answered that it was to all appearances thoroughly healed and the lip was supple.

Dr. Howe remarked that the fact that a wound heals by first intention shows that there is no cancerous tissue at the point where the union has taken place.

The President thought that that point had been decided otherwise.

Dr. Briddon had seen the process of repair and the process of cancerous destruction going on in the same ulcer at the same time.

Dr. Howe remarked that the process of repair did not go on in the midst of cancerous tissue.

Dr. Briddon remarked that, in amputation of the breast for cancer, it was rare that the surgeon went completely outside of the cancerous infiltration, and yet the process of repair went on perfectly.

Dr. Howe said perfect union was strong proof that there was no cancerous material in the edges of the wound.

Dr. Briddon said that he had seen carcinomatous tumors slough and cicatrize, the scars remaining apparently sound for varying periods of time, but, in all the cases he had observed, the disease returned; in one case the process of necrosis occurred twice in the same place.

With reference to the question under discussion, he had seen the process of destruction and repair going on side by side, at the same time, in epitheliomatous patches, but he did not remember to have seen a case of complete repair, save where the parts had sloughed after the application of some destructive agent.

Dr. Gerster had seen cases in which the ulcer had healed and remained so for months, and he thought it was a fact that had been stated by surgeons that the same thing had occurred in cancer of the breast. With reference to Dr. Howe's statement that cancerous tissue is unable to form a cicatrix, he remarked that such tissue did not consist of cells alone, but of connective-tissue elements, and where the latter existed in abundance there was a great tendency to the formation of a cicatrix.

The President asked Dr. Beverley Robinson whether the case of epithelioma of the larynx which he had reported remained cured.

Dr. Robinson replied that the patient had died. The ulcer in the larynx, however, remained healed.

Dr. Ripley could account for the healing by the fact that cancerous deposit had occurred in another part of the body.

Dr. A. R. Robinson thought that Dr. Ripley's case could be explained in a simple manner, namely, that it was a case of epithelioma in a mild form, which gave rise to secondary deposit, and at the same time the primary ulcer healed. Certainly such cases were not difficult to cure, and he thought that it was not unusual for death to occur in consequence of secondary deposits after the primary lesion had healed. The case received treatment, and he would regard it in the same light as though excision had been performed. Epithelioma of the face and lip can be cured.

Dr. Ripley said that in the case he had reported there was practically no treatment. Moreover, he thought that epithelioma of the lip and face had not been cured so that the patient was not liable to its return.

The President added his testimony with reference to cure in many of these cases of cancer if the connective tissue is greatly in excess of the cellular elements—the former squeezing the latter to death, and destroying the ulcer in that way. Sometimes the connective tissue was made to preponderate by the use of the cautery or caustic paste. He had known of cases being cured—that is, the primary lesion healed by the use of poultices of various herbs, and nothing but a smooth surface remained. That the disease returned ultimately he believed was true.

Dr. A. R. Robinson had seen several cases in which complete cures, so far as known, had been effected by local treatment. Anything which would produce an acute inflammatory process might give rise to connective-tissue proliferation, which would swamp the cellular elements and be followed by cicatrization.

Dr. Delavan, on behalf of Dr. Clinton Wagner, presented a

DERMOID TUMOR OF THE PHARYNX.

Patient aged twenty, Irish, single, domestic. Previous history good. No heredity. Stated that two weeks before operation she first noticed something wrong with the throat, and the trouble had grown rapidly worse. On examination, patient is a well-developed, healthy girl, with no signs whatever of any diathesis; mouth, tongue, soft palate (anteriorly), tonsils and pharynx normal, with the exception of a slight amount of pharyngeal catarrh, and the following extraordinary appearance. Upon the left side of the pharynx is a foreign body, which hangs downward from behind the velum a distance of seven-eighths of an inch, and extends from near the median line toward the left nearly to the lateral wall of the pharynx. The surface of this body is pale, and no blood-vessels are apparent upon it, in which it offers a striking contrast with the neighboring parts. The body is freely movable, and flattened in its antero-posterior diameter to such an extent that, while touching the posterior wall of the pharynx, it does not project anteriorly beyond the middle of the tonsil. Rhinoscopic examination demonstrates clearly that the body is a tumor, springing by a pedicle from the soft palate. Its attachment corresponds with a space located one-fourth of an inch to the left

of the median line midway between the lower margin of the velum and the lower border of the left nasal fossa. Dr. Wagner believing, from the history of the case, that the growth was recent, and likely to increase rapidly in size, and that, from the position and size of its pedicle, its removal could be accomplished without much difficulty, decided to operate upon it at once. The operation consisted essentially in dragging the tumor downward into the pharynx as far as possible, and then dividing the pedicle with a knife. This apparent simple procedure was attended with unexpected difficulty, for, instead of yielding readily to the knife, the tumor proved to be so dense and resisting, that great force was required to effect its separation. Copious hemorrhage followed, but was speedily checked by ordinary methods. The portion of the tumor removed, upon careful examination and dissection, presented the following characteristics: it was an irregular, ovoid mass, flattened from before backward, about seven-eighths of an inch broad, three-fourths of an inch in its vertical diameter, and from three-sixteenths to one-fourth of an inch in thickness. It was thickest at its margins, while its middle and anterior surface was slightly concave. Its surface was covered with an integument bearing no resemblance whatever to mucous membrane, and furnished with fine, but distinctly visible hairs. Beneath the integument was a layer of fat, and, beneath the layer of fat, two plates of cartilage. Further dissection demonstrated the existence of three cartilaginous plates, two large and one smaller. These were curled outward at their margins, which tapered off to a thin and serrated edge. The plates were separated by fibrous tissues. In all its essentials the tumor presented an extraordinary analogue to the helix of a normal ear.

The tumor was hardened in absolute alcohol, and microscopic sections made completely through its vertical and transverse diameters, and when stained with carmine and mounted in Canada balsam, gave under the microscope the following appearance. The tumor was covered with a true skin, complete, with one exception, in all its essentials, as follows: first, a delicate, but clearly marked layer of horny epithelium, covering a thick rete Malpighii, into which there extended a large number of simple papillæ; beneath this a corium, containing many hair-follicles, which in most instances were provided with a delicate, non-pigmented, but otherwise perfect hair. Into the majority of the hair-follicles there opened a large, sebaceous gland. Both the sebaceous glands and the hair-follicles were typical and very abundant. Beneath the integument was a thick layer of fat, in which were scattered small bundles of fibrous tissue. Then followed a tolerably dense layer of fibrous tissue, which covered a thick plate of reticular, elastic cartilage. This plate adjoined another similar plate, and between them was a thick mesh-work of fibrous tissue, which contained many blood-vessels, and formed in reality the central part of the tumor.

The story of the patient as to the recent origin and rapid growth of the tumor was evidently incorrect. Although never before observed, it was without doubt congenital. Diligent search through all of the available literature bearing upon this case has failed to disclose a single reference to any such growth as the above. By an extraordinary coincidence, the following appeared in a report of the Pathological Society of London, published in the London *Lancet* of April 9, 1881, p. 581:

"Dr. Hale White showed a specimen of dermoid tumor of the soft palate, from a child three years of age, who had had some difficulty in swallowing. The uvula was much hypertrophied and lay in front of the tumor, which apparently sprang from the upper surface of the soft palate; the tumor was two inches in height, and had a wide base; it was freely movable, and was removed by Mr. Morrant Baker. It was found to be soft in consistency, except on one surface, where a plate of cartilage existed. Microscopically it reproduced all the cutaneous structures —epidermis, papillæ, corium, fat-cells, but no elastic fibres. There were also many hairs lodged in follicles, into each of which a single sebaceous gland opened. The plate of cartilage was incrusted by a dense layer of fibrous tissue; its matrix was very scanty and fibrillated, the outer layers of the cartilage being composed of nucleated stratified cells. Dr. White referred to a similar growth from the basilar process of the occipital bone, recorded by Dr. Abraham in the *Journal of Anatomy*, vol. xv., and to one on the palate of a new-born child, described by Dr. Kidd in 1856. As to the origin of the tumor in the present case, it might have grown in connection with the Eustachian tube; but its epiblastic nature was sufficiently accounted for by its occurrence in front of the junction of the hypoblast and epiblast. It might be an instance of "reversion," for in the rabbit there occur in this region four tufts of hair, two above and two below. Mr. Rushton Parker had lately seen a similar dermoid growth removed by Mr. Bickersteth from the pharynx of a child and depending from behind the soft palate."

Dr. Heineman presented a specimen, removed from the body of a man about forty years old, which illustrated

COMPLETE INGUINAL REDUCIBLE EPIPLOCELE, WITH AN UNDESCENDED TESTICLE BEHIND THE PERITONEUM AND ALONGSIDE THE RING.

The peculiarity was that when the omentum was in the scrotum it gave a feeling as though the testicle itself was there.

Dr. Heineman also presented, in behalf of a candidate,

A LIVER WITH THE LOBES TRANSPOSED.

Dr. Beverley Robinson presented a

FOREIGN BODY REMOVED FROM THE NOSE.

The history was furnished by Dr. G. J. Moser.

J. R——, cabinetmaker, aged fifty-seven, was attacked on March 5, 1881, with a severe epistaxis. He called in Dr. D. T., to check the hemorrhage. Dr. T., not being capable of arresting the bleeding, sent for Dr. K. The latter, on his arrival, made a tampon by tying a piece of sponge about the size of a walnut to a single string, and plugging the posterior nares in the usual manner, thus arresting the bleeding.

The patient remarked to the doctor that he did not leave a string in his mouth, in order that the sponge might be removed in a few days, as had been done heretofore by another physician. The doctor answered—"We don't always do so, because the patient might bite the string off, and it would feel very unpleasant in the throat." The case progressed favorably until March 8th, when Dr. T. endeavored to remove the plug by passing his finger into the patient's pharynx, but failed. He then passed a flexible bougie through the patient's inferior meatus, reached the pharynx, but did not dislodge the sponge.

On March 12th he repeated the effort, and with

the same result. He then cut the string which depended from the left nostril, close to the man's nose, at the same time telling the patient that the sponge would rot out in time.

On March 28th, Dr. Moser was called in and found the patient with his head bent over a basin, the nose discharging pus very freely, the offensive odor of which made it almost impossible to approach him. He passed a No. 8 flexible bougie through the inferior meatus, but failed to remove the plug. He then washed the pharynx with a posterior nares syringe, and employed a Davidson's syringe to dislodge it from before backward, but this attempt proved futile.

On April 1st, Dr. Beverley Robinson saw the patient with him and passed a large steel sound through the lower meatus, which failed. He then tried to grasp the hidden treasure by the use of different curved forceps, and also with his finger, but with no better result than at first.

On April 3d, Dr. Moser discovered the short string attached to the sponge depending about a quarter of an inch from the patient's nose. To this he attached a longer string, which he fastened to a flexible bougie. He then introduced the bougie through the lower meatus into the pharynx, and drew it through the mouth. The long string followed, and with considerable traction the sponge was removed, which caused the patient entire relief from his suffering.

Dr. Robinson thought the reason why he did not succeed in removing the sponge was because it had become wedged into the middle meatus behind.

MULTILOCULAR OVARIAN TUMOR—ACCIDENTAL INJURY CAUSING AMELIORATION OF THE SYMPTOMS—DEATH FROM CONSTRICTION OF THE INTESTINES AND GENERAL PERITONITIS.

The President presented a multilocular ovarian tumor that had been removed, *post-mortem*, from a lady, a patient of Dr. A. S. Purdy, at whose instance he had made an autopsical examination. The growth was first observed in 1864, when Drs. McComb and Peaslee assumed charge of the case. Nine years later, when Dr. Purdy was first called in consultation, three cysts were quite plainly recognizable. In the following year, 1874, a singular accident occurred, which had a marked influence on the after-history of the patient. Crossing the street one day, she was run over by a horse, the animal planting one foot squarely on the centre of the largest cyst. After removal to her home, it was found that the cyst had been ruptured. Acute peritonitis then set in, but the lady recovered in a great measure her health and strength. Subsequently operative interference was urged, at various times, but consent could not be obtained. Death took place in May of 1880, or 16 years after the first symptoms had been noticed. The final issue was brought about by general peritonitis in conjunction with constriction of the intestines, the latter resulting from the combined agencies of increasing growth in the tumor and the contraction of fibrous deposits due to peritonitis.

The special points of interest were, in the first place, the prolonged duration of the disease, for, according to T. Stafford Lee, the great majority of these cystic tumors terminated fatally within two years, if left to themselves, and Dr. John Clay, in giving the natural duration in 175 cases before the introduction of ovariotomy, found only fifteen in which it had been more than ten years, and further, according to Thomas Lee's statistics, showed also that in 94 out of 123 cases the average duration was less than five years where no certain surgical treatment had been adopted.

In the second place there had been amelioration of the symptoms, and a decided check given to the disease by an accidental injury, at which time singularly enough the tumor interposed and probably saved the patient's life. Finally, the cause of death was to be attributed to two conditions: one, the constriction of the intestinal base by which its functional activity was restricted; and the other, the alternating attacks of acute or chronic peritonitis that had existed during the latter years of her life.

Dr. Ripley referred to a case of ovarian tumor in St. Francis' Hospital, under the care of Dr. Gillette, who was about to operate, when the sac ruptured into the intestine, and the patient died.

Dr. Briddon remarked that rupture into the bowel was rare with ovarian tumor. He thought that the indication, in cases such as reported by the President, was immediate ovariotomy. For, if the patient should struggle through the peritonitis, the evil effects of the adhesions should be taken into consideration, and the operation be performed before peritonitis set in.

Dr. Sell referred to a case in which extensive adhesions resisted, but ovariotomy terminated successfully.

The society then went into executive session.

## MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

*Stated Meeting, May* 23, 1881.

Dr. A. E. M. Purdy, President, in the Chair.

THE PROPER LIMITATION OF EMMET'S OPERATION FOR LACERATION OF THE CERVIX UTERI.

Dr. Charles Carroll Lee read a concise paper on the above subject, in which he alluded to the unjust obloquy thrown upon the operation because it has been abused; to the words of commendation which had been spoken for it by Sims, Peaslee, Barker, and Thomas; and then proceeded to the consideration of conditions contraindicating its performance, upon which Dr. Emmet, as he thought, had not expressed himself sufficiently clearly and forcibly in any of his publications.

*First.*—The existence of peri-uterine cellulitis contraindicates the performance of Emmet's operation.

*Second.*—The existence of pelvic peritonitis is a contraindication to its performance.

*Third.*—When any decided inflammation exists about the uterus, or so long as any tenderness can be detected in the neighboring connective tissue it is unsafe to operate, and it is equally contraindicated when endometritis or cervicitis exists.

*Fourth.*—It is contraindicated by other forms of disease, general forms of ill-health (such as extreme anæmia, chlorosis, constitutional syphilis attended by vaginal lesions), excepting those conditions which it is reasonable to suppose depend upon the laceration itself.

The important question is, as has been clearly stated by Dr. Thomas: How often do such lacerations produce results which have an important bearing on uterine pathology? Upon the recognition of this fact the necessity for operative interference should depend; and if, without reference to their pathological influences, all cervical lacerations are closed

with sutures, many women will be exposed to unnecessary surgery.

In proper cases, nothing had convinced Dr. Lee that any form of caustic or cautery is to be preferred to the simple surgical operation. After urging a more careful supervision of the lying-in state than generally prevails, maintaining that a woman should never be discharged from the obstetrical list until it has been determined whether or not laceration of the cervix or perineum exists, and if present not until they have been repaired, Dr. Lee reached these conclusions:

*First.*—When cases of lacerated cervix present themselves, never consent to operative treatment until all traces of pelvic inflammation have been removed.

*Second.*—Be guided, in determining whether or not an operation is necessary, solely by the pathological import of the laceration and its probable influence upon the pelvic tissues.

*Third.*—In the treatment of cervical laceration, adhere resolutely to trachelorrhaphy until time shall yield us a more sure and better method than that devised by the patient ingenuity of Dr. T. Addis Emmet.

To Dr. M. A. Pallen, Dr. Lee gave the credit of being the first to close a lacerated cervix with sutures immediately after the occurrence of the accident.

The discussion was opened by Dr. T. Addis Emmet, who regarded Dr. Lee's paper as very timely, for, without doubt, the operation had been performed too often, and it was time that some limitation should be placed around it. He thought that the line could be drawn even closer than had been done by Dr. Lee, and he would say that the laceration in itself does no harm and should receive no treatment unless some bad results come from it. If it extends into the connective tissue of the pelvis, more or less of pelvic inflammation is sure to occur. He thought that it might be properly stated that if there has been no cellulitis and the accident occurs, the rent will heal and give rise to no trouble. The bad effects come from persistent cellulitis.

When he read his first paper, to which Dr. Lee had referred, he stated, in speaking of the operation of division of the cervix for dysmenorrhœa and sterility, that his objection to it was because it was liable to be followed by a gaping of the flaps and eversion extending into the uterine canal. At that time he supposed the eversion was incident to the process of fatty degeneration, that the posterior lip naturally impinged against the posterior vaginal wall, gradually flattened, became a source of irritation. and after it had existed a little time, all appearance of the division or laceration became lost. But for some time past he had been studying cases with reference to this particular point, and had reached the conclusion that the rolling out is due to inflammation of the connective tissue of the pelvis obstructing the circulation, and in that manner causing eversion of the lacerated cervix; and his reason for so believing was that when he patiently treated the cellulitis, and cured that, the operation had not been required in one in ten cases, and, furthermore, relapses had seldom occurred in cases thus treated. It is important to recognize the existence of pelvic inflammation however slight it may be, and in those cases it cannot be said whether or not the operation will be necessary until it can be determined whether or not the patient can be cured otherwise. When he read his paper in 1874, he directed attention to the propriety of operating while pelvic inflammation existed, and said: "So long, however, as there can be detected, by pressure from the finger, any tenderness in the neighboring connective tissue, it is not safe to operate, as we may feel satisfied fully that a certain amount of cellulitis has previously existed, and a condition is still remaining which would require but slight provocation to re-establish the inflammation, were we to disregard this warning."

The successful treatment of uterine disease depends upon the amount of indurated tissue remaining. When the rent has extended beyond the cervix into the connective tissue of the pelvis, a cicatricial mass frequently forms, which acts as a foreign body. For twenty years or more he had recognized the fact that when the cervix is indurated the patient is liable to reflex disturbances, neuralgias, etc., and not only that, but persistent anæmia is frequently produced, which will not yield to any treatment until the woman has passed through the menopause. Years ago, nitrate of silver was used more freely than at present, and so also were cases of neuralgia dependent upon uterine disease more numerous than now. Formerly Sims amputated the cervix for the relief of some of these cases, but that did not seem to work well, and Dr. Emmet was led to simply shave the cervix, draw the vaginal tissue over it, which proved equally successful. In many cases the neuralgia was removed, and general nutrition greatly improved.

It was true that his explanation had not been generally accepted, but the clinical fact, however, could not be refuted, that if cicatrical tissue in the cervix is removed, and, by any means that cervix is restored to a soft, healthy condition, the exciting cause of neuralgia and anæmia also is removed. When a patient comes to him suffering from neuralgia, he wastes but little time in preparatory treatment, except to cure the cellulitis, but goes at once to the limit of the laceration, and removes all cicatricial tissue. His explanation of the effect upon the general nutrition of the patient in these cases was by the effect produced upon the sympathetic nervous system. His advice was to first remove the cellulitis as far as possible, and a large number of cases would not, when that was done, need an operation. If cicatricial tissue exists in the angle of the laceration, and the woman suffers from reflex disturbances—and any organ in the body might be so affected—an operation is necessary.

If cicatricial tissue is found hardening the surface of the cervix, and no anæmic or other symptoms exist, let the woman alone, but she must be watched. A mere laceration need not be closed unless it gives rise to symptoms. Usually, when the cases are studied carefully, evidence of blood-poisoning at the time of parturition will be found, and perhaps has prevented the healing. If care is taken after confinement, to keep the parts *clean*, probably in most cases healing will occur spontaneously.

Dr. M. A. Pallen said that in 1868 he closed a lacerated cervix by what is known as Emmet's operation, published an account of it in July of the same year, in the *St. Louis Medical and Surgical Journal*, and was not aware, at the time, that the operation had ever been performed. Since then he had not seen it performed by any one, except Dr. Henry Goldthwaite, and therefore his conclusions were the result of his own observation. To Dr. Emmet was due all the benefits which the profession had received from the operation.

Dr. Lee had placed him upon record as the first who had stitched the torn cervix at the time of the occur-

rence of the accident. In 1869 he made his first operation, and published it in the *Richmond and Louisville Journal* in 1874, although the paper was written in 1872. Since that time he had performed the operation several times.

Again he wished to place himself on record. In a paper read in 1867, and published in the "Transactions of the American Medical Association," he stated that no operation was ever to be attempted about the cervix uteri in cases in which there were any traces whatever of pelvic cellulitis. Dr. Emmet had pointed this out also, thoroughly, in his work on Gynecology. Dr. Pallen took issue with Dr. Lee and also Dr. Emmet as to the propriety of waiting before performing the operation. It is a good rule in surgery, and he believed that it is applicable here, to mend all fractures of tissue, whether skin, bone, or mucous membrane, as soon as practicable, and the rectification of the fracture is regarded as a preventive against future difficulty. He had not seen a case in which he regretted having performed the operation immediately, but he had seen some in which he had regretted that he had not performed it. If the laceration was sewed up, primary hemorrhage was avoided. The shock from the operation was slight. If it was well done, absorption of septic material was avoided; and if the parts were kept properly cleansed, union was prompt and satisfactory, and the result would be good in a very large majority of cases. Latterly he had become convinced that the laceration comes from too prolonged labor—too great delay, instead of too rapid labors or dragging the child through with instruments.

Dr. Paul F. Mundé thought that doubtless the operation has been performed improperly, but perhaps not by specialists. Since he read his paper on the subject, *three* years ago, he had examined 569 women who had borne children, and in 171 laceration of the cervix was found, a much larger percentage than in the group of cases first reported, consisting of 700 women who had borne children, with 119 cases of laceration of the cervix. The total was, 1,269 women, and 229 cases of laceration, or 22.6 per cent.

Dr. Pallen said he had found laceration in 45 per cent. of women who had borne children.

Dr. Emmet had found it in a little over 33½ per cent.

Dr. Mundé thought that if the laceration was sufficient to permit eversion of the cervix the operation should be performed. Large lacerations should be closed, even though they be cicatrized. He then spoke of various indications for performing Emmet's operation, as cervical catarrh, menorrhagia, or metrorrhagia, cervical endometritis, chronic ovaritis, areolar hyperplasia, reflex neuralgia. If the cervix was cicatrized over *smoothly*, he doubted the propriety of the operation. Anæmia and tuberculosis were not contraindications in all cases. He agreed with Drs. Lee, Emmet, and Pallen with regard to the importance of avoiding the operation when pelvic inflammation existed, when the slightest tenderness was present, provided he had not given the patient sufficient time to get well of such inflammation. He believed that the operation was not contraindicated in all cases, although the vaginal walls might not be entirely soft; but he would not make that a rule.

Dr. William M. Polk drew attention to the lack of unanimity of opinion, among the speakers by whom he had been preceded, with reference to when the operation should be performed, and, to a certain extent, as to the cases in which it should be resorted to. If he understood Dr. Pallen correctly, the operation was performed at the time of parturition, for the purpose of arresting hemorrhage, and doubtless it was proper that it should be done under those circumstances. But he took issue with Dr. Pallen on the claim that immediate closure of the laceration protected the woman from septic poisoning. The claim had been that the edges of the wound should be closely approximated, and if not so closed, open vessels would facilitate absorption of septic material; and besides, the woman would be saved from the secondary operation. Dr. Polk granted that, if the edges of the wound could be approximated, as in the secondary operation, the object sought for would be obtained; but, as a matter of fact, it was exceedingly difficult to accomplish that, even with the best assistants and light, and under the most favorable circumstances; therefore, in most cases probably, the end desired would not be secured. That being the case, he thought that the patient should be spared the inconvenience of the primary operation; and that the secondary one would answer all purposes, except, perhaps, in certain cases of hemorrhage. He thought that many of the indications mentioned by Dr. Mundé could be grouped under a single head—namely—subinvolution.

Dr. Polk then spoke of the possibility of preventing laceration of the cervix uteri in labor. Of course, all the graver operations in midwifery were quite certainly accompanied by more or less laceration of the cervix. But in ordinary labors, he believed that *premature rupture of the membrane was a prominent cause of laceration of the cervix, and should be avoided.*

Dr. Putnam Jacobi remarked that the fact was interesting, that it was not necessary to have merely a cicatrix in order to have reflex disturbances developed, but that it must be a cicatrix involving the mucous membrane. The whole pathology of the lesion went to confirm the view that the starting-point for the reflex irritation was somewhere in the mucous membrane; but she believed that we must look to the cerebro-spinal, and not to the sympathetic nervous system, for the explanation of the reflex phenomena manifested.

Dr. W. Gill Wylie believed that, if the uterus was normal, laceration of the cervix would not occur, even if instruments were used in effecting delivery; but with an abnormal condition of the cervix, rupture almost always occurred. He then referred to cases in which he had dilated the internal os, for the purpose of curing the vomiting of pregnancy, and with excellent results; and in those cases, rupture did not take place during labor. He did not believe that the disturbances regarded as reflex were due simply to pressure produced by cicatricial tissue in the angle of the laceration; because that tissue might be softened and yet all the symptoms remain. The softening, however, leaves the lips of the laceration in a condition unfavorable for subsequent operation.

The society then adjourned.

---

Crude Petroleum in Phthisis.—Dr. C. S. Strothers (*Medical and Surgical Reporter*) adds another to the list of those who claim the best results from the use of petroleum in phthisis. He has given it in four-grain doses, in pill or capsule. He "has found it far superior to cod-liver oil in phthisis, as its effects have been not only to relieve the cough, but to improve the appetite and produce an increase in the waste of the body."

# Correspondence.

## GYNECOLOGICAL OPERATIONS — THE METHODS OF PROFESSOR MARTIN, OF BERLIN.

To the Editor of The Medical Record.

Sir: The method of performing operations on the uterus, vagina, and perineum, practised by Dr. August Martin, of Berlin, seems to present some advantages when compared to that very commonly practised.

Instead of keeping the surfaces clear of blood by sponging and occasional irrigation, he employs constant irrigation. A can holding several gallons of a solution of carbolic acid stands at the side of and above the operating-table. By means of a rubber tube with a gutta-percha tip, water is constantly conveyed from the reservoir to the wound. The patient lies in the lithotomy position, with her pelvis resting upon a cushion, which is covered with a rubber cloth. This cloth hangs down over the end of the operating-table, and into a large tin receptacle standing upon the floor between the legs of the table. The operator protects himself by wearing a rubber apron, the ends of which also hang into the tin receptacle. The constant stream of water serves not only thoroughly to disinfect the parts, and immediately wash away any septic discharge that may be present, but also to check the bleeding in some degree, since the water, being at the temperature of the room, is slightly cooler than the body. Should the bleeding be considerable from any particular point, this is commonly controlled by pressure of the assistant's finger until the operation is completed, and then all bleeding is effectually checked by the stitching together of the wounded surfaces. Ligatures are almost never used. The strength of the carbolic solution used is about two per cent. for ordinary cases, when there is no especially septic element present, but in cases of cancer or foul discharge the solution is about five per cent.

The material used for sutures is always silk, since catgut yields too soon to withstand the tension brought upon the adjacent surfaces, besides being very hard upon the fingers of the operator when so many stitches are necessary as in these operations.

For chronic metritis, accompanied by endometritis and endocervicitis, Dr. Martin operates as follows: The patient is placed in the lithotomy position, and the vagina is held open by a posterior and lateral spatulæ. The uterus is held forward by means of double musket-ball extracting forceps, which close with a catch. These are inserted into the anterior and posterior lips. The interior of the cervix and uterus are then curetted and thoroughly irrigated with the douche, the nozzle being inserted into the uterus. About three drachms of perchloride of iron are then injected into the cavity of the uterus, both to act as styptic and caustic.

The common sharp curette is not used for this purpose, but one made of steel, the ends being in the form of a half-cylinder, with the cutting edges dull and about two inches long. The lips of the cervix are divided from each other by an incision, extending to their point of union with the vagina. A wedge-shaped piece is then excised from each lip. Two incisions are made extending from one side of the lip to the other, and including a considerable portion of the tissue of the cervix, which is usually hypertrophied. Silk sutures are then inserted from the outer surface of the cervix into the cervical canal in the anterior lip, and in the reverse direction in the posterior lip, so that the refreshened surfaces of each lip are united to each other, and then the two lips of the cervix are united at their extremities. The sutures are placed closely together, so that there is no bleeding, and are cut off short. When completed, the cervix should resemble in shape and size a normal cervix, and the os should be easily pervious to the sound.

In cases of prolapse of the uterus, the curetting of the uterus and amputation of the cervix immediately precede the operation of colporrhaphy, since these serve to produce a reabsorption of the usually hypertrophied tissues and a consequent decrease in the weight of the uterus, and its tendency to force downward the flow of the pelvis. Anterior colporrhaphy is performed by removing an oval piece of mucous membrane, about one and one-half inch wide, reaching from the tubercle just behind the urethral opening backward to the cervix.

The part removed has only the thickness of the mucous membrane, and the freshened surface is carefully trimmed with scissors, so as to remove all ragged tissue, and make healing by first intention more certain. Silk sutures, passing beneath the freshened surface, are inserted one-fourth inch from one another, so that the deep, as well as the superficial parts, are included, and thus brought in apposition; and between these, superficial sutures are inserted, so that the coaptation of the surfaces is exact.

Next, posterior colporrhaphy is performed, not by removing a single oval piece of mucous membrane from the posterior central surface of the vagina, but by removing two pieces on either side. The reason for this is that the posterior wall, being thicker than that at either side, makes a good support for the uterus after the operation. Also, a transverse section of the vagina on the cadaver shows that there are two folds in the vagina, at either side of the posterior column, so that the posterior wall of the vagina has a projecting thick central portion, with two furrows on either side. To remove the superabundant tissue, an oval piece of mucous membrane, about one inch in width, is removed, first from one side of the central column, and then the wound is united by deep and superficial silk sutures, as in the anterior operation. A similar operation is then performed upon the other side. The column of mucous membrane left between the two sides is about one inch wide. The two pieces removed extend from either side of the cervix above, down to the perineum. Last of all, the perineum is freshened, the freshened surface extending about half the width of the vagina forward, and the surfaces are so united that the sutures form a single straight line, extending outward from the extremity of the two lines of sutures, uniting the two lateral operations. The patient is placed in bed, the knees are tied together, and she must lie perfectly quiet on her back, without attempting to move herself or sit up, for three weeks; and a great degree of the success of the operation depends upon the quietness of the patient. The patient is not catheterized, unless she cannot pass her water voluntarily, and if the bowels do not move during the two days succeeding the operation, a dose of castor-oil is given. The diet does not differ from that given to other surgical patients, since defecation does not seem to be prejudicial to the healing of the operation. After micturition, the parts are cleansed by running water over them into the bed-pan. This

is done at least three times daily, but not much water must be used, since it seems to prevent healing. No water is injected into the vagina.

The part is not disturbed and no stitches are removed until the end of the third week, when the superficial sutures are removed, while the deep ones remain for from four to six weeks, being removed a few at a time. No tension is exercised upon the parts in order to remove the sutures.

The results of Dr. Martin's operations have proved highly satisfactory. With patients who lie still the healing is almost universal. If patients are very restless and do not lie quietly, healing of the perineal portion is sometimes incomplete, in which case the unhealed portions must be operated upon a second time. The vaginal part of the operation has never failed to heal. Since the method of irrigation has been practised Dr. Martin has operated upon one hundred and forty cases of prolapse and amputated over three hundred and fifty cases of hypertrophied cervix, and in this number but two patients have died, one of prolapse and one of hypertrophied cervix.

The relief afforded the patients by both operations is very great. Not only the immediate results are good, but complications, such as bleeding, parametritis, etc., are relieved. In the last one hundred and fifty cases there has not been a single secondary hemorrhage. If the healing has been complete, the uterus does not again tend to descend; but if incomplete and there is again a tendency to prolapse, the unsuccessful portion of the operation must be repeated.

This radical method of treatment practised by Dr. Martin is preferred in most cases to other means, since its results are more complete and permanent. Pessaries are not only filthy, but tend to distend the vagina, and, though enlarged often, fail at length to retain the uterus. Thus, if astringents fail to control the prolapse, and there are no especial contraindications to an operation, such as inflammation, etc., the operation is performed without delay.

The opportunity for seeing plastic operations in gynecology with Dr. Martin are, so far as I know, unsurpassed in Germany. During the year he has about one thousand four hundred cases, and a daily attendance upon his polyclinic of from twenty to forty, and in his private clinic from one to four operations. Four or five gentlemen are allowed to see the operations in his private clinic and to examine the patients in his polyclinic. No one attending the operation is allowed to have anything to do with pathological or anatomical material or other operations where he might come in contact with septic material.

D. P. A.

BERLIN, GERMANY, June, 1881.

READY METHOD OF PREPARING FOMENTATIONS.—Take your flannel, folded to the required thickness and size, dampened quite perceptibly with water, but not enough to drip, and place it between the folds of a large newspaper, having the edges of the paper lap well over the cloth, so as to give no vent to the steam. Thus prepared, lay it on the heated surface of the stove or register, and in a moment steam is generated from the under surface, and has permeated the whole cloth sufficiently to heat it to the required temperature. This method is often very convenient and efficient where there is no opportunity to heat much water at a time.—*Michigan Medical News.*

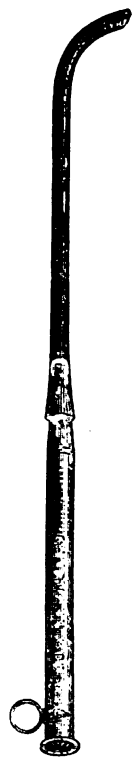
# New Instruments.

## A NEW EUSTACHIAN CATHETER.

By SAMUEL SEXTON, M.D.,

NEW YORK.

AN apology is not required, I trust, for offering a Eustachian catheter, the introduction of which into the guttural mouth of the Eustachian tube is less painful than those made of either metal or vulcanite. Flexible instruments have been devised, as is well known, but none have possessed sufficient merit to retain a permanent place in the aurist's armamentarium. So far as is known to me, M. Deleau was the first to recommend a flexible catheter, the description of which may be found in his "Traité du Cathétérisme de la Trompe d'Eustache," etc., p. 115. Paris, 1838. But the pain caused in withdrawing the stilette of Deleau's instrument led to its abandonment. It occurred to the writer that a catheter made of soft rubber, but sufficiently firm to retain the necessary curvature of the beak, could be used without a stilette, thus overcoming the principal objection to its adoption.



A catheter of this kind is shown in the wood-cut. The part A is a canula of German silver, nickel-plated; it is eight and a half centimetres in length and about one-half of a centimetre in diameter. The soft-rubber portion, C, is eleven and a half centimetres in length. The cut is about one-half the size of the instrument. The metallic portion affords a firm handle for holding the instrument during its introduction and for subsequent manipulations.

Owing to the softness of its pharyngeal end, the catheter may have a much greater curvature than one of inflexible material, thus permitting of its secure lodgment in the mouth of the Eustachian tube when the necessary manipulations of the surgeon have brought it in position.

In cases of lateral deviation of the nasal septum, with closure of one side, I have succeeded in introducing the catheter into either Eustachian tube while the instrument remained in the unobstructed meatus. I may here state that the smooth and soft finish of the rubber used by the maker of the instrument will allow of very free movements being made in the nasal meatus and vault of the pharynx without giving rise to irritation of these sensitive parts.

Several sizes of the rubber portion of the instrument may be employed, but I have as yet required only two in my own experience, one of them being five and the other seven millimetres in diameter. The thickness of the rubber is one millimetre. The beak is more tapering than is shown in the cut. The canula is tapering where it enters the flexible portion; in attaching the two parts the ring guide of the canula should correspond with the concavity of the curved beak. When the operator finds that the beak has engaged in the mouth of the Eustachian tube, as indicated by the diagnostic tube, it may be

more firmly secured in its place by gentle inward pressure. From some months' experience in using this catheter I believe it to possess the following advantages over other instruments:

It enables the surgeon to more easily perform the operation of Eustachian catheterism.

It is less painful to the patient.

It admits of greater cleanliness, each patient may retain possession of the soft rubber portion of the instrument which has been used in his case. The instrument is made by George Tiemann & Co. of this city.

Since writing the above, the author recalls the fact that an English surgeon, Cleland, introduced a flexible Eustachian catheter in 1731.

12 West Thirty-fifth Street.

## Medical Items and News.

The International Medical Congress.—The following daily programme has been issued as a provisional scheme:

*Tuesday, August 2d*, 10 A.M. to 6 P.M.—Registration of members and issue of tickets at the office of the Reception Committee, in the Royal College of Physicians, Pall Mall East. 3 to 6 P.M.—Reception of the members of the Congress by the Executive and Reception Committees at the Royal College of Physicians.

*Wednesday, August 3d*, 8 A.M. to 6 P.M.—Registration of members and issue of tickets at the Royal College of Physicians. 11 A.M.—First general meeting, St. James's Great Hall; address of welcome by the Chairman of the Executive Committee; Secretary-General's report; election of officers and constitution of the Congress; election of honorary presidents of the Congress; election of honorary presidents of the sections; inaugural address by the president of the congress. 3 P.M.—Meeting of the sections; constitution of the sections, and other business. 9 P.M.—Conversazione at South Kensington Museum (entrance Exhibition road), given by the English members of the congress to the foreign members.

*Thursday, August 4th*, 10 A.M. to 1 P.M.—Sectional meetings. 1.30 to 3.30 P.M.—Visits to hospitals—Guy's Hospital, London Hospital, St. George's Hospital, St. Mary's Hospital, St. Thomas's Hospital, Westminster Hospital. The medical officers and lecturers will be prepared to receive such members of the congress as may desire to visit these hospitals, and to inspect their schools and museums. 2 to 3.30 P.M.—Additional meeting-time for the sections. 4 to 5.30 P.M.—Second general meeting, theatre of the University of London; address by Prof. Maurice Raynaud, Paris: "Le Scepticisme en Médecine, au temps passé et au temps présent." 5.30 P.M.—Banquet given to a certain number of the members of the congress by the Lord Mayor of London, at the Mansion House.

*Friday, August 5th*, 10 A.M. to 1 P.M.—Sectional meetings. 1.30 to 3.30 P.M.—Visits to hospitals—Bethlem Hospital, Charing-cross Hospital, King's College Hospital, Middlesex Hospital, St. Bartholomew's Hospital, University College Hospital. The medical officers and lecturers will be prepared to receive such members of the congress as may desire to visit these hospitals and to inspect their schools and museums. 2 to 3.30 P.M.—Additional meeting-time for the sections. 4 to 5.30 P.M.—Third general meeting, theatre of the University of London; address by Dr. Billings, Washington, U. S., on "Our Medical Literature." 9 P.M.—Conversazione at the Royal College of Surgeons.

*Saturday, August 6th*, 10 A.M. to 1 P.M.: Sectional meetings. 4 to 7 P.M.: Reception of a certain number of the members at Kew Gardens, by Sir J. D. Hooker. 4 to 7 P.M.: A garden party will be given by Mr. and Mrs. Spencer Wells, at Golder's hill, Hampstead. 6.30 P.M.: The United Hospital Club will entertain a party of the members of the congress at dinner at the "Star and Garter," Richmond hill.

*Sunday, August 7th*, 10 A.M.—A service will be held in Westminster Abbey; sermon by the Very Rev. Dean Stanley, D.D., F.R.S. 3.15 P.M.: A service will be held in St. Paul's Cathedral; sermon by the Rev. Canon Liddon, D.D., D.C.L. 2 P.M.: The Royal Botanic Society's Gardens, and the Gardens of the Zoölogical Society, in the Regent's Park, will be open free to members on this and on every day of the week, on presentation of their tickets. The Royal Gardens at Kew may be visited on Sunday from 9 A.M. till sunset, and Hampton Court Palace and Gardens from 2 P.M. till sunset.

*Monday, August 8th*, 10 A.M. to 1 P.M.—Sectional meetings. 2 to 3.30 P.M.: Additional meeting-time for sections. 4 to 5.30 P.M.: Fourth general meeting, theatre of the University of London; address by Professor Volkmann, Halle. 6.30 P.M.: Dinner given to a certain number of the foreign members of the Congress by the worshipful master and wardens of the Society of Apothecaries in their hall in Blackfriars. 9 P.M.: Soirée in the Albert Hall, and the International Medical and Sanitary Exhibition, South Kensington.

*Tuesday, August 9th*, 10 A.M. to 1 P.M.—Sectional meetings. 2 P.M. to 3 P.M.: Fifth general meeting, theatre of the University of London. Address by Professor Huxley, F.R.S., D.C.L., London, "The Connection of the Biological Sciences with Medicine." 3 P.M.: Concluding meeting of the Congress.

After the concluding meeting the members, accompanied by their friends, will proceed to Victoria Station, for High Level Station (London, Chatham, & Dover Railway), where special trains will be in waiting at four o'clock, to convey them to the Crystal Palace. After a visit to the Palace and grounds, an informal dinner will take place in the concert room about seven o'clock.

Places of interest may be visited by members of the Congress, on conditions which can be ascertained at the office of the Reception Committee.

*Friday, August 5th*, 12.45 P.M.: Mr. John Penn will receive a certain number of the members of the Congress on board a special steamer at Charing-cross pier, in order to proceed down the river to Greenwich, and after luncheon there with Mr. Penn to visit the engine works of the Messrs. Penn, returning either by water or rail to Charing-cross.

*Saturday, August 6th*, 2 P.M.: Excursion to Folkestone. A certain number of members will leave Charing-cross Station by special train, provided free of cost by the South Eastern Railway Company, to witness the unveiling of the Harvey memorial statue. After the ceremony the Mayor and Corporation of Folkestone will entertain the visitors at a banquet in the Town Hall. 2 P.M.: Excursion to Hampton Court. Under the guidance of Dr. Langdon Down a party will visit Hampton Court Palace and Gardens, proceeding thence by river to Hampton Wick,

where they will be entertained by Dr. Down at a garden-party at his residence, Normansfield. The members can reach Hampton Court either by the road, the river, or the rail. A special train will leave Waterloo Station (South Western Railway) at 2 o'clock.

*Sunday, August 7th*, 1.30 P.M.: Excursion to Boxhill. A special train will leave Victoria Station (Brighton & South Coast Railway) for Boxhill. At Burford Lodge, close to the station, Sir Trevor Lawrence, Bart., M.P., will receive a party of the members of the Congress at luncheon. The train will return from Boxhill to London at 6 P.M.

*Monday, August 8th*, 11 A.M.: Visit to the Docks, under the guidance and hospitality of Sir George Chambers, chairman of the London, St. Katherine's, and Victoria Dock Company. A limited number of members will proceed to St. Katherine's Dock House on Tower Hill at 11 A.M., where the indigo and tobacco floors will be inspected, and in the adjoining London Dock, the ivory, drug, spice, and wool floors, and also the largest wine vault. From the Shadwell basin a steamboat will then take the party, for whom Sir George Chambers will provide luncheon on board, down the river to the Victoria Docks. Having passed through the Royal Victoria and Royal Albert Docks, the party will return by the river to Charing-cross pier.

WILLIAM MACCORMAC,
*Honorary Secretary-General.*

CASTRATION FOR DEMENTIA FROM MASTURBATION.—Dr. W. L. Folsom, in a letter to the *Michigan Medical News*, says that in 1843 Dr. Josiah Crosby, then at Laconia, N. H., and later at Manchester, N. H., with the assistance of Dr. Folsom and another medical student, and with the consent of the patient and his father, castrated a young man for approaching dementia from masturbation. The patient was twenty-two years of age, and was intelligent and educated. He had ceased to leave his house, or to mix in society, and did not wish to see any one. He had been medically treated by various physicians, but to no purpose. The operation completely cured and restored him to usefulness. He became afterward an active business man.

Dr. Folsom believes that this was the only treatment that could have saved the patient, and he believes that there are many just such cases throughout the land now who can be cured in no other way. Superintendents of insane asylums especially, should, by the consent of the man's friends, castrate hopeless cases of dementia from masturbation.

A CURIOUS CASE OF MALPRACTICE.—Dr. Caroline S. Pease, of Troy, N. Y., writes: "In June of the present year a patient presented herself at my office for examination, who gave the following history: Two years ago she was attended in her first labor by her family physician, a homœopath of good reputation. A laceration of the perineum was sustained, which was promptly operated on by the attendant. As the result of this, as he informed her, a partial union took place, but a secondary operation would be necessary so soon as her strength permitted. The usual subjective symptoms followed—constant backache, fulness low in the pelvis, etc.—and her general health became greatly impaired. After her labor no attempt at resumption of the marital relations was made, and dread, both of the surgeon's knife, and of the exposure incident to the secondary perineal operation, led to its postponement until a friend induced her to place her case in my hands, two years after the injury was sustained. Ocular inspection revealed a fairly good perineum, but a digital examination disclosed the fact that the anterior inferior portion of the cervix uteri had been included in the line of perineal union, and had firmly united with it. Two years' unremitting traction had drawn out a circular cord (which incision subsequently showed to be tubular) of the imprisoned uterine tissues, about three-fourths of an inch in length by one-third of an inch in diameter. This I afterward ligated and cut, at the patient's house, and was then enabled to restore the long-suffering organ to something like its pristine position, and to retain it there by an Albert Smith pessary."

PRESCRIBING THEIR OWN MEDICINES.—At a recent meeting of the Philadelphia Medico-Legal Society, the relation of physician and druggist was discussed at considerable length, and some interesting facts were given regarding the plan of the physician prescribing his own medicines. Dr. Peltz had tried this plan, and with great success.

A somewhat unique method was that described by others. The physician in this case employs a graduate in pharmacy, who calls at the close of his office hours for all the prescriptions. These he takes and compounds *secundum artem*, and delivers at the patients' residences, the physician keeping the prescriptions. This plan had worked well for several years.

REMOVAL OF RUPTURED UTERUS.—A correspondent of the *Boston Medical and Surgical Journal*, described an operation recently performed by Professor Braun at Vienna, which is certainly bold, and might be called unjustifiable.

A woman of thirty-five had been in labor thirty-six hours, and was nearly exhausted. Pains very feeble. She was delivered by forceps with some difficulty, when it was suddenly ascertained that the uterus was ruptured. The abdominal cavity was at once opened, and the uterus removed by the galvano-cautery, so as to make as little hemorrhage as possible. The division was made just above the cervix, which was left behind in the abdomen. There was not much hemorrhage from the operation. Carbolic spray and dressing were used. The woman died in about eighteen hours. The child could not be resuscitated. The cause of the rupture was not ascertained.

TINCTURA FERRI CHLORIDI.—Dr. H. Hagar recommends that tincture of chloride of iron be mixed with simple syrup and then with milk, this mixture not affecting the teeth nor the usual styptic taste being apparent.—*Druggists' Circular.*

THE OLEOMARGARINE BILL, which passed the New York Legislature, was vetoed by the governor.

AUSTIN FLINT, M.D., LL.D.—It is with a feeling of more than ordinary satisfaction that we announce the fact that Yale College, at her recent commencement, conferred upon Prof. Austin Flint the degree of LL.D.

AN EASY WAY TO ROLL BANDAGES.—A subscriber writes: "To the country practitioner, who has to make his own roller-bandages: bore a hole through each side of a cigar-box near the top; screw the box to something solid, bend a piece of wire to form a crank, run it through the holes in the box; wet the end of the bandage, lay it on the wire, and wind up. When done, make two or three reverse turns, and draw the wire out. Try it."

# BUFFALO LITHIA WATER

FOR BRIGHT'S DISEASE OF THE KIDNEYS,

AND FOR THE GOUTY OR URIC ACID DIATHESIS.

**DR. WILLIAM A. HAMMOND, OF NEW YORK,**

*Surgeon-General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.*

"I have for some time made use of the Buffalo Lithia Water in cases of affections of the NERVOUS SYSTEM, complicated with BRIGHT'S DISEASE OF THE KIDNEYS, or with a GOUTY DIATHESIS. THE RESULTS HAVE BEEN EMINENTLY SATISFACTORY. Lithia has for many years been a favorite remedy with me in like cases, but the BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION OF THE LITHIA SALTS, AND IS, MOREOVER, BETTER BORNE BY THE STOMACH. I also often prescribe it in those cases of CEREBRAL HYPERÆMIA, resulting from over mental work—in which the condition called NERVOUS DYSPEPSIA exists—AND GENERALLY WITH MARKED BENEFIT."

**DR. HUNTER McGUIRE, OF RICHMOND, VA.,**

*Professor Surgery, Medical College of Virginia; Vice-President of the International Medical Congress; Vice-President American Medical Association.*

"IN MY EXPERIENCE, THE BUFFALO LITHIA WATER IS VALUABLE IN A GREATER VARIETY OF DISEASES AND DISORDERS THAN ANY OTHER MINERAL WATER THAT I HAVE EVER EMPLOYED. As an ALKALINE DIURETIC IT IS INVALUABLE. IN URIC ACID GRAVEL, and, indeed, in diseases generally of the URIC ACID DIATHESIS, it will be found a remedy of EXTRAORDINARY POTENCY. I have prescribed it in cases of OLD RHEUMATIC GOUT, which has RESISTED THE ORDINARY REMEDIES, WITH WONDERFULLY GOOD RESULTS. I have myself suffered a great deal from this malady, AND HAVE DERIVED MORE BENEFIT FROM THIS WATER THAN FROM ANY OTHER REMEDY I HAVE USED."

**WATER, IN CASES OF SIX GALLONS, AT THE SPRINGS, $5.00.**

# JEFFERSON MEDICAL COLLEGE,

## PHILADELPHIA.

THE Fifty-seventh Session of the Jefferson Medical College will begin on Monday, October 3, 1881, and will continue until the end of the third week of March, 1882. Preliminary Lectures will be held from Monday, 12th of September.

**PROFESSORS:**

JOSEPH PANCOAST, M.D.,
General, Descriptive, and Surgical Anatomy (Emeritus).
S. D. GROSS, M.D., LL.D., D.C.L., Oxon., LL.D., Contab.,
Institutes and Practice of Surgery.
ELLERSLIE WALLACE, M.D.,
Obstetrics and Diseases of Women and Children.
J. M. DA COSTA, M.D.,
Practice of Medicine.

WM. H. PANCOAST, M.D.,
General, Descriptive, and Surgical Anatomy.
ROBERT E. ROGERS, M.D.,
Medical Chemistry and Toxicology.
ROBERTS BARTHOLOW, M.D., LL.D.,
Materia Medica and General Therapeutics.
HENRY C. CHAPMAN, M.D.,
Institutes of Medicine and Medical Jurisprudence.

The enlargement of the College, now in progress, will enable the Faculty to perfect the present system of *Practical Laboratory Instruction*, in all the Departments. Rooms are assigned in which each Professor, with his Demonstrators, will instruct the Class, in Sessions, in direct observation and hand-work in the Chemical, Pharmaceutical, Physiological, and Pathological Laboratories. Operative and Minor Surgery, and investigation of Gynæcological and Obstetric conditions on the *Cadaver* will be taught, as also Diagnosis of Disease on the living subject.

This course of Instruction is *free of charge, but obligatory upon* candidates for the Degree, except those who are Graduates of other Colleges.

A SPRING COURSE of Lectures is given, beginning early in April, and ending early in June. There is no additional charge for this Course to matriculates of the College, except a registration fee of five dollars; non-matriculates pay forty dollars, *thirty-five of which, however, are credited on the amount of fees paid for the ensuing Winter Course.*

CLINICAL INSTRUCTION is given *daily* at the HOSPITAL OF THE JEFFERSON MEDICAL COLLEGE, throughout the year, by Members of the Faculty, and by the Hospital Staff, which is constituted as follows:

**SURGEONS:**
JOHN H. BRINTON, M.D., S. W. GROSS, M.D.,
R. J. LEVIS, M.D.

**OPHTHALMIC SURGEON:**
PROF. WILLIAM THOMSOM, M.D.

**AURAL SURGEON:**
L. TURNBULL, M.D.

**PHYSICIANS:**
J. SOLIS-COHEN, M.D., JAMES C. WILSON, M.D.,
OLIVER P. REX, M.D., W. W. VANVALZAH, M.D.

**GYNÆCOLOGISTS:**
F. H. GETCHELL, M.D., J. EWING MEARS, M.D.

**PATHOLOGIST:**
MORRIS LONGSTETH, M.D.

**FEES:**

| | | | |
|---|---|---|---|
| Matriculation Fee (paid once) | $5.00 | Practical Anatomy | $10.00 |
| Ticket of each Professor (7) $20 | 140.00 | Graduation Fee | 30.00 |

Fees for a full course of Lectures to those who have attended two full courses at other (recognized) Colleges—the matriculation fee, and ..... $70 00
To Graduates of less than three years of such Colleges—the matriculation fee, and ..... 50 00

GRAND MEDAL | *Report of the Judges at the International Exposition, Philadelphia, 1876.* | AND DIPLOMA.

"NOVELTY, GREAT VALUE IN PHARMACY, UNEQUALLED PURITY AND SUPERIORITY OF MANUFACTURE"

# GELATUM VASELINE PETROLEI

**Awarded Silver Medal at Paris Exposition, 1878. Medal of Progress by American Institute, 1880.**

**Bronze Medal and Diploma Awarded by the American Institute for 1874.**

"Vaseline is an admirable preparation for many of the uses mentioned. As a base for ointments, it has given great satisfaction, while its freedom from rancidity or liability to become rancid gives it great advantage over many animal and vegetable fatty bodies. We deem it an article of great value, and deserving of special mention for the above purposes." Bronze Medal awarded.

Signed by { P. W. BEDFORD, ISADOR WALZ, } Chemists.

The attention of physicians, druggists and hospitals, is called to this article, and to the fact that it is favorably regarded and extensively used in the United States, on the Continent and in England, by the profession, and by pharmacists as a base for

## OINTMENTS, CERATES, &c.

As a dressing for *WOUNDS, CUTS, BRUISES, BURNS, SPRAINS, PILES, RHEUMATISM, SKIN DISEASES, CATARRH, SORES OR ERUPTIVE DISEASES,* and all contused and inflamed surfaces, it is not equalled by any known substance.

In the treatment of *COUGHS, COLDS, CROUP, DIPHTHERIA,* and of *THROAT* and *CHEST* complaints, the best results are obtained.

**One-Pound Cans. 75c. Five-Pound Cans, $2.00**

### Extract from Report of Dr. Galezowski, the distinguished French Oculist.

"Vaseline is the best pharmaceutical preparation in the making of ointments, as it is completely neutral and unchangeable. I saw it used for the first time in London by Dr. Lanson. I then procured the 'Vaseline' myself, and I have experimented with it for four months on over one thousand patients, and I must declare that the knowledge acquired by practice has surpassed my expectations by far. * * * * I have also prepared large quantities of eye ointments with 'Vaseline' and have employed them on numerous maladies with very great success, and I can affirm that 'Vaseline' is very precious in ocular therapeutics, and must replace all the ointments in use at the present time. * *

"In conclusion, on account of its unalterability and its great affinity for perfumes, I believe that 'Vaseline' merits the attention of the scientific and industrial world."

**DR. REUSCHE, of Hamburg *(translation)*, says:**

"In six cases of small-pox I have used Vaseline with eminent success—one a severe case of variola vera—a boy sixteen years old, not vaccinated.

"It developed the disease rapidly, and shortened considerably the duration of it—the time varying from seven to twenty days, the latter period for the most serious case only.

"While the application of Vaseline was regularly renewed, all inflammation and fever were kept off, and none of the patients, at any time, suffered any pain or great inconvenience, whereas, if neglected, the patient would become irritable and feverish.

"Applied internally, it removed the small-pox in the mouth and throat in a few days.

"A few scars remained in only one case, but the patient will outgrow these, as they are very slight."

**From the LONDON LANCET, Jan'y 5th, 1878:**

"We have before noticed this preparation of petroleum in terms of warm praise. It is of the consistency of butter, is perfectly free from odor, and does not become rancid. We have now before us several new preparations made from it, which *are so useful* as to call for remark. They are a *pomade* a *cold cream*, and a *camphor ice*, all of excellent quality. We have tried all of them with most satisfactory results, having found them greatly superior to the preparations in common use."

**Silver Medal and Diploma Awarded by the American Institute for 1875.**

"This article is one of great merit as a base for Cerates, Ointments, etc., and for Medicinal and Toilet uses, and is superior to the present bases used for Cerates, etc. It deserves the patronage of the profession, and shows maintained superiority." A Silver Medal awarded.

Signed by { NEWTON SQUIRES, Chemist. F. W. HUNT, R. R. PERCY, } M.D.

We manufacture the following Standard Ointments, according to the United States Pharmacopeia, using Vaseline as a base instead of lard;

# A MANUAL OF DISEASES OF THE THROAT AND NOSE

By FRANCKE H. BOSWORTH, A.M., M.D.,
*Lecturer on Diseases of the Throat in the Bellevue Hospital Med. College, &c. &c.*

**In one handsome octavo volume of 448 pages, bound in Muslin. Price, $3.25.**

**EXTRACT FROM AUTHOR'S PREFACE.**

I have embodied in the following pages the results of an experience, in dealing with throat affections, extending now over nearly ten years, and which has embraced the observation, treatment, and, in the large proportion of instances, the observed results of treatment, of something over eight thousand recorded cases. These have been partially in private practice, but mainly at the Bellevue Clinic for Diseases of the Throat.

In making these results public I have endeavored to confine myself to my own personal experience, recording, with candor and fidelity, both the method and measure of my success in those affections in which success has followed treatment, and, at the same time, and with the same candor, acknowledging the difficulties and disappointments which have attended the management of those diseases in the treatment of which I have failed of full success.

In describing special methods of treatment, I have endeavored to enter into full detail, preferring to err in this direction, rather than to fail of making myself clearly understood.

*Sent by mail, post-paid, on receipt of price.*

**WM. WOOD & CO., Publishers, 27 Great Jones Street, New York.**

*An annual advertiser in* THE MEDICAL RECORD *has a positive assurance that nearly half a million of his announcements are placed acceptably in th hands of nearly ten thousand actual paying subscribers, and probably twice that number of readers. Careful consideration of the prices for advertising in* THE MEDICAL RECORD, *and comparison with the cost by any other method, especially with journals which circulate only a few hundred copies, we think will convince you at once that it is economy to advertise in* THE MEDICAL RECORD.

**A PRACTICAL TREATISE ON THE**

# MEDICAL AND SURGICAL USES OF ELECTRICITY.

**INCLUDING LOCALIZED AND GENERAL FARADIZATION; LOCALIZED AND CENTRAL GALVANIZATION; ELECTROLYSIS AND GALVANO-CAUTERY.**

By GEO. M. BEARD, A.M., M.D., and A. D. ROCKWELL, A.M., M.D.

Third Edition. Revised by A. D. ROCKWELL, M.D.

**With nearly two hundred Illustrations. Price, bound in muslin, $5.50; in leather, $6.50.**

**EXTRACT OF PREFACE TO THE THIRD EDITION.**

In issuing a third edition of this work, I have endeavored to make such additions as seemed necessary, and, at the same time, avoid an increase in size. This has been accomplished by condensing wherever possible, and omitting portions here and there which have served their purpose, and are no longer of value. Two new chapters on the Sequelæ of Acute Diseases, and on Exophthalmic Goitre, respectively, have been inserted, while several pages in the discussion of Electro-diagnosis have been omitted, and the space occupied by later and more exact information. The chapters on Diseases of Women have been revised, and the clinical additions will be found interesting and suggestive, while in the discussion of Midwifery, the complication of Extra Uterine Pregnancy is fully considered.

**NOTICES OF THE PRESS.**

"This work has already established itself as a standard treatise. It is almost indispensable to the physician who needs a competent guide to direct his electro-therapeutic manipulations."—*New York Medical Record*, March 12, 1881.

"This Treatise has fairly maintained its position for ten years, as the standard American work on Medical Electricity."—*Medical and Surgical Reporter*, March, 1881.

"This book is too well known to the profession as the largest and most perfect work on Electricity to require any recommendation from us."—*Buffalo Medical and Surgical Journal.*

"The work is above criticism. It forms a whole cyclopædia of every principle and fact pertaining to Electricity.—*Chicago Medical Journal and Examiner.*

"The most satisfactory work to the general practitioner with which we are acquainted."—*Louisville Medical News.*

"This work has been before the profession just ten years, with increasing popularity and usefulness. It now becomes the most complete book upon the subject published."—*St. Louis Courier of Medicine, etc.*

"All that we have said in commendation of previous editions of this well-known work, can be said of this, and even more. No one, interested in the many medical and surgical applications of electricity, can do without this volume. Dr. Rockwell is to be congratulated upon having reduced the number of pages in this edition, while, at the same time, increasing its value."—*American Practitioner*, May, 1881.

"This work is so well known by its former editions, as to require but little more than the mention of it on the occasion of the appearance of the Third Edition. It is the most full and complete work issued from the American Press."—*Pacific Medical and Surgical Journal*, May, 1881.

*Sent by mail, post-paid, on receipt of price.*

**WM. WOOD & CO., Publishers, 27 Great Jones Street, New York.**

# Original Lectures.

## THE PHYSIOLOGY OF THE PHENOMENA OF TRANCE.*

By C. L. DANA, A.M., M.D.,

PROFESSOR OF PHYSIOLOGY IN THE WOMAN'S MEDICAL COLLEGE OF THE NEW YORK INFIRMARY. PHYSICIAN TO THE CLASS OF NERVOUS DISEASES, NORTHEASTERN DISPENSARY.

The subject of what is popularly known as mesmerism has been lately exciting considerable attention, and it seems to possess enough of physiological interest to justify my bringing it to your notice in the present course. The phenomena, under the various names of animal magnetism, hypnotism, trance, etc., have long been known. They were first scientifically studied by the French Academy, nearly a hundred years ago, and then again by the same body in the early part of this century. Mr. Braid, an English surgeon, investigated the subject in 1843, and made a more thorough and scientific examination of it than ever before. His results were not received by scientists or medical men, however. In the past decade, and especially in the past two years, the phenomena in question have received more careful attention from scientific men than at any time previously. At present, investigations are going on in this country, in England, France, and Germany, and now the subject has been put upon a sufficiently scientific basis to allow of a physician's studying it and believing in its reality, without losing caste.

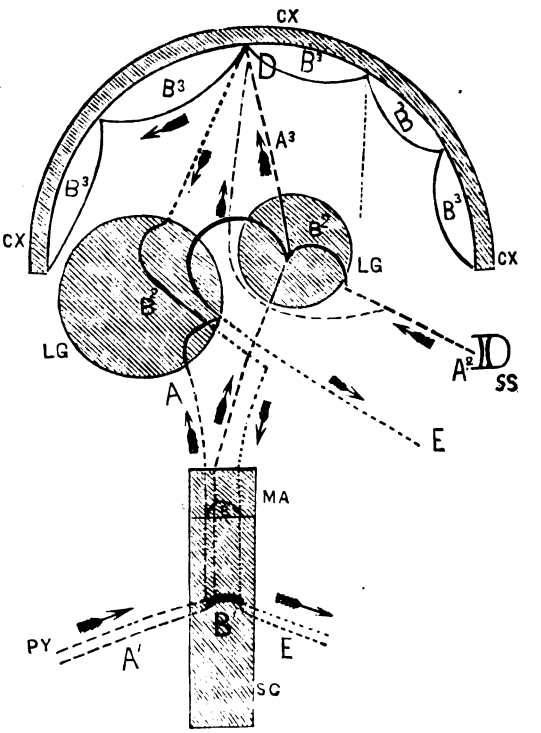
There are certain physiological facts which I wish to refer to, before showing trance phenomena in the subjects that I have here.

There exists in each of us what the philosopher Locke well described as a "power to begin or forbear, continue or end the several actions of our minds and motions of our bodies, barely by a thought or preference of the mind." This power is called the Will. It is not thought by modern psychologists, or even by all of the older schools, to be a separate and distinct force enthroned within us. Exactly what it is, however, is a question that we need not enter upon now. We do know that every man can check, regulate, or set in action, such muscular movements, or such trains of thought, as he wishes. You can understand that if this power were taken from us, it would materially limit our physical and mental being. We should be very much like machines, acting only, or chiefly, under certain stimuli applied from without. Our actions would then be essentially reflex in character. The reflexes would differ much in complexity, however, and they might be roughly divided into three classes:

I. The first embraces the simple reflex actions. I have told you what they are, and that they are processes which belong pre-eminently to the spinal cord and medulla.

II. The second class embraces higher centres and more complex activities.

You know that human beings all possess more or less of certain dexterities, such as riding, walking, the playing on musical instruments, etc. There are a few of these, such as suckling, which are possessed even at the time of birth. But the most are acquired by practice. Whatever their kind, we go through the various complicated movements pertaining to them, for the most part unconsciously. Thus, a person can walk, or dance, or play, and be entirely unconscious of any voluntary effort being expended. Now, we characterize these acquired and these inborn dexterities as automatic; and such, indeed, they are, using the term automatic in perhaps a rather loose sense. They are machine-like in character. Once being started they go on as a clock does when it is wound up. And we suppose that the particular place where this machinery is located is in the lower ganglia and hinder part of the brain, probably in the corpora striata and cerebellum. The cells and connecting fibres in these ganglia have become arranged into definite groups, each corresponding with and governing certain classes of muscular movements.



Diagrammatic representation of reflexes in trance: *sc*, *m*, spinal cord and medulla; *ss*, a special sense; *lg*, lower ganglia; *py*, peripheral surface of body; *cx*, cortex; $B^1$, $B^2$, $B^3$, commissural and associating fibres; = = =, afferent fibres; ....., efferent fibres. The curved lines $B^1$, $B^2$, $B^3$ represent the commissural fibres in the three different kinds of reflexes.

In ordinary (mesmeric) trance, afferent impulses pass generally to the cortex (*e. g.*, D), there to excite dominant ideas. In somnambulistic trance, the afferent impulses, starting from *py*, *ss*, or D, pass probably to the lower ganglia and excite the automatic machinery there. In trance-coma nearly all reflexes, except those of the medulla, are abolished.

All that is needed to set or keep these groups at work is the proper stimulus or successive stimuli; they then go on discharging efferent impulses, and producing the definite motor results.

We have an example of this in the inception and continuance of an ordinary walk, or in playing a well-known piece of music. It is a case like that of setting a machine going by the turning of a key. The cerebellum we may assume to be the machine, which has acquired certain powers of sending out co-ordinated impulses. It is generally set in motion at first by conscious impulses from the higher brain-centres, themselves roused by the visual sense. But

* Lecture delivered in course at the Woman's Medical College.

after a time it may also be stimulated by afferent impulses that do not rise to consciousness, but go directly to that part of the brain alone.

You can see by the diagram (p. 85) the course of the incoming and outgoing impulses in the case of habitual dexterous movements, and how the process may be called a reflex one. When the impulses go to and fro without exciting consciousness, we suppose that they do not pass up to the cortex at all, and that only the lower ganglia are active. The reflexes are genuine, but more complicated than those of the spinal cord. We may class them as reflexes of the second order, or of the middle projection system.

I have said that in unconscious and automatic acts the brain-cortex is not active. I will warn you, however, that this is rather an inference than a fact.

III. But we have still a third and higher system, in which there may be reflexes. Thus, a person sees an object which excites in him emotions of fear, or hears a suggestion which excites an idea, and which in turn excites the desire to cry out. In the former case we trace the afferent impulse along the optic nerves to the part of the brain concerned in sensation and ideation, and that process of linking the two, which is called perception. From these higher centres efferent impulses start down to the facial or other muscles, and the expression of fear is seen upon the countenance.

In the second case the process is a similar one. The afferent impulses give rise to a sensation which links itself to the previously impressed sensations (now become ideas), and a train of thought is aroused. After travelling through this ill-understood nexus between the afferent and efferent impulses, the latter excite the organs of speech.

In these various processes there is normally almost always a consciousness of the changes that are going on. The changes include sensation, perception, ideation, and what is known as volition.

Again, here, as in the second class of reflexes, the afferent impulse need not be constantly acting. It may start the machinery of ideation, which will then continue to act and send out more or less of expressive efferent impulses. Thus, a single frightful sight may give rise to prolonged feelings of terror, which in turn are expressed through various efferent channels for a long while.

We may represent this as a reflex diagramatically, as you see here.

Now, in the *first class* of reflexes consciousness and volition never enter.

In the *second class*, consciousness and volition may attend the inception of the process, but not necessarily, or generally, the rest of it.

In the *third class*, consciousness is always, in normal conditions, present, and acts of volition generally modify the play of afferent and efferent impulses.

The reflex character of the afferent and efferent impulses in the second and third class is, normally, obscured by these acts of volition. We shall see, however, that in the phenomena of trance, volition is taken away entirely, and if there is any consciousness, it is dim, and, so to speak, abnormal; so that the three reflexes described underlie the whole of the subject's mentality.

There is another physiological point which I wish to bring out.

The nervous system is a mechanism for liberating, and at the same time co-ordinating and regulating the various special energies or functions of the body. That it may do this more perfectly, and perhaps for other reasons, the brain, with its highly complicated powers, is developed. Now, this nervous system seems capable of bringing into activity (or making kinetic) a certain amount of energy, which is normally distributed throughout the nervous system, more or less equally. Thus, it can at once move muscles, and can keep all the special senses and the mind itself moderatively active. We can walk about, can see, hear, feel, and think at about the same moment. But it cannot make any of the special functions of the body particularly active, it cannot liberate nervous energy largely in one particular direction without the other parts suffering. While watching intently, we cannot feel, or taste, or hear with any great degree of perfection. While reflecting deeply, the special senses are somewhat dulled. If the nervous system is busy in sending out powerful or delicately adjusted motor impulses, its other duties are somewhat neglected. I am only expressing, in physiological language, the very commonplace fact that we can only do one thing well at a time. And furthermore, that we have the power, by exercise of our will, of directing the nervous energies almost exclusively in one or two directions. That is to say, we have the power of concentrating our attention.

Now, this mobility, so to speak, of our nervous or mental energies, this capacity of being turned into one channel and acting very powerfully there, is most conspicuously brought out in the phenomena of trance. It is a leading characteristic of the state, as was first shown by Dr. G. M. Beard.

I think that if these preliminary explanations are obscure, an exhibition of the phenomena in the patients here will soon make my meaning clear.

This young man is a very susceptible case, and I can put him into the trance state in various ways. The method most approved by professional mesmerists is to have the person experimented on close the eyes. You then put your hand upon the forehead and make gentle passes along it. At the same time you talk to the patient in a confident tone, assuring him that, in a few moments, he will not be able to open his eyes. After five or six minutes of such manipulation, you tell him positively that after you have counted a certain number he cannot open his eyes. If the patient is susceptible, it will be found, as you see in this case, that he cannot raise the lids, no matter how hard he tries.

The patient is now in a trance, and we can manipulate him as we wish.

We will begin with the simplest exhibitions of the state. The subject sits here with eyes closed and head drooping. He looks very much like a person who is in a deep sleep. His hands drop when I raise them; his pupils react; if I irritate his skin quite sharply, he draws his hand away. But his condition is really very different from that of sleep, as we shall soon discover.

In the *first place*, you will see that the simple spinal reflexes are much less easily brought out than in sleep. In the lighter stages of sleep these simple reflexes are generally somewhat exalted. They are hardly ever so dulled as is found in trance subjects.

Then, again, if any of you should try to wake him up by the ordinary methods, you would be unsuccessful. You see that I can push him, shake him, call to him to wake up, and use all the means generally employed, even that of pinching and pricking, yet he does not rouse at all. On the other hand, if I simply snap my finger and call "All right," he is awake in an instant. Snapping the fingers is not

the only way by which these trance subjects can be roused, however. They respond, ordinarily, when not too deeply entranced, to whatever form of awakening stimulus they have been accustomed to. You might fire a gun at the side of a hypnotized subject without disturbing him. Yet a breath of air upon his face would dehypnotize him, if that method had been usually employed. Here, then, is a *second difference* between the sleeping and the trance state.

A third and less notable characteristic is that, despite his having been apparently in profound unconsciousness, the moment he is aroused, he is, as you can see, perfectly wide awake, having none of the drowsiness that attends the awakening from ordinary deep sleep.

I will now hypnotize him again, and show a *fourth* and much more remarkable peculiarity of his condition. The subject sits here with eyes closed and apparently insensible to external surroundings. But his mind is in a most curiously abnormal condition. His will, or capacity for spontaneous action, in the first place, is entirely suspended. If left alone he would sit here for hours. The crash of worlds would not arouse him, unless that had been the customary dehypnotizing agent. He would finally pass into a genuine sleep, from which he would after a time awake. But there is something more than a suspension of his volition here. My own will has in a manner taken the place of his. Whatever I will or suggest to him to do, he does with as much certainty as if his mind were my own. But, still further, in whatever direction I turn his mind, in that direction his whole mental energies are concentrated. He not only responds to every suggestion or order of mine, but his whole mental powers are fixed upon that suggestion or command.

Thus I tell him now that he can open his eyes. He is able to do so, though he could not before. I hold out my hand and tell him to strike out hard at it, but that he cannot hit it. You see that he strikes frantically at me, but misses every time. I tell him that his right arm is getting rigid. His whole mind concentrates itself on this idea that it is rigid, and you see how perfectly stiff it has become. I stroke one side of his body and assure him that it will be perfectly numb and insensible. I now pinch it and prick it as violently as possible, but he makes no response. I might cut or burn it with the same result. Here the perverted mental energies act in some new way. Afferent impulses are prevented from rising into consciousness, and no pain is felt. The mechanism of this is unknown. It is a phenomenon of which we hardly have an analogue in the normal state. It is hard to understand how any concentration of the mental powers can directly abolish sensation. We know, however, that the brain possesses certain inhibitory powers which help to control and regulate the nervous system. We must suppose that some of these inhibitory activities are called out in the trance state.

There are still other phenomena:

I tell him that he has a frightful pain in his stomach, and you see by his expression of agony that he surely thinks he has a colic. I tell him that he is getting stiff all over, and he straightens up like a frog under strychnine. I place him with heels upon one chair and occiput on another, and you see that he holds himself there perfectly well, even when some weight is on his abdomen. It is doubtful if he has the physical power to do this when in his normal condition.

In various ways I can also pervert or exalt his special senses. Thus, I have some colored worsteds here. I tell him that I want him to sort them out, putting like shades with like. At the same time I impress on him the fact that he will surely mix the colors. You can see what mistakes he is making. It so happens that in this case he is making much such mistakes as a color-blind person would; that is, he is mixing the drabs, browns, and greens together. These subjects are not generally color-blind, however, in the same way that persons having congenital color-blindness are: the latter mix only certain colors. But these patients mix any, without special rule.

By tests with large and small types, we can sometimes show that the acuity of vision is increased. And by telling this patient that he was perfectly blind, he would grope around the room with every evidence of having no sense of vision whatever. More delicate tests would prove that sight was greatly dimmed, or nearly abolished. Among a very few exceptionally sensitive trance patients there exists apparently the power of exalting the vision in a most extraordinary way. Not long ago, Dr. G. M. Beard, Dr. W. J. Morton, and myself, tested one of these cases. The subject, a woman of thirty-five, was hypnotized by her husband, who was the only other person in the room besides the patient and the physicians. Her eyes were closed and bandaged with four handkerchiefs and a strap. The husband's eyes were also bandaged, and he was placed at the other end of the room. The woman then read a number of cards, that were handed her, told colors, etc. A similar case has been experimented upon by Dr. E. S. Bates, of this city. I do not dwell upon these phenomena, however, because they are of the kind that few can believe in until they have seen them themselves.

As we can in this subject pervert, exalt, or abolish the sense of vision, so we can the other senses. You see how eagerly he snuffs up this mixture and calls it cologne. It is really valerian. On the other hand, when I present this bottle which I assure him is disgusting, he turns away his head, although it is really cologne. In the same way I make him smack his lips over a mouthful of quinine, and spit out an excellent quality of sugar. What is still more curious, I can make him appreciate the bitterness of quinine on one side of his tongue, while he thinks it sugar when I place it on the other.

There is another set of phenomena connected with the higher nervous centres which I now wish to show you. They illustrate the same fact that the patient's mental equilibrium is disturbed, and that by my suggestions I can turn all the energies of his mind in whatever direction I choose. I stand this patient beside me and tell him to look at the beautiful angels that are hovering about in the upper corner of the room. You see how rapt his gaze has become, and how he wears an expression of ecstasy which no actor could assume so perfectly. If I tell him that they are gone and that a horrible fiend is perched up there, the change in his features shows how completely his imagination responds to my suggestion. And you notice that in this, as in the other phenomena, it is not alone that the mind is directed entirely on one subject, but it is concentrated there with an intensity which no normal volition or external stimulus could produce. This boy now sees some monstrous fiend; he sees nothing else, and it is more real and appalling than any actual monster could be. If I should tell him that it is coming at him and has struck him dead he would fall down al-

most lifeless. The experiment is a little dangerous, so I tell him that the object is gone, snap my fingers and rouse him from the trance. He looks around as you see, and wonders what he has been doing.

These patients sometimes have a vague consciousness of what has been occurring, but oftener remember nothing at all.

I take the other young man now, and having hypnotized him, I tell him that he is a temperance orator; that he has an audience of depraved and, perhaps, irreclaimable drunkards before him, and beg him to talk to them. He thinks now that these are really the conditions, and he talks to you with a force and earnestness which I am sure is not at all called for. If I press on the back of his neck, over the seventh cervical vertebra, you see that he stops speaking, though his lips move. He is aphonic. If I press upon the side of his face, just below the ear, he begins to speak again.

These are most curious reflex effects, which it is not very easy to explain. It is probably a fact that in all trance-speakers there is some point upon irritation of which aphonia may be produced. And there are other points upon excitation of which the speech will be resumed. The special point differs probably according to the training of the subject or the suggestions made to him. Sometimes waving the hand before the face stops the speech, while waving in the contrary direction sets it going again.

It may be that these phenomena, though apparently very striking, are, after all, due chiefly to suggestion. Experiments seem to show that we can by suggestion exalt the imagination and emotional faculties much more than the intellectual powers. I can make this person imagine anything, and that with the greatest intensity; and I can make him feel any emotion, from the highest ecstasy to the most harrowing remorse. But any complex intellectual act I cannot incite him to, and even in performing simple intellectual feats he will not show much greater quickness. Thus, I can make him do simple arithmetical problems with more readiness than in his normal state. But the mathematical powers cannot be very much exalted. He cannot follow out a complex series of actions unless they belong to a class with which he is familiar and has habitually performed.

I can tell him that this stick here is money and that he must steal it and run. He will do so, and will run until he drops, but will show no further intelligence. I could tell him that my friend Dr. F. here is a murderer who has taken away thousands of lives, and ought to be killed himself. If I should give him a pistol and point out the man for him to shoot, he would do as I directed, and murder a most promising young physician; but his intelligence and his actions would end there.

In fact, as you have now seen, these subjects, when hypnotized, are reduced to the condition of machines which go when the proper impulse is given, and only then.

You can now see, also, the application of the facts regarding the different reflexes of the nervous system which I have described to you at first. Persons in trance are governed in their actions by these reflexes alone. The "power to begin or forbear" is entirely lost. Certain suggestions may arouse a tolerably long or complicated series of familiar physical or mental acts. But the suggestion is needed first, therefore the action is reflex. As you see, also, it is not the lowest and simplest of the reflexes, that is, those of the spinal cord, which are especially affected, but rather the higher ones that are brought out in acquired automatic movements, and, still more frequently, it is those which involve the activity of the cortical areas.

You must not think, however, that the mind is always intensely concentrated in one direction or another. A concentration of the attention seems to be necessary at the beginning, in order to induce the state in ordinary mesmeric trance, and Preyer has brought forward the improbable theory that such concentration produces fatigue-products which are the causes of the trance state. There is mental concentration in most of the phenomena of the different forms of trance, but it does not seem to underlie them all. And, of course, our saying that the mental energies are thrown powerfully in this or that direction is not a physiological, but a psychological explanation. We cannot yet, however, go any deeper. All the hypotheses in regard to peculiar states of the circulation, nutrition, etc., are as yet vague, unsubstantiated and useless. The concentration theory as announced and elucidated by Dr. Beard gives us a clearer understanding, at least, of the phenomena.

The suspension of spontaneity or volition, and the uniform response to outside or (as in somnambulism) inside suggestions, is the side of the subject particularly dwelt upon by Dr. W. A. Hammond, and on account of this perfect *en rapport* of subjects, he has called the condition syggignostic (συγγιγνωσκω, to agree with). It is better, however, to apply a name which conveys no theory.

It may have struck you that some of the phenomena which I have shown you resemble very much those of ordinary absent-mindedness. Ordinary absent-mindedness differs from trance chiefly in degree. In the matter of the responsiveness to outside suggestion and the suspension of the will the difference between hypnotism and absent-mindedness is most apparent.

The per cent. of persons who can be put into the trance state, as these young men are, is not known, because there have not yet been enough experiments made with all classes of people. Among German students the per cent. is said to be about one in twelve. Professional mesmerists in America say that they find one in six or eight of their audience susceptible. C. Richet says that every woman and almost every man is susceptible; but such a statement is hypothetical and unscientific.

Dr. G. M. Beard, who, more than any other physician in this country, has added to our knowledge of this subject, considers the various conditions known as catalepsy, ecstasy, katatonia, double-consciousness to be forms of trance. In some cases, it is probable that the special disease is not a form of trance but that trance is one of the symptoms of the morbid condition.

If we collect all the different conditions in man and other animals which seem to be varieties of trance, we can trace a gradual change from absent-mindedness and slight trancoidal states to well-marked trance of the kind I have shown you here, and from these to the still more strongly marked conditions of catalepsy, katatonia, and double-consciousness. There will appear to be no sharply drawn line between the normal and abnormal state. It will be evident, however, on studying individual cases of mesmeric trance, that there is in them a sharply drawn line between the trance and the normal condition. A person is either in a trance or he is not. He may be in it more or less deeply. When the latter is the case other parts of the brain work and modify the action of that particular part which is most exalted. The special exaltation is often not so complete that other thoughts, feelings, or muscular movements than the dominant ones, do not creep in.

As to the genuineness of the condition in question I have nothing to say here, as this is not the place to test it. Most of the phenomena which I have shown you might, perhaps, be simulated. You will take my word that they are not. The reality of the condition known as trance is as fully established as that of insanity. It is not so easy to give a scientific demonstration that any individual case is not shamming. Still, sometimes it will be possible to do this by means of what are known as the equilibrium-tests, the tests for muscular hyperexcitability, the eye-test, etc.

The practical bearing of this newly acquired knowledge of trance is not a subject on which I can enter now.

As regards the relation of the phenomena to physiology, it is too early to say what light they can throw on it. The facts of trance themselves, however, form a contribution to physiology or psychophysiology of extraordinary interest. I have shown you only some of the simpler phenomena of the condition, but you will admit that they reveal capacities of our nervous system which a study of it, in its normal condition, would never lead us to suspect. Robbing the mind, as it does, of its spontaneity, it becomes a simpler thing to study, and no doubt some additional light may be gained regarding its workings, especially in regard to the reception of outside impressions, the acquirement of experience, and the laws of association. The experiment that I showed you in which vertigo was abolished, upsets a current theory in regard to the functions of the semicircular canals in the preservation of the equilibrium.

In conclusion, what I have said may be summarized somewhat as follows:

*Mesmeric* trance is an abnormal condition of the nervous system characterized by the following phenomena:

1. Consciousness is perverted or suspended.
2. Volition is suspended.
3. Suggestions from the operator take the place of the will. The subjects are automatic; their actions reflex.
4. There is generally an intense concentration of the mental powers in one direction, with more or less consequent suspension in other directions.
5. Or there may be simply a suspension or inhibition of certain special energies, not due to any concentration elsewhere.
6. With regard to trance in general, assuming it to include the conditions mesmeric trance, somnambulism, double consciousness, catalepsy, katatonia, etc., we may add this:

*a.* The four especial characteristics of mesmeric trance: loss of spontaneity, concentration, inhibition or suspension, syggignosticism, do not always appear together or with equal prominence in other forms of trance. We may, therefore, have trancoidal states, and conditions shading into trance or into which trance enters. Mesmeric trance itself, however, is a sharply defined condition.

*b.* In all trance states inhibition or suspension of function is a more uniform characteristic than concentration. It is impossible to explain all the suspensions of function (as Beard does) by concentration.

If one wished to formulate a theory of trance, he might say: *In trance states the special co-ordinating agencies of the nervous system, will and consciousness, are put in abeyance. The remaining nervous energies are left in an unstable equilibrium, and may be concentrated, inhibited, perverted, etc., in various ways and with the production of various phenomena of trance.*

## CHRONIC CATARRHAL PYELITIS.

A Lecture Delivered in the Woman's Medical College, Chicago.

By ISAAC N. DANFORTH, M.D.,

PROFESSOR OF PATHOLOGY.

Ladies: I invite your attention this afternoon to the subject of chronic catarrhal pyelitis—a form of disease which is not very uncommon, but which is rarely recognized in its earlier stages. I am anxious that you should thoroughly understand this disease, because it is vastly important that it be diagnosticated while it is yet curable, for, if it is not, serious results are sure to follow. By catarrhal pyelitis I mean a catarrhal inflammation of the mucous membrane of that portion of the kidney which is known as the "pelvis," and it is important for you to understand that the pelvis is a structure quite distinct physiologically and pathologically from the kidney itself. It is a dense, membranous sac, lined by mucous membrane, and implanted upon the kidney proper. It serves only a mechanical purpose; it is, in fact, simply a part of that system of conducting-tubes which are attached to the kidney proper, and are mechanical adjuncts thereof. So, when you study the diseases of the *pelvis* of the kidney, you do not study the diseases of the kidney proper. It is, of course, true that a morbid process commencing in the pelvis may extend to the true renal tissue, just as a morbid process starting in the bronchial tubes may ultimately involve the true pulmonary tissue; but experience teaches us that the pelvis may be for a long time in a diseased condition without involving the renal tissue, and furthermore, that the morbid process is rather more likely to travel downward than upward; that the ureter, bladder, and urethra are more likely to be implicated than the tubuli uriniferi. The subject naturally divides itself into its morbid anatomy, its symptoms, its causes, its prognosis, and its treatment.

The morbid anatomy of catarrhal pyelitis is very simple and very easily described; and, I may add, is quite seldom studied, since patients never die of this disease alone, and when death is caused by some intercurrent disease, the attention is fixed upon the lesion it occasions. But, if catarrhal pyelitis be present, you will find the pelvic mucous membrane reddened and congested, sometimes quite intensely, sometimes only moderately. Here and there, more especially in the infundibula, you will find enlarged and tortuous groups of vessels; you will also find a considerable quantity of thick, glairy mucus—sometimes as much as a fluid drachm—and it will be mixed with a quantity of fine, gritty deposit, which consists of the precipitated urinary salts. It would seem that this abnormal mucus acts as a sort of filter, so that the saline constituents of the urine are strained off during the transit of the urine through the pelvis. And this brief description comprises the morbid anatomy of catarrhal pyelitis; it is so simple, and presents such feeble indications of abnormality, that many cases are passed by as healthy by pathological anatomists of limited experience.

The symptoms of this disease are not very pronounced; it may exist for months or even years and not be recognized—that is, if it maintains its simple catarrhal form. The patient is usually called upon to urinate a little oftener than usual, but the quantity of urine is not at all, or, at least, very slightly increased; the unpractised observer will scarcely notice any change in the appearance of the urine.

There will be a slight, or possibly, somewhat severe pain in the back over the region of the affected kidney. This pain will be quite constant, and will be increased by fatigue, violent exercise, intemperance, and, in fact, by almost any form of wearying excess. These lumbar pains are likely to be taken for rheumatism, and I may add that the treatment adopted for rheumatism is more than likely to aggravate the renal trouble. There will scarcely ever be tenderness over the kidney, and there will be no constitutional symptoms which can be referred to the kidney as their efficient cause. But the diagnosis can usually be established absolutely by an examination of the urine. In this, as in all other cases, the microscopic and chemical study of the urine is almost certain to reveal what is going on in the urinary organs.

Request the patient to bring you a four-ounce bottle of the morning urine; let it stand six or eight hours, and then proceed to study the sediment which covers the bottom of the bottle. But, in the first place, let me call your attention to what I may term the pre-microscopic stage of this examination and the lesson it teaches. You will, of course, use a pipette for the purpose of lifting a drop or two of the precipitate, that it may be placed upon a glass slip for microscopic examination. Now, when you raise the pipette with its upper end tightly closed by the finger, you will observe that a long string of clear, glairy, tenacious mucus will follow, as though it was attached to the pipette; it really is connected with the mucus which has risen up into the pipette, and is drawn up by this. This sign, when present, establishes this fact—that you have catarrhal inflammation of *something;* of course, it does not indicate its location, but it does establish its type. If the deposit consisted of pus instead of mucus, it would "break off short," so to speak; that is, the long string of sticky mucus would not cling to the end of the pipette. Of course, I need hardly tell the members of this class that the distinction I attempt to draw between catarrhal and suppurative inflammation is arbitrary and theoretical rather than natural and real, because in our studies in pathology we have long ago learned that we cannot exactly say where mucus-formation ends and pus-formation begins; that the two *apparent* processes are really but steps in one process. Nevertheless, there is a clinical and therapeutical—and, indeed, I may add a prognostic—advantage in maintaining this arbitrary distinction, as you will learn when I come to speak of suppurative pyelitis.

Now, we must proceed to the microscopical examination of the precipitate, and if the case be one of catarrhal pyelitis we shall have that fact clearly revealed by the presence of the following microscopic objects: 1. Mucous corpuscles, probably in great numbers, and varying considerably in size. 2. Epithelial cells from the pelvis of the kidney, both singly and in patches or flakes. These cells will be recognized at once by the fact that they are much smaller than those which line the bladder, although they resemble them as regards form and type. You will generally find large patches of them still adherent by their borders, and you will also find large numbers floating about which have become separated. 3. There will almost always be present, here and there, a short cylindrical aggregation of cells, derived from the papillary extremities of the tubuli recti, that is, that portion of the papilla which projects downward into the pelvis, and therefore becomes more or less subject to the pathological conditions affecting the pelvis. When these three microscopical objects are present in any considerable numbers and with anything like permanency, you may consider the diagnosis of catarrhal pyelitis as absolutely established. Of course, other objects will be seen, as urinary salts, cystic epithelium, etc., but they have no special diagnostic relation to pyelitis.

Unless the affection has proceeded beyond the catarrhal stage, the urine will not contain albumen, but it will contain a large excess of mucus, which fact will be proven by the clear, but exceedingly tenacious character of the sediment, and the appropriate chemical test for mucus, namely, acetic acid or alcohol, either of which causes coagulation of the mucus, and its precipitation in a white, semi-opaque mass. The causes of catarrhal pyelitis are about as numerous as the cases. Persons who are habitually and rapidly climbing stairs, as hotel-porters and letter-carriers; persons who stand a great deal in constrained positions, as railway postal clerks; persons who travel much or very constantly by rail, as conductors and express messengers, are peculiarly liable to this disease. Severe muscular exertion which involves the muscles of the back and abdomen and of the lower extremities may be mentioned as an efficient cause. So also oxaluria and phosphuria, when excessive and permanent, are liable to bring on pyelitis, probably on account of the irritating character of the crystals precipitated in the pelvis.

The prognosis of catarrhal pyelitis is generally favorable; nevertheless, it is by no means an easy or rapid disease to cure. Nor is it free from danger as regards its ultimate consequences, especially if it be neglected for any considerable length of time by the patient.

Every case of uncomplicated catarrhal pyelitis will be followed by one of these three results:

*a.* Recovery after a prolonged course of treatment. This result ought always to be reached in young or middle-aged patients of good habits, if they are free from any hereditary constitutional vice or weakness, and if they will submit to the proper treatment and regimen for a sufficient length of time.

*b.* A second group of cases will pass inevitably into the suppurative form. Patients beyond middle age or of intemperate habits, patients who are compelled to labor hard and constantly for their daily bread, patients who are heirs to some form of transmissible disease, are liable to suffer the misfortune of having a simple catarrhal pyelitis degenerate into the more formidable suppurative type, with all its attendant and irremediable evils.

Still another, although comparatively inconsiderable group of cases, will pass along, and become true Bright's disease, and this is especially liable to happen to habitually intemperate patients. At the same time, it is an inexplicable fact that pyelitis may exist for a very long time without implicating the tubular structure of the kidney. Suppurative disease with sacculated kidney is much more likely to follow than Bright's disease. But now and then a case occurs in which, despite all treatment, the inflammation will slowly travel up the tubuli, until the critical portion is reached, and then, of course, we have a true case of Bright's disease in addition to the pelvic lesion. As I have considerable to say concerning the treatment of pyelitis and the early stages of Bright's disease, I will make it the subject of my next lecture.

## A CASE OF
## COMPLETE INVERSION OF THE UTERUS
### Occurring Immediately after the Second Stage of Parturition.

By P. H. REICHE, M.D.,
WAVERLY, BALTIMORE CO., MARYLAND.

(Reported to Baltimore Academy of Medicine.)

I know of no emergency, nor can I conceive of any case in obstetrical practice that will cause more mental perplexity and worry to the accoucheur, and at the same time is more hazardous to the lying-in woman, than complete inversion of the uterus, following close upon the delivery of the child. This fearful accident is happily of very rare occurrence, and it is perhaps owing to its infrequency that the contributing causes carry with them some suspicion of bad management; yet, as the report of my case will show, it is at least sometimes the result of conditions over which the accoucheur, however skilful, can have no control. In consulting different authors in regard to inversion of the uterus, I find that this accident is almost always considered as a consequence of parturition, but the causes generally assigned by them as operating to produce it are so vague and undefined, that one would almost doubt the possibility of its spontaneous occurrence. In this case, however, it will be shown that there was no mechanical or exciting cause to produce it, that it was a purely spontaneous inversion, and that the power to be inverted was inherent in the uterus, being the result (as Barnes, in his "Obstetrical Operations," has suggested) of paralysis of the placental site, the existence of which was clearly made out at the time of its occurrence and the continuance of which was noticed for several days subsequent to its reduction.

Before entering upon a detailed report of this case, it is my desire to call the attention of the Academy to the previous history of this lady, which is indeed as exceptional and rare as the case now under consideration. She has had three consecutive labors at full-term, all with breech-presentations, besides one miscarriage of about two months, each one of which had its peculiar complications. She is now about twenty-eight years of age, rather below the medium height, of a slight form but healthy appearance. Was married January 13, 1875. Her first confinement, from the usual computation, was expected about the 20th of March, 1876. During the above period she enjoyed exceptionably good health. On that date she had quite a profuse hemorrhage from the uterus, without the least pain. When I arrived I made a vaginal examination, but could discover nothing to indicate a near approach to labor, the hemorrhage had also ceased, I therefore did nothing, but ordered absolute rest. In a day or two she was again on her feet attending to her household affairs, which she continued to do for about two weeks longer. During all this time she was not made conscious of any movements of the fœtus.

I was again called on April 3d. I found that strong contractions and severe labor-pains had set in; diagnosed breech-presentation and death of the fœtus. Her labor lasted about twelve hours. The child, a little larger than the ordinary size, yet well formed, was born without much assistance on my part, and the placenta followed the expulsion of the head immediately. Exfoliation of the outer layer of the skin was visible all over its body. The placenta was very dark, and looked as though it had been detached from the uterus for some time, yet there was no disagreeable odor about the entire contents. From all of which I concluded that death of the fœtus took place about two weeks prior to its delivery, *e.g.*, on March 20th, this being the day when such a profuse hemorrhage took place. After delivery the uterus contracted well, without any hemorrhage. For two or three days she was getting along very well, the lochia was abundant, yet natural; on the fourth day the temperature was decidedly feverish, she became restless, and complained of pain on her left buttock; the following day she had high fever, with great thirst, and complained of nothing but her left hip. I could notice nothing abnormal about the uterus nor the lochia. I examined her hip, saw only some slight redness, but not much tenderness. On the seventh day she had high fever, great tenderness over the gluteal region—could feel fluctuation of pus deep beneath these muscles. I made a deep and free incision, when more than a pint of offensive pus was liberated. Her suffering now ceased, as well as her restlessness. I inserted a tent for drainage, and left her until the next day, when her fever had disappeared, but the discharge of pus had been very profuse. At this time I used a probe to discover the extent of this abscess and its probable origin, and found that pus had burrowed to a considerable extent under the gluteii muscles, but found nothing to indicate its origin. A liberal diet with quinia and tincture of chloride of iron were the principal agents relied upon to sustain her strength. For two days more I continued my tents to encourage the free discharge of pus. She was feeling very comfortable, and had no fever. On the eleventh day Dr. Allan P. Smith examined the abscess, using a long uterine probe, and after considerable exploration it passed easily through the sacro-sciatic notch and then over the promontory of the sacrum in the direction of the spine to within half an inch of the entire length of the probe (which was more than twelve inches) before any expression of pain was elicited from the patient. At first we concluded that the formation of pus was probably due to caries of the spine, yet the termination of this case points directly to psoas abscess. At this time a drainage-tube was introduced, which she wore for a period of three months, through which an enormous quantity of pus was discharged, and after gradual expulsion of the tube the opening was allowed to heal. Her health and strength now improved rapidly, and her recovery was perfect. Menstruation made its appearance about two months after delivery, and continued perfectly regular and normal until February, 1877, at which time her second pregnancy began. During the whole term of this gestation she enjoyed excellent health.

On November 8, 1877, about two hundred and eighty days from the cessation of her last menstruation, her second labor began early in the morning and continued all day, and when I was called in the evening found the breech well engaged in superior strait, and in about two or three hours delivery was completed, the child, however, having died from asphyxia before the head could be delivered. Resuscitation proved ineffectual. Waiting a few minutes for contractions sufficient to expel the after-

birth, I very soon found myself compelled to interfere in effecting its delivery, because profuse gushes of blood accompanied the occurrence of each pain and contraction, which were very severe and frequent, and the effect of which was plainly visible at the pulse as well as by the blanched appearance of the face. I determined at once to introduce my hand into the uterus to remove the placenta, but in making this effort found the uterus and cervix so firmly contracted around the placental mass that I was unable to introduce more than my index finger, but with this I was enabled to diagnose morbid adhesions throughout its entire extent. I administered chloroform by inhalation until she was thoroughly anæsthetized, and then made another attempt. I succeeded, but not without some force, in introducing my hand into the uterus; but from the firm adhesions and strong uterine contractions, I was unsuccessful in detaching the placenta. Hemorrhage was not continuous, but at intervals quite profuse. Being extremely anxious, I made repeated efforts throughout the night, each one of which proved futile, and in all of which I had not made the slightest impression. I remained at the bedside throughout the night, administering stimulants frequently and at times adding ergot. When morning dawned, her pains were still frequent, but hemorrhage had almost ceased, owing, I judge, to her anæmic condition, there being not much more blood to lose. Uterus was as firmly contracted then as some ten hours ago. I then called on Dr. John Morris for his advice and assistance, to which he promptly responded. On his arrival we placed the patient under chloroform, and Dr. Morris made use of his best efforts to detatch and deliver the placenta; but after a very tiresome manipulation for nearly half an hour, decided that it could not be removed at this time without serious consequences to the woman; we therefore concluded to yield it to nature, and combat any untoward symptoms that might supervene. Hot-water injections were used repeatedly, without doing more than bringing away a few clots of blood. On the second day the discharges became very fetid; she complained of nausea, but had no vomitting and no hemorrhage, yet high temperature and pulse weak and frequent, all of which lasted for three days longer. Quinia and iron were tolerated by the stomach remarkably well. Carbolized hot-water injections were used frequently. Each disagreeable symptom became more intensified day after day, until the morning of the fifth day, when the placenta, in an extremely putrid condition, was discharged in four nearly equal segments. On examination I was still surprised to find the cervix, as well as the entire uterus, so firmly contracted that I could with difficulty only insinuate my index finger. I continued with my medicines, as well as vaginal injections, and the patient improved rapidly, and in about three or four weeks was on her feet again. She became quite strong and looked well.

Her menstruation again made its appearance in the latter part of February, 1878, and was in every respect normal. The next month passed without the appearance of her catamenia. Shortly afterward she had reasons to believe herself enciente. On April 30th, just two months from the cessation of her menses, she was taken with severe pains and a free discharge of blood. On my arrival, some hours afterward, found the product of conception, with secundines, in the cervix, which I had not much difficulty in removing, after which hemorrhage was only trifling and the uterus well contracted. I left her feeling very comfortable. About two hours afterward hemorrhage came on rather profuse, when I was again sent for, but, being professionally engaged, did not arrive until six hours afterward. During this time she had lost a great deal of blood, and I found her in an exhausted condition, with quite a free discharge of blood. I administered chloroform until anæsthesia was complete. I then introduced one finger into the uterus, with which I could detect a small, roughened elevation at the fundus, which I easily detached, and which proved to be of placental structure, scarcely larger than a nickel cent. Hemorrhage ceased immediately and did not recur again. It has been a question in my mind ever since whether the retention of so small a piece of placenta was the cause of so much flooding, or whether the same was caused by atony or inertia of the uterus itself, and whether or not hemorrhage ceased because of its removal, or was stopped by my finger as an irritating cause to produce contraction.

Her recovery was very much more tedious than on the other occasions. She had no fever at any time, yet general anasarca set in about a week afterward, and continued for nearly two months before she could be considered convalescent, but after this time her improvement was again rapid, and she regained her strength, and felt as well as she ever had done. For more than nineteen months she enjoyed good health, was never troubled by any discharge from the uterus or vagina, and during all this time did not even menstruate. I was several times consulted by her, whether I thought she would ever be unwell again, and was half convinced in my mind that she never would, yet on the 30th November, 1879, she noticed a slight show, lasting only one day, the first she had seen since her miscarriage in April, 1878. In the latter part of March, 1880, she thought herself pregnant, having experienced quickening, and, reckoning in the usual way, her confinement was expected about the first of September. Her health and appearance continued excellent during the whole term of pregnancy.

I now come to report the case under consideration. I was called in the early morning of August 15, 1880, just two hundred and fifty-eight days since her slight menstrual show. Labor pains had commenced the night previous, and had made sufficient progress for me to diagnose breech-presentation. Everything being favorable and normal, I thought I had time to leave her for some hours. When I returned at twelve M., found breech well engaged in superior strait, with expulsion pains in rapid succession. There was no occasion for any interference on my part, and in about one hour the breech and legs were expelled. But now the pains almost ceased, at least they only appeared at long intervals. Being extremely anxious about the life of the child, I made ordinary traction to facilitate its delivery, but in doing so found the umbilical cord on a tight stretch, impeding its progress very much, and in making repeated traction on the cord, which was still pulsating, I had to be very gentle, for fear of rupture on account of its unusual thinness and friableness. Pains had now ceased altogether, and nothing but involuntary muscular strainings assisted me in the delivery of the shoulders and head. The child was apparently dead, but after some prolonged effort, resuscitation proved successful. Before severing the cord, I introduced my hand into the vagina, and made a rather hasty examination, to ascertain the condition of the mother. Found a tumor, which I took to be the placenta, projecting through the os uteri, and

thought that the same had been separated from the uterus, and had partially entered the vagina, but had been impeded in its progress by a sudden and strong contraction of the cervix and os. There being no hemorrhage, I assured the mother that this time she need not fear any complications. I am free to admit that, had I recognized this tumor to be, as it undoubtedly was, a partial inversion of the uterus, I am sure I could have easily returned it, which would have prevented the formidable accident that presently occurred. I now tied and cut the cord, and handed the child to the nurse. The mother had had but one sharp pain since the delivery of the child. She had no hemorrhage, and expressed herself as feeling very well. I then took hold of the cord, and only made traction sufficient to guide me to the body of the placenta, and before I could place my other hand in position over her abdomen, she cried out that she had an awful pain, and at the same time pressed both of her hands in the lumbar regions, and with one quick, violent straining effort, protruded the uterus between her thighs, completely inverted, with placenta attached. Appreciating at once the enormity of the accident, I had recourse to ocular examination, and then saw this bloody tumor between her thighs. The placenta for the most part was situated at the fundus and on the right lateral and anterior walls of the uterus, all morbidly adherent, excepting for about a space two inches square, under which and from which the blood was welling up continuously, to an alarming extent. Being anxious to avert all possible danger from hemorrhage, and being entirely unprepared to meet with such an accident, I was governed by the impulse of the moment, and determined at once to remove the placenta before endeavoring to reduce the inversion. In my attempt to detach the placenta I found more difficulty than I should have ever anticipated. For, in spite of being able to use both of my hands, and with my eyes to guide them, some portions of the placenta would rather tear than separate from their morbid adhesions to the walls of the uterus; indeed, I had to make several efforts to detach some small portions after the great body of the placenta was removed.

Without wishing to digress, I would merely ask, if such was the difficulty in this case, how much greater would the difficulty have been had no inversion taken place? and may we not sometimes meet with cases where just such morbid adhesions occur, that it may be almost next to impossible to be able to remove the placenta? After having detached the placenta, I noticed an entire change of form of the uterus, depending upon unequal contraction of its muscular fibres. The anterior wall, with the right lateral and part of the fundus, was completely paralyzed, comparatively yielding and soft, being easily indented by my fingers, while the posterior and left lateral walls, and part of the fundus, were hard and resisting, evincing thereby their great contractile efforts. The soft and yielding portions constituted the placental site. Up to this time there had been no constitutional disturbance, no vomiting, no clammy sweats, no alarming distress, in fact, nothing to indicate any very severe injury, as are the usual symptoms of acute inversion. She only complained of an excruciating pain along the left leg.

I now commenced my effort at reduction, pushing the uterus into the vagina with my right hand, and supporting the cervix through the abdomen with my left. I made continued pressure until the body, followed by my hand, passed through the cervix. But at this moment a state of collapse ensued, respiration seemed almost suspended, and dissolution seemed inevitable. I withdrew my hand, which was very soon followed by complete inversion, removed the pillow and bolster from under her head, and was about to practice artificial respiration had not the breathing been re-established. She called for water, but swallowed a large drink of brandy at my suggestion, which in a short time I had repeated, from the effects of which the heart's action became stronger. This state of collapse, no doubt, was in a great degree owing to the profound shock on the nervous system, and quite independent of the loss of blood she had sustained, because the hemorrhage, though excessive, was not as profuse as had been the case in her former accouchements. After reaction had fully set in, she expressed herself as being more comfortable. There was no undue hemorrhage, yet the inverted uterus was still in the vagina. Under these trying circumstances, being without any intelligent assistance, I felt myself unequal to the task before me, and sent for Prof. A. F. Erich, who, being professionally engaged at the time, did not arrive until a little after four o'clock. While waiting, I had to administer brandy repeatedly, and made another attempt, without chloroform, to reduce the inversion, but it gave her so much pain that I had to desist. At this time hemorrhage came on quite profusely, and I was only able to check it by swabbing the womb with a sponge soaked in a solution of subsulphate of iron and glycerine, and allowed the same, with two others saturated in the same solution, to remain in the vagina.

I am under great obligations to Dr. Erich for his promptness in responding to my urgent request, and also for his subsequent advice and assistance. At the time above mentioned Dr. Erich arrived, and brought with him Dr. Rohe, to administer the anæsthetic. Without wasting much time in deliberating, he prepared himself for the operation. After the patient was thoroughly under the influence of chloroform, he removed the sponges and some clotted blood, and then introduced his right hand into the vagina, grasped the body of the uterus, and with his left hand supported and dilatated the cervix through the abdominal walls, and returned that part which had been inverted last, until the entire uterus, with his hand following, had passed through the cervix. This manipulation lasted about ten minutes. He allowed his hand to be enclosed by the uterus, for the purpose of stimulating contraction, nearly half an hour, during which time I used the hypodermic syringe six times, injecting deep into the abdominal muscles about two drachms of fluid extract of ergot before any contractile effort of the uterus could be experienced. After this his hand was carefully withdrawn. The patient, still suffering from the combined effects of shock and loss of blood, was made comfortable with her head in a depending position, her pelvis and lower extremity being raised by raising the foot of the bedstead. The time had at last come for me to be able to leave her, and the sense of relief can be better imagined than described. I was absent about four hours, during which time she had had no hemorrhage, yet seemed very restless. I gave her a hypodermic injection of ten minims Magendie's solution of morphia, which had a very quieting effect in a few minutes.

I now left her for the night, in a condition as comfortable and cheerful as could be expected under the circumstances. Dr. Erich continued to visit the patient with me for several days, and I cannot but

acknowledge the deep interest he evinced in this case, as well as his many valuable suggestions as to treatment during our consultations.

August 16th.—She has passed a quiet night; lochia scarce; slight tympanitis; passed her urine without difficulty, pulse, 140; temperature, 101°. The anterior wall of the uterus, where the placenta had been attached, showed the same evidence of paralysis, being relaxed and quite flabby, and lying in the cervix. She had had some slight after-pains. Ordered vaginal injections of carbolized hot-water every six hours. Quinia and tincture of chloride of iron were given every four hours with concentrated liquid nourishment. At my evening visit found temperature, 102°; pulse, 150; lochia more abundant, great tenderness over abdomen with sick stomach. Gave hypodermic injection of twelve minims Magendie's solution.

August 17th.—Passed a comfortable night. Temperature, 101°; pulse, 120. Lochia very fetid. Os uteri dilated to admit two or three of my fingers, with the paralyzed anterior wall still pressing into the enlarged cervix. Abdomen very tympanitic, for which small doses of calomel were ordered every two hours, to be followed by an enema of turpentine and soapsuds the following morning. For the fetid lochia I ordered boracic acid suppositories, to be placed in the vagina every six hours, one of which, at the suggestion of Dr. Erich, I introduced into the uterus, which had the effect of rendering the discharges from vagina almost odorless by the next morning.

I have no desire to make this report unnecessarily long, by giving a detailed account from my notes for every day I visited her. I will, therefore, only mention the most prominent points of interest. For more than a week her average temperature remained at 101°, without any other febrile symptoms. Her pulse ranged from 110 to 120. Gastric disturbance and tympanitis disappeared in a few days. Her uterine discharges became quite natural after a continued use of boracic acid suppositories. Systemic treatment was conducted from day to day upon the expectant plan. She nursed her baby regularly, and had sufficient flow of milk for its nourishment. The uterus, however, remained for several days in a state of imperfect involution. Daily examinations per vaginam, revealed a continuance of paralysis of its anterior wall, which in a flabby state remained flexed into the cervix, while the rest of the organ seemed hard and resisting and well-contracted. This condition of the uterus lasted until August 27th, when I noticed that the paralyzed portion had regained its proper tone and the whole organ was in its natural position. Her general condition had also improved, her pulse was less frequent, and her temperature normal. Her convalescence was tedious, yet her recovery perfect.

---

THE SPIDER'S WEB AS AN ANTIPERIODIC.—In the *Gaceta Medica*, of Sevilla, Sr. Oliva, from personal experience and from that of others in ninety-three published cases, concludes that the secretion of the spider is of therapeutic value in malarial fevers of quotidian and tertian type. Given in quantities of two grammes to adults and one gramme to children, two doses generally suffice to cut short the disease and prevent relapse. It is recommended on account of its tastelessness, but until further data are collected, is not to be administered in pernicious fever.

## DO THE AURICLES ACTIVELY CONTRACT?

BY G. A. HARMAN, M.D.,
LANCASTER, OHIO.

THIS is a question that has been answered in the affirmative from the time of Harvey, who said, "First of all, the auricles contract," by all writers upon the subject until now. Drs. Dalton, Flint, Foster, Gray, Loomis, in fact, all modern writers agree that they do. So universally is it accepted, that it appears iconoclastic to call the matter in question. But we think there are very grave reasons for doubting their contraction, if, indeed, they are not sufficient to prove that they do not.

By contraction we mean their active participation in the act. We freely admit that they contract, but claim that it is passive.

Our reasons for entertaining a belief contrary to that universally accepted are, first, anatomical, and second, mechanical.

*First.—a.* The auricles are composed chiefly of serous and fibrous tissue, and, unlike the ventricles, have very little muscular fibre, and it is muscular fibre only that is capable of active contraction.

We find the auricles have but two thin layers of muscular fibre, the outer of which is incomplete; and an incomplete circular muscle is powerless. Divide a sphincter muscle and its utility is destroyed; so, then, in the auricle, we have but one layer capable of exerting force, and that layer so thin that, compared with the labor to be performed, it seems to us incapable. The muscles of the auricles are not nearly so well developed as those of the ear, which in the human subject are only rudimentary.

If we descend the scale of animal life, we should doubtless, way down the line, find animals the construction of whose hearts demanded, and which do have well-developed auricular muscles. *b.* The auricles have only about two-thirds or three-fourths the capacity of the ventricles. *c.* The auriculo-ventricular openings, those of exit, have two or three times the area of the venous openings, those of entrance. *d.* The veins in neither auricle, with the exception of the vena cava ascendens, have valves which would seem to be necessary, if the auricles were intended to contract,

*Second.*—Mechanically, their contraction appears to be unnecessary, as the ventricles are able to perform the work of circulation, as will be shown. Indeed, experiments have already been made showing that the circulation can be carried on without their contraction.

A year or so ago, an article appeared in *The Monthly Abstract of the Medical Sciences*, relating the case of a horse, which died after a few hours' illness, the effect of an over drive. The post-mortem revealed ossification of both auricles. This ossification could not have been the result of the last illness. It being a slow process, must have existed for months, and possibly years. Before the drive the animal was in apparent good health, and, if healthy, with auricles that did not contract.

*a.* If the auricles contracted, they would exert force in every direction; the veins having no valves, the influx of blood through them would be arrested, if not made to regurgitate, producing constantly recurring temporary congestions of the lungs and brain. *b.* The influx by the veins being arrested by the contraction, the auricles could only discharge their contents, which, because of their less capacity,

would be insufficient to fill the ventricles, and the ventricles would fail to receive that natural stimulus to contraction, viz., distention, and inefficiency would result from their partial filling. *c.* If a hypodermic needle be thrust into the ventricle, the blood spurts up through it to a considerable height during the contraction; but if the needle be thrust into the auricle, the blood at no time more than wells up through it.

I now present my idea of the heart's action, as formed from a consideration of the anatomy of the heart, and the mechanical laws which govern it.

The ventricles contract, and their contents are expelled (during their contraction the auricles are being filled), then they dilate by their resiliency, like a rubber-ball, and vacuums would be produced but for the rush of blood from the auricles. expelled, not by auricular contraction, but by atmospheric pressure.

The capacity of the ventricles being so much in excess of that of the auricles, and the auriculo-ventricular openings (those of exit) being so much greater than those of the veins (those of entrance), the blood is withdrawn from the auricles much more rapidly than it is supplied. The walls of the auricles being too thin to withstand the atmospheric pressure, follow down (collapse) the diminishing volume of blood, producing an apparent contraction, which Dr. Dalton describes as "short and feeble," and Dr. Flint as "quick and powerful."

To illustrate: Do the two balls of a syringe, in using, have to be compressed alternately?

If you wish to throw an intermittent stream (as do the ventricles), and compress the distal ball (the one farthest from the operator), will it not recover itself (as do the ventricles), and refill *from* the proximal ball, without its having to be compressed?

Suppose, now, that the walls of the distal ball were active and strong, and those of the proximal were thin, with little resisting power, and its outlet much greater than its inlet (as is the case with the auricles). If, now, the distal ball be compressed and suddenly released, it springs back to its globular form; the suction force it exerts on the contents of the proximal ball causes the ball to collapse, because its walls are too weak to sustain a vacuum, and its opening for admission of fluid is too small to supply the immediate demand. So with the auricles, their contraction, or rather collapse, is entirely passive, and they sink to the position of reservoirs, from which the ventricles draw their supplies.

---

CHLORAL HYDRATE IN DYSENTERY.—Dr. Curci has obtained good results from chloral in the treatment of typhoid diarrhœa and dysentery. In the latter disease, the remedy is combined with chlorate of potassium. It may be given with barley meal, by the mouth (from one to three grammes daily, in the case of an adult), or in the form of clysters, ten grains of chloral to two litres of the meal sufficing for ten of these. Before administration by the mouth, a light purge should be given. Dr. Curci states that chloral is not only narcotic, but also sedative, astringent, anti-diarrheic, coagulant, and hence, antiseptic. It calms the cerebro-spinal centres, as well as the sympathetic, which latter, above all, is affected in dysentery. By reason of the sedative influence of the remedy over the sympathetic, the peristaltic action of the intestines is diminished, after being temporarily increased, and the pain is made to disappear.

# Progress of Medical Science.

SOME OF THE RECENT INVESTIGATIONS INTO THE SCALA MEDIA COCHLEÆ.—Mr. C. S. Minot has collected some of the recent facts bearing on this topic (*American Journal of Otology*, April, 1881). Böttcher, Gottstein, Kölliker, and others have placed the matter in its present tolerably clear light. The cochlea grows downward and inward from the lower side of the primordial vesicle. It assumes the form of a flattened canal, and it is this canal which elongates and coils until the scala media is finally formed. The histological development of the cochlea progresses most rapidly at the base. The epithelium is at first changed in the height of the cells, being thinned out on the upper side, forming the lining of one side of the membrane of Reissner. The lower portion remains thick, and forms the crista, sulcus, and organ of Corti. As a second change, the epithelium on the under side, or wall next the scala tympani, thins out, having two thick epithelial ridges of unequal dimensions. The larger lies nearest the columella, and forms the lining of the sulcus spiralis. It soon acquires a thick cuticula—the beginning of the membrana tectoria. The smaller ridge becomes the organ of Corti, including the supporting cells, inner and outer hair-cells, and Corti's rods. Very shortly after the distinct formation of the ridges, the lamina spiralis begins to grow up between the sulcus, and the axis of the cochlea develops into the crista. In the smaller ridge are found four sets of cells arranged longitudinally. From the first row are formed the inner hair-cells; from the second, Corti's rods; from the third, the outer hair-cells; and the fourth furnishes the supporting cells.

PROGRESSIVE FACIAL HEMIATROPHY.—Dr. J. Workman (*Alienist and Neurologist*, April, 1881) presents a very interesting account of a case of this kind which occurred in the practice of Prof. Maragliano, of Genoa. The atrophy appeared to be the result of an injury received during early infancy. The patient, when a year old, had a fall, striking the left half of the face. This was followed by swelling and the other characteristics of contusion, which lasted for a few days, and then disappeared. After a time the left side of the face appeared diminished in size. It continued to diminish till the patient was ten years old, when she came under the care of Prof. M.

The patient was well developed in other portions of the body, and well nourished. The muscles of the left cheek were so extremely attenuated that the skin and mucous membrane appeared to be directly applied to each other. The part was so thinned and so adherent to the bone that it was impossible to raise a fold of the skin. The faradic current was applied for something over three months, when, on account of the closing of the clinic, the patient was lost sight of. The improvement in the part was very marked; there was still a difference in the two sides, but it was slight. The tissues of the left cheek had notably thickened, were almost equal to the sound side, and it was possible to raise quite a large fold of skin.

A CASE OF DEATH FROM CROUPOUS INFLAMMATION OF THE MIDDLE EAR, WITH ACUTE SEPTO MENINGITIS OF CONVEXITY.—Dr. E. G. Loring reports an interesting case of the above (*American Journal of Otology*, April, 1881). The patient was a middle-aged man of full

habit, who had suffered at intervals for two years from severe colds in the head accompanied with great pain in the right ear. The attacks usually yielded to treatment. On April 13, 1880, he presented himself, complaining of great pain in the right ear and the whole side of the head, this was accompanied by such extreme deafness that he could hear the watch only when in direct contact with the ear. He presented all the physical signs of commencing trouble of the middle ear. He experienced great relief from the application of leeches, and passed a comfortable night. In the course of the next day, however, the pain returned, but was more in the ear than the head; later in the day he became very delirious and violent, with labored but not stertorous breathing, the face was livid, and pulsation in the jugulars was very marked; there was no paralysis. The pupils were moderately dilated. There was some slight bulging of the membrana tympani, but less injection than on the previous day. The drum was punctured, but with a negative result, even after the application of suction. The patient sank rapidly and died in about an hour. The necropsy developed the following: There were a few atheromatous patches on the arch of the aorta, the spleen soft, but not swollen, otherwise the viscera were normal. On examining the cranium, the various sinuses contained fluid blood and coagula, but no ante-mortem thrombi. The dura appeared normal, save over the right tympanic cavity, where it was deeply congested and presented numerous points of punctate hemorrhage. There was congestion and a moderate amount of a yellowish, seropurulent exudation over the cerebral hemispheres, and a thick, yellowish, creamy patch upon the upper surface of the right lobe of the cerebellum, near the anterior and lateral borders. The substance of the brain appeared normal. The mucous membrane of the middle ear was softened, swollen, of a bluish red color, coated with a false membrane, and presented the appearance of croupous inflammation.

Vicarious Menstruation from a Sebaceous Tumor of the Meatus Auris.—Dr. J. O. Green (*American Journal of Otology*, April, 1881) presents an interesting history of what appears to be an unique case. The patient was a young lady, who complained of an occasional bleeding from the right ear. Six months before, she had had what she called an abscess of the ear. On examination the ear was found normal, save a very slight prominence just at the edge of the right meatus, which was supposed to be a thickening left from the furuncle. The patient was seen again about three years after, the bleeding had increased, and the doctor was informed that it occurred at the menstrual periods. The ear was found normal, excepting, that at the seat of the former thickening, a distinct sebaceous tumor, the size of a bean was found. From the appearance of the skin over the tumor, and the assertions of the patient and her mother, Dr. Green believed this to be the seat of the hemorrhage. The tumor was removed, and after five months there had been no return of the bleeding.

A New Ventilating Trap for the Prevention of Sewer-Gas.—Dr. Railton, Medical Officer of Health (Report to the Withington Local Board for 1880), thinks he has found in the use of Pott's ventilating trap an excellent medium for the prevention of sewer-gas entering apartments. Until recently it has been a problem unsolved to sever completely the connection between the closets and the sewers, and the only means heretofore adopted to take off the pressure of sewer-gas from the trap in the soil-pan was by providing a ventilating shaft at the top of the soil-pipe. This difficulty has been removed by the use of Pott's ventilating trap. It is made of earthenware, and consists of three parts. That nearest to the house is an open chamber, the bottom of which has a slope of the same gradient as the drain into which it passes; its top is level with the ground and is covered in by a movable grating. Beyond this grating there is a gully bend, which cuts off its connection from the drain by means of the water which it holds. This bend is so placed that it can be cleansed out, if required, through the compartment which is open to the air. Between the gully bend and the drain there is a ventilating shaft, which is intended to take off as much as possible the pressure of sewer-gas from the water in the bend. It will thus be seen that there are no less than three safeguards interposed between the interior of the sewer and the interior of the house. With the combined action of all three, there is not the shadow of a chance of any sewer-gas finding its way into the water-closet. The ventilating shaft might be insufficient by itself to prevent the gas passing up the soil-pipe, especially in times of great pressure within the sewers, as, for example, after a heavy rain, but the water in the bend offers a resistance to its passage upward. Should it nevertheless succeed in forcing its way through that, it passes into the open chamber, and thence through the grid into the air. Dr. Railton was inclined to think an objection to the use of this trap was that through the open grid a smell might be perceived every time the closet was used. This objection, however, was found to be without foundation. There is no smell whatever; the rush of water along its sloping bottom takes place so rapidly that the fæces are carried past the opening and into the drain too quickly for any smell to become perceptible, even if one happens to be close to the grid at the moment. He has had this trap applied to the drain of his own house for the last three months, and has found it satisfactory. Before that time, the water-closet acquired a peculiar stuffy smell if the window was allowed to remain closed, although the soil-pipe had a ventilating shaft of large diameter carried up above the eaves of the roof; and when the plug was pulled up, thereby temporarily destroying the trap in the pan—there was a decided rush of sewer-gas upward into the room. The application of the trap has effectually removed all this. During the severe frost the window was kept nearly constantly closed, and the gas was lighted both during the night and day to prevent the water freezing in the cistern; despite this crucial test there has never been the faintest approach to a smell.

Ocular Symptoms in Different Diseases.—Dr. Gorecki, as quoted in the Glasgow *Medical Journal*, has tabulated his views as follows:

Blepharoptosis, or the falling of the upper eyelid, indicates paralysis, complete or incomplete, of the third pair.

Lagophthalmos, or inability to close completely the palpebral fissure, is a sign of facial hemiplegia, idiopathic, or a symptom of cerebral disease.

Strabismus, occurring suddenly and accompanied by diplopia, is most frequently the result of some cerebral affection.

Xanthelasma (a yellow lamina sometimes met with

in the skin) of the eyelids occurs in certain alterations of the liver.

Subconjunctival ecchymoses are frequent in whooping-cough, and may sometimes, at the beginning of the complaint, clear up a difficult diagnosis.

Redness of the conjunctiva, watering of the eye, etc., indicate in the child the outbreak of some eruptive fever, particularly measles. The prognosis is favorable if the tears come when the child cries, but fatal if the secretion of the tears is arrested.

Spots on the cornea are often the indication of a strumous constitution.

Dilatation of the pupil, or mydriasis, indicates excessive fatigue, the existence of intestinal worms, meningitis in the second stage, or a true amaurosis. The dilatation is most frequently connected with atrophy of the optic nerve. It is seen also during an attack of epilepsy, on coming out of chloroform, after belladonna-poisoning, etc.

Unequal dilatation of the two pupils points to the onset of general progressive paralysis.

Contraction of the pupil is one of the early symptoms of tabes dorsalis. It is met with also at the beginning of meningitis, in opium-poisoning, and in chloral-poisoning.

Deformation of the pupil, particularly after the injection of atropine, indicates an old iritis, in nine cases out of ten, of syphilitic origin, if not depending on some disease of the neighboring parts.

Cataract in subjects under, say forty of fifty, is frequently of diabetic origin, and constitutes soft cataract.

Finally, the ophthalmoscope enables us to recognize the retinitis associated with Bright's disease. Retinal hemorrhages, œdema of the retina, and embolism of its central artery, are sometimes met with in organic affections of the heart. Optic neuritis and perineuritis and atrophy of the disk are symptoms of syphilis, or of tumors in the neighborhood of the cerebellum or the corpora quadrigemina.

THE ABSORPTION AND ELIMINATION OF QUININE.—Professor Lepidi-Chioti has made a series of experiments on the absorption and elimination of quinine, and comes to the following conclusions: Quinine is not eliminated with the saliva or sweat; it is not absorbed through the skin; administered hypodermically it appears in the urine after thirteen to fifteen minutes; taken by the mouth it appears after fifteen to seventeen minutes; given by the rectum it may be detected in the urine after twenty to twenty-five minutes.—*Gazette des Hôpitaux*, March 5, 1881.

TREATMENT OF SKIN AFFECTIONS BY THE METHOD OF OCCLUSION.—In an elaborate monograph on this subject, M. Busquet explains the advantages of the system of occlusion in the treatment of certain dermatoses. The following are some of the author's most important conclusions in regard to this matter. Skin affections invariably have a debilitating influence on the body, and they demand active intervention. Topical applications to the cutaneous surface are frequently unreliable in their effects. A notable exception is to be made in favor of Hebra's ointment, which, however, acts rather by occlusion than in virtue of its medicinal constituents. The good results following the employment of occlusion appear to be independent of the material used to bring it about. Caoutchouc, or cotton-batting, or Mackintosh material, will all be found serviceable. Even if the entire body is enveloped, the method will prove innocuous, for the temperature of the body is increased thereby, whereas animals whose cutaneous surface is covered over with varnish die from the effects of cold. If a diathesis underlies the skin affection, of course constitutional treatment must be combined with the local measures. Although treatment by occlusion is useful in acute cutaneous affections, it is to be employed principally in the chronic varieties of skin disease, and especially in cases where other therapeutic measures have been found unavailing. In children the entire surface of the body should never at any one time be completely covered by the occluding material. The method may be used both in the dry and moist forms of eruptions. It is of great utility in attempts to overcome inflammation and pruritus.—*Lyon Médical*, April 10, 1881.

"GALLOPING" CARDIAC RHYTHM.—At a meeting of the Berlin *Verein für innere Medizin*, Fräntzel read a paper on the above subject, of which the following is a brief abstract. The symptom under consideration consists of the occurrence of three heart-sounds for each beat, two of which belong to the diastole. In this way the cardiac sounds imitate the distant clatter of a galloping horse's hoofs. Bouillaud has been generally credited with having first called attention to this symptom, but Fräntzel asserts that what that author described as *bruit de rappel* resembled rather the beating of drums than the present symptom. Potain had indeed already described this phenomenon, but had erroneously interpreted the second diastolic murmur as a presystolic one. He had spoken of a double systolic murmur, and had, among other things, considered it characteristic of incipient contracting kidney. Johnston recognized the occurrence of galloping rhythm, and thought he had observed it in connection with bronchitis and pulmonary emphysema. Traube distinguished it from the occurrence of a double diastolic murmur, the second sound of which was said to be synchronous with the auricular contraction, but he failed to explain the symptom in a satisfactory manner.

Now, Fräntzel states that the murmur of galloping rhythm is heard with equal intensity over the entire cardiac area. The accent of the three sounds lies on the second or third one. It may be readily distinguished from other, real or false, double sounds. So Fräntzel says, at least, although he fails to give explicit particulars, only repeating the resemblance the galloping rhythm bears to the clatter of hoofs. At any rate, it has no relation with valvular diseases of the heart. It may be present in general cardiac enlargement due to chronic affections. But it is especially frequent in connection with pneumonia, typhoid fever, pernicious anæmia, and other similar diseases. In such cases an anatomical basis for its presence cannot be made out. Most frequently, however, Fräntzel observed this symptom in morbus Addisonii, associated with a tendency to syncope. And he regards it as a sign of grave prognostic importance, denoting, as it does, extreme cardiac feebleness. In other affections, likewise, weakness of the heart is accompanied by galloping rhythm, and hence the prognosis of a case depends upon, or may be modified by its presence. Concerning the ultimate physical mechanism of its origin, Fräntzel is not able to adduce positive facts.—*Allgem. med. Central-Zeitung*, March 30, 1881.

THE RHODE ISLAND HOSPITAL at Providence, R. I., has just received an endowment of $4,000 from the late Cornelius Sullivan.

# THE MEDICAL RECORD:

## A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 23, 1881.

## RECENT PROGRESS IN THE MEDICAL USES OF ELECTRICITY.

ELECTRICITY has not as yet attained a very wide range of usefulness in medicine or surgery. The cost, the inconvenience, and the lack of knowledge, have had something to do with this. And besides, the intrinsic value of the agent is undoubtedly less than was at first supposed and hoped.

There seems, however, just now to be an effort from various quarters to bring electricity into the greatest possible prominence. And an impetus has been given to its medical uses, as well as to its practical applications elsewhere. It is of interest to medical men to follow this development of our mastery over electricity in whatever direction it tends. In the causation and prevention of disease we can already see its workings. Electrical lights as now made, when used for reading, cause retinal congestion; but, on the other hand, leave a purer air. The telephone, like the telegraph, facilitates business, and takes away some of the friction of life; but it makes life faster and disturbs its healthy equipoise. There are now claimed to be practical methods by which we can make of electricity a motor power. This will diminish noise and smoke, soothe the nerves, and spare the horses, and variously modify our modes of travelling, manufacturing, and living. It, like other inventions which are real innovations, will thus have some indirect relation to medicine.

But there has been a discovery of comparatively recent date which has a more direct bearing on the uses of electricity in medicine and surgery. This is an apparatus for storing electricity. It was first invented by Ritter, of Liegnitz, was improved by Planté, and subsequently improved by M. Faure, of Paris. Trouvé seized upon the apparatus and applied it to purposes of illumination and cauterization. A description of his apparatus, given at the Academy of Medicine some weeks ago by Dr. Elsberg, was reported in these columns. Objections were raised against the Planté battery, however. It was said to be expensive, irregular in action, and not sufficiently strong. These defects made it doubtful whether the apparatus would be of very much utility. Lately, however, several inventors claim to have devised improvements which do away with most of the objections advanced.

The instrument, as perfected, is as simple in construction as it is novel and extraordinary in its powers. It consists of sheets of lead, rolled up and kept slightly separated by strips of wood or other substance. The coil is then immersed in water acidulated with sulphuric acid. According to the descriptions furnished, which are as yet imperfect, the minium with which M. Faure artificially coats the sheets of lead used in constructing his battery, others develop upon the surface in the process of charging, and by some other modifications, principally chemical in their description, correct the development of gases and reduce the cost of the plant very materially.

The charging is done by passing a current of electricity through the coils. This changes the minium (which is a mixture of lead monoxide and dioxide) into the dioxide on the positive pole, and to reduced lead at the negative pole. When fully charged, the battery is sealed. It may then be laid away and no reactions will take place. Upon connecting the poles, however, electricity is developed in a regular and powerful current, the latter depending on the size of the battery. An apparatus weighing one hundred and fifty pounds will develop electricity equal to seventy-five kilogram-metres, in one hour. In thus discharging itself, the reduced lead appears to be oxidized and the peroxidized lead reduced.

One experimenter, Dr. Higgs, states that, with his apparatus, the quantity and tension can be perfectly regulated, and that the variation from beginning to end is not over twenty per cent. He has used his instrument for medical and surgical purposes, and has also devised a lamp to go with it.

The practical applications of this new invention to medicine are as yet undetermined. But they promise a good deal, especially in the matter of illuminating cavities, of cauterizing, etc. At present the item of cost is not determined, and it may prove a serious bar to a wide use of the apparatus.

In connection with this subject of progress in electricity we should mention the recent revival of static electricity by Charcot and Vigoreaux, in Paris, and by Morton, Bartholow, and others, in this country. One fatal objection to franklinism heretofore has been that, owing to imperfect instruments, the electricity could not be obtained at all times. This has been largely obviated, and a powerful as well as constant supply of sparks can now, it is said, be

furnished. We have heard, however, that some of the best instruments have failed during the present hot season.

The introduction of these new machines has given a fresh impetus to the study of this particular form of electricity. So far, it has been found that they will secure, more conveniently, some of the effects which galvanism and faradism have before produced. Whether franklinism has any specific value not possessed oy other forms of electricity remains to be proved, and seems somewhat doubtful. The mental effect, however, of having the hair stand on end and of seeing lightning play around the room, is very great, and no doubt is often useful. The discovery by Dr. Morton of a method by which an induced current can be obtained from the instrument adds to its range of usefulness.

---

### THE PREVENTION OF DISEASE BY INOCULATION.

THE suggestiveness of the fact that a malignant disease, like small-pox, can be prevented by the inoculation of a harmless virus, seems to have been felt very strongly of late.

Within the past few years there have been announced methods of protective inoculation against five or more different diseases, not including pleuro-pneumonia. These diseases are: chicken-cholera, anthrax, "black leg"—a disease resembling anthrax—a peculiar septic fever, and the poison of certain fungi. They all occur in the lower animals, and are more or less akin pathologically. The evidence that the diseases in question can actually be prevented by inoculations is not of the best in every case, but the claims that are made are very positive, and there have certainly been obtained some striking results.

The methods by which the protective virus is obtained vary in different cases. Thus, Pasteur puts what he considers the specific germ of chicken-cholera and of anthrax through a series of prolonged cultivations; Greenfield, in experimenting with splenic fever poison, inoculates it in guinea-pigs, and then uses the secretions from these animals upon healthy heifers; Davaine heats the infectious secretion of anthrax with a little carbolic acid, and then injects it into healthy sheep. Koch, like Greenfield, cultivates the septic virus of one animal in the organism of another. Kajewsky, in his experiments with septic virus, heated it to 55° C. for ten minutes, and then injected it into healthy animals.

P. Grawitz has recently made some interesting experiments with a specially cultivated mould. This mould, in its natural condition, is harmless, since it cannot live in the blood. By carefully cultivating it, however, in warm and alkaline fluids, it finally adapts itself to the new medium. If then injected into the veins of an animal, it rapidly multiplies, and generally causes death. If a very small amount be injected, however, the animal recovers and subsequently has an immunity against further injections. Grawitz's experiments throw considerable light upon the manner in which preventive inoculations act, but upon this subject we cannot enter.

As may be seen, the methods by which the poison of a disease is modified so as to act as a preventive against further attacks are not uniform. There is only one thing in common, and that is that the virus is lessened in amount or virulence. What other modifications are necessary it is impossible to say. In some cases, as in the mycosis experimented with by Grawitz, and in pleuro-pneumonia, there is a small amount of the virus inoculated, and the result is simply a mild form of the disease. In other cases, it seems probable that the virus and the resulting disease are modified in character.

The method of modifying virus which has secured the best-established and most practical results is that used by Burdon-Sanderson and Greenfield. These experimenters worked upon the theory that the cultivation of the virus in the organism of animals not ordinarily attacked by the special disease would modify it and make it protective.

We have recently received a letter from Dr. Wesley Miller, of this city, in which he claims priority in this idea, as well as in that of preventing diseases generally by vaccination. In 1873, Dr. Miller argued the possibility of preventing tuberculosis in man by inoculation of some modified form of bovine tuberculous matter. He further states that, while he was in South America, a physician, acting upon this idea, made some experiments upon the native Indians. He took the matter from the lung of a tuberculous cow, and made several successive "cultivations" of it in other healthy animals. It was then inoculated in tuberculous Indians, with, it is stated, favorable effects.

All this seems wild and unjustifiable experimentation; but, whatever its worth or its results, it undoubtedly involved the principle which is now so extensively adopted by European experimentalists. Dr. Miller seems entitled, therefore, to the credit of priority in the idea—an idea which is, of course, only the natural corollary from the facts of vaccination.

The same gentleman asserts, but on insufficient evidence, that foot-and-mouth disease in the cow is identical with scarlet fever in man. The possibility of obtaining a protective virus for this latter disease is therefore suggested.

Referring to the antagonism of animal poisons, Dr. Miller states as a fact that the Mexican Indians inoculate themselves with the poison of the rattlesnake, and in this way believe that they are protected from all venomous snakes.

He also says that he was stationed at one time on a vessel that was lying off Callao while yellow fever was prevailing in that port. Several persons who

did not go ashore, and who were not exposed at all, caught the fever very mildly indeed, but sufficiently to protect them. Others who went ashore were taken very severely.

We repeat these statements of Dr. Miller's for what they are worth. They may at least help to create an interest in a subject that certainly deserves investigation. The usefulness of preventive inoculations has been established in two diseases: small-pox in man and pleuro-pneumonia in cattle. It remains to be seen whether the method has not a much wider application.

### THE WOUNDED PRESIDENT.

THERE has been a continual improvement in the President's condition since our last issue, and at present writing there is little doubt of his ultimate recovery.

We have published elsewhere a chart showing the range of temperature, pulse, and respiration. It will be seen that the fever gradually increased until the 12th instant, when it reached its maximum. From that day it began to decline more or less regularly. On the morning of the 13th, it was normal for the first time. The pulse and respiration showed no unusual change. The patient has had few bad symptoms of any kind. He has shown some restlessness and has experienced some pain, but has of late improved in each of these particulars. On the 17th there was a slight gastric disturbance, which rendered a lessening of his diet necessary. The appetite has, however, on the whole, been improving. The bowels are kept open by enemata.

The diet of the patient has been mostly of a liquid character: meat-juice, milk, etc., with toast, and sandwiches of scraped raw beef. Rum, Tokay and port wine have been given in small quantities. The medication has consisted of morphine at night and bisulphate of quinine in ten to fifteen grain doses. The wound continues to be dressed antiseptically twice a day. It discharges several drachms of laudable pus. Microscopic examination of this pus has, so far as we can learn, failed to show that there is any bile or liver-debris in it. The drainage-tube can now be pushed four and a half inches into the wound. Pressure upon the side of the abdomen below the wound brings out pus. No positive facts regarding the course or position of the bullet have yet appeared.

It is stated that certain electricians went to the White House last week with an electro-magnetic apparatus which it was thought might indicate the position of the bullet. But no success has as yet been reported.

The fact that the President is lying ill in a hot city has given a great impetus to the invention of cooling apparatus. With one of these the air of the patient's room is now kept at any desired temperature.

## Reviews and Notices of Books.

THE DISPOSAL OF THE DEAD. A Plea for Cremation. By EDWARD J. BERMINGHAM, A.M., M.D. 8vo, pp. 120. New York: Bermingham & Co. 1881.

IF the recent formation of a joint stock cremation society in our city is to be taken as a criterion of increasing interest in the question of the incineration of the dead, Dr. Bermingham's very interesting and instructive book arrives *à propos* to enlighten the public mind upon the subject. Regarding as axiomatic the assertion of Sir Henry Thompson that "no dead body is ever buried within the earth without polluting the soil, the water, and the air around and above it," the author endeavors quite successfully to convince the skeptic mind that our present system of disposing of the human dead is fraught with danger to the living. The book contains the following chapters: I. Different Methods of Disposal of the Dead; II. The Evils of Burial; III. History of Cremation; IV. Cremation from a Sentimental Point of View; V. Description of Cremation and Apparatus; VI. Cremation of Dead Animals and of Garbage; VII. *Résumé* of Arguments For and Against Cremation. Regarding the question of incineration from a sentimental point of view, the author combats the feeling of repugnance which the prejudiced mind experiences at the thought of cremation, by holding up a rather striking picture of the human body undergoing progressive decomposition in the ground. He asserts that all the rites and ceremonies with which the living are wont to express their feelings for the dead are as applicable to the new system as to the old. In his sixth chapter, the author touches upon a subject which interests every New Yorker—"the present plan of collecting garbage periodically, or rather spasmodically, and dumping it into the sea." He hopes that our legislators may be made to mend the error of their ways, and to bring about a much more economical plan of disposing of our refuse—by the process of incineration. The book is not remarkable for its originality, but its presentation of facts is systematic, the arguments are sound, and the conclusions legitimate. It is written in a pleasant entertaining style, and will doubtless command a wide reading.

TRANSACTIONS OF THE THIRTIETH ANNUAL MEETING OF THE ILLINOIS STATE MEDICAL SOCIETY, held at Belleville, May 18, 19, 20, 1880. Chicago: C. H. Blakely & Co.

THIS book contains quite a number of creditable papers. Dr. Haller presented an interesting report of an extensive epidemic of mumps which occurred, during the autumn of 1879, in Vandalia and vicinity. Among the adult males metastasis to the testes was the rule, and in young boys it was quite common. Metastasis was exceedingly rare among females, and failed to occur in any of the young girls who came under Dr. Haller's observation. Brain complications were quite frequent among young boys. Quotations from standard authors showed that they regarded the disease as one of little significance, and the metastasis to the testicle as a favorable sign. The deductions drawn by Dr. Haller from the Vandalia epidemic do not, however, agree with these statements. In his experience, the mildest cases were those in which there was no metastasis to the testicle. He

has seen the virility of that organ destroyed in cases that came under his notice. Metastasis from the testicle to the brain, upon the not infrequent occurrence and the dangers of which authors lay considerable stress, did not take place in his experience. Brain symptoms occurred rather as a complication during the time the parotitis existed or was beginning to decline. Dr. Fink cited several interesting cases of the influence of the mental condition of the mother upon the child in utero. In a paper upon "The Identity or Non-identity of Membranous Croup and Diphtheria," Dr. Gill draws the following conclusions from observations and examination of the subject: 1st, there is no distinction to be made from a microscopic examination of the exudate which would lead to a division of membranous laryngitis into non-diphtheritic and diphtheritic, or simple membranous croup and diphtheritic croup; 2d, there is no distinction, clear and decided, to be made, based on chemical examination of the membranous product; 3d, every clinical manifestation by which a distinction might first appear between diphtheritic and non-diphtheritic membranous laryngitis is unreliable in a differentially diagnostic point of view.

HUMAN AND ANIMAL VARIOLÆ: A Study in Comparative Pathology. By GEORGE FLEMING, F.R.C.V.S.

THE author of this book treats his subject from the point of view of the comparative pathologist. He asserts that in the higher orders, at least, every species of animal has its own distinctive kind of variola, capable of indefinite existence, transmission, or propagation in that species, while its transfer to others is often attended with difficulties, failure, or striking differences in the resulting phenomena. Refuting the idea of the identity of human variola and vaccinia, the author avails himself largely of the researches and experiments of the committee appointed by the Society of Medical Sciences, of Lyons, to investigate this and kindred subjects.

HOW WE FED THE BABY TO MAKE HER HEALTHY AND HAPPY. With Health Hints. By C. E. PAGE, M.D.

THIS is quite a commendable little treatise upon the dietetic and hygienic management of infants. Brought up in strict accordance with the author's views, his little girl, so the fond father tells us, has attained the very acme of infantile perfection. The book is worthy of the perusal of practitioners and parents.

TRANSACTIONS OF THE ELEVENTH ANNUAL SESSION OF THE MEDICAL SOCIETY OF VIRGINIA, held in Danville, October 19, 20, and 21, 1880. Richmond: J. W. Ferguson & Son. 1880.

THE session was opened with the president, Dr. Henry Latham, of Lynchburg, in the chair. In his address to the convention, he severely criticised the attitude of the State toward the medical profession, the low estimate the commonwealth placed upon the services of the latter, as evinced by certain acts in regard to professional compensation, and the criminal inadequacy of the laws upon the subject of coroners. He alluded with pleasure to the fact that the two medical colleges of Virginia had adopted a three years' course of medical study, pointed out the advantages of a knowledge of medical jurisprudence, and concluded with remarks upon the importance of medical societies. The papers presented were not numerous; no surgical reports were submitted. In his article on "New Remedies," Dr. Cullen stated that his experience led him to regard viburnum prunifolium as "a real remedy in threatened abortion or flooding after it." He has also obtained good results in functional cardiac disease through the administration of cereus bonplandii. Dr. Dabney read a paper upon "The Practical Bearing of Recent Advances in Cerebral Localization and Cerebral Thermometry." The next convention will be held at Warrentown.

# Reports of Societies.

## ILLINOIS STATE MEDICAL SOCIETY.

*Thirty-first Annual Meeting, held at Chicago, Ill., May 17, 18, and 19, 1881.*

(Special Report to THE MEDICAL RECORD).

TUESDAY, MAY 17TH.—FIRST DAY.

DR. GEORGE WHEELER JONES, OF DANVILLE, PRESIDENT, IN THE CHAIR.

THE PRESIDENT'S ADDRESS

dealt with the state of indifference in the profession of the southern part of Illinois, in regard to the State Medical Society. It referred to medical legislation, and advised the appointment of a committee to look after it. It alluded to insufficiency of training and predominance of quackery in the present age, and commended higher education. The

REPORT ON PRACTICAL MEDICINE

was read by DR. E. P. COOK, of Mendota. He gave information received from all parts of the State on the subject of epidemics. Typho-malarial fever prevailed in the latter part of 1880. The last six months had been exceptional in the prevalence of rare diseases, and in increased mortality. Zymotic diseases had been on the increase since October, 1880. The southern part of the State had been more favored than the rest, enjoying as it did last winter the climate common to a more northern latitude.

Rubeola of a mild character prevailed in almost every district. Cerebro-spinal meningitis had been observed first in January, some cases complicating measles. Variola was present in the northern part, especially in Chicago, and vaccination had been received with unusual favor by the people. Variola had been traced back to Chicago from most outside districts. Pneumonia appeared in various counties, and an epidemic of dysentery had been observed in De Witt County. Pertussis prevailed in an epidemic form over the State, causing many deaths; vaccination had mitigated the disease in some cases. Winter cholera, properly a form of gastro-enteritis, had first made its appearance in January; in some cases it resembled cholera morbus, lasted one to two weeks, and was unaccompanied by fever. It was probably specific. Anodynes, astringents, and antiseptics constituted the treatment. A few cases of trichinosis were on record. An increase in the mortality from most diseases had occurred in the cities and villages situated along the Illinois canal and river to the Mississippi, and had been referred to the sewerage of Chicago, some of which follows that course. This had become the leading sanitary topic in the State outside of Chicago.

DR. WHITMIRE related the particulars of an epidemic of malignant diphtheria, which originated

among visitors to the corpse of a patient who had died of the disease, in July, 1880. Eighteen per cent. of the cases died. This was in a low part of the country, on clayey soil, and many of the cellars were in a bad condition. The epidemic ended in January, 1881. Treatment consisted of atomized solutions of carbolic acid and lime-water, laxatives, wine, chloride of iron and chlorate of potassium, quinine, and, in some cases, digitalis; milk diet. Some of the patients were thirty years old, but no death occurred in patients over fifteen years of age.

Dr. R. G. Curtis, of Joliet, said there were twenty or thirty cases of diphtheria all the time in his place, while not one case had been recorded before the opening of the Illinois canal. Scarlatina was also endemic in Joliet. Benzoate of sodium and pilocarpine had been successfully used in a few cases. Croup had co-existed with diphtheria, and did not seem to differ from it in any manner. The mortality from cerebro-spinal meningitis had been from 20 to 67 per cent.

Dr. Charles T. Parks, of Chicago, read the

REPORT ON SURGERY.

Listerism had been almost universally adopted by the younger surgeons, but it had been modified to a great extent, many of the leading operators dispensing with the spray. The most important points in treating wounds was to insure free drainage, close coaptation, and rest. The first was accomplished by the use of rubber tubes, which he thought should not be left longer than seventy-two hours in a wound, on the average. Horsehairs were efficient for capillary drainage. Absorbable tubes, made of chicken bones, softened in strong solutions of hydrochloric acid, seemed an improvement, for they could be used with permanent dressing, and were absorbed as soon as they became useless, or in about eight days. Their only disadvantage was their cost. To insure close coaptation, the catgut ligature was as good as any in tying arteries, but torsion had been successfully used for the purpose of arresting hemorrhage, even from the largest arteries. In his opinion no substance had been so well borne as silkworm-gut ligature. It was less expensive than silver wire, but strong and durable. It was said that catgut was sometimes absorbed too soon, and that soaking it in a solution of one part chromic acid to thirty of glycerine would prevent that disadvantage.

Rest must be secured by splints, pads, or bandages. That insured by Lister's dressing is not the least advantage of that method. Frequent dressing prevents irritation from the discharge, and blood-poisoning, which sometimes follow. He called attention to the high rate of mortality after operations for varicocele, and the severe complications which had followed in many cases. Dr. R. G. Bogue, of Chicago, had introduced a new and more efficient method, which consisted in cutting into the scrotum under the spray, and applying the catgut ligature to one vein at a time, leaving the ligature to be absorbed; no ill result is liable to follow.

Dr. Parks related his experience in the restoration of nerve-trunks, by bringing the two ends of the injured nerves in contact by ligatures. He had tried the operation in two cases, and in both successfully. In one, motion had been lost for eighteen months, and was restored in ten days; sensation returned after four months. He said that the reputation of nerve-stretching in sciatica was now well established, although its pathology was unknown. Experiments on recent subjects to ascertain the strength of the various nerve-trunks of the body had been performed by him for the first time last winter. The brachial nerve sustained 80 pounds, the median, 52; radial, 16; ulnar, 44; facial, 7¼; the great sciatic, 200, and sustained a transverse traction of 236. Some nerve-trunks would elongate two or three inches before breaking.

Dr. Parks had also operated successfully on five cases of hernia, for their radical cure. He had obliterated the peritoneal sac in each of those. One of the patients was exhibited before the meeting.

Dr. William A. Byrd, of Quincy, related a case of supra-orbital neuralgia which had lasted for fifteen years, and which was cured by opening the frontal sinuses, and removing some necrosed bone. He had advantageously dispensed with the tube in tracheotomy, and used wires instead.

Dr. H. Webster Jones, of Chicago, read the report on

OBSTETRICS.

He stated that more uterine diseases exist now than ever. Whether advance in civilization or a closer investigation by gynecologists accounted for this, he could not decide, but he had no praise for those who had claimed such importance for gynecology. He said that two or three ignorant obstetricians kept a gynecologist repairing damages. Although the professors of obstetrics in the various American medical colleges were not surpassed by any in Europe, yet very little, if any, practical experience is acquired in the schools. But few branches necessitate such thorough knowledge as this; for the accoucheur should be able to teach hygiene to his patients, make urine analyses when required, and should even extend his attention to the preparation of the bed of pregnant women. The time at which the membranes should be punctured, the pressure to be exerted on the coccyx, the use of forceps, the support of the perineum, were so many things which required a profound knowledge on the part of the doctor. He commended intra-uterine injections of a two per cent. solution of carbolic acid, twice daily; daily visits for a week, giving douches for subinvolution, and treating any ulceration of the os remaining after seven weeks. The hand he considered the best dilator, and thought the forceps should be seldom used. The last visit should be made four to six weeks after confinement.

Dr. De Laskie Miller approved the recommendations of Dr. Jones in every particular. He said parturition was the most complicated of physiological functions, and taxes the forces of nature to excess. The obstetrician should be skilled in his art. His conduct had greater bearings on obstetrics and on gynecology than most physicians were aware. Of the many causes of rigidity of the os, one was an immature condition of the membranes which had not yet taken on fatty degeneration, as they should at time of delivery. Another was an adhesion of the membrane to the womb. This should be separated by the introduction of the finger within the os and around the membranous sac. If this were overlooked it would be liable to cause laceration of the neck, "a fruitful source of income to the gynecologist." Rupture of the perineum was often dependent on the ignorance of the midwife concerning the relations of the head to the tissues of the mother. In supporting the perineum, compel the flexion of the head to remain until the occiput comes out of the vulva, and prevent a straight expulsion of the head through the perineal tissues.

Dr. J. W. Dora, of Mattoon, read a report on

GYNECOLOGY.

He hoped that false modesty, which was on the wane, would soon allow the practical demonstration of gynecological operations before classes of students. He was aware that much harm had resulted from some dogmatic teaching of the first gynecologists, when applied by the unsuccessful and ignorant. Besides, several highly recommended operations were almost entirely abandoned now. A sort of uterine mania had spread among the profession. In obstructive dysmenorrhœa from flexion, he had made a partial incision of the cervix and dilatation with a good result. He recommended rapid respiration as an anæsthetic in such cases. Carbolized sponge-tents are useful in these. He had used Thomas's curette and the local application of tincture of iodine in metrorrhagia. The curette could be dispensed with in many cases. Gynecology had especially progressed since the discovery of anæsthetics. Injuries following parturition should be immediately repaired, and if a first operation fails, it should be repeated after a convenient time.

Dr. Ellen A. Ingersoll, of Canton, read a paper on the

ETIOLOGY AND TREATMENT OF DYSMENORRHŒA.

The amount of pain in this trouble is in direct ratio to the flow and to the resistance offered by the obstruction. The congestive form is the most common, but it is more amenable to treatment than that depending on flexion. A frequent cause of flexions and versions of the uterus depended on a disproportional increase of the body of the womb in relation to the neck. General atony of the system was more frequently a cause than a result of such diseases, and many uterine troubles depended on hepatic congestion or derangement, attended with constipation and a sallow complexion. The liver was more taxed than any other organ in the elimination of nerve-disintegration, which is thrown out of the system by the liver in the form of cholesterine. She had found good results from the use of mercurials in such cases. She also used tonics, alteratives, viburnum, German camomile, aromatic spirits of ammonia. If the general treatment fails, she employs local means, especially the sponge-tent, some days before the return of the menses. Flexion of the cervix uteri, frequent in early life, often disappears after pregnancy. She considered pessaries best fitted for cases of version and flexion of the body of the uterus.

---

Second Day—Wednesday, May 18th.

Dr. F. C. Hotz, of Chicago, read the report on

OPHTHALMOLOGY AND OIOLOGY.

He commended homatropine to dilate the pupils. Its effect was so rapid and disappeared so quickly that people would submit to it, and be enabled to resume their occupation on the following day. He related a case of otitis of ten years' standing, depending on malarial fever, which was cured by the administration of quinine. He had used boracic acid as a lotion, and potassium iodide internally, without any benefit. He reported in favor of the ear-trumpet, and adversely on the audiphone. He did not believe section of the ocular nerves should replace enucleation of the eyeball, since the former was often a failure.

Dr. W. J. Maynard, of Chicago, read a paper on "Dermatology and Syphilis," which was chiefly devoted to a consideration of

RINGWORM OF THE SCALP,

of which he had observed twenty cases. It was very liable to cause baldness. It was very frequent in children, and more curable if treated early. After a short time the characters of this disease were so lost that its diagnosis was not clear, and it was liable to be called eczema. It was most liable to attack strumous or scrofulous children, and might persist a long time. In mild chronic cases the recovery was sometimes hastened by exciting some local inflammation. A fungus was invariably present at the root of the hair, and the disease was contagious.

The child should have its comb, brush, and bed separate from others, and it should not attend school. The disease was often caught from the lower animals. The incubation of the disease was from seven to fourteen days. Parasiticides meet the first indication. The hair should be cut, at least over and around the diseased spots. Cataplasms softened the scabs, and mercury, the oleate or other less costly preparations of the drug, could be efficiently used; but, in cases of long standing, epilation became necessary, and forceps, made for that purpose, were, perhaps, the best means. Iron, arsenic, cod-liver oil, and iodide of potassium were given internally. A change of air had induced a cure in one of his cases. Relapses were common.

INFLUENCE OF SUBMUCOUS FIBROIDS ON GESTATION AND LABOR.

Dr. C. T. Reber, Shelbyville, reported two cases illustrating the subject. In the first, the fœtus must have died at the fifth month. There were two submucous fibroids in the body of the uterus, one five and the other three inches in length. The delivery occurred at the ninth month, with a good deal of hemorrhage. In the second case the tumor was discovered during labor also, and gave rise to hemorrhage, collapse, and puerperal fever. He considered conception very unfortunate in such cases.

Dr. W. S. Caldwell, of Freeport, read a paper on

ABORTION.

He said that repeated hemorrhage after abortion should lead the physician to explore the cavity of the uterus immediately, and the statements of midwives in regard to the delivery of the placenta were not reliable. In cases of retained placenta he gave ether, dilated the os with the fingers, and removed the membranes. Did not commend the use of placental forceps, nor the administration of ergot.

LARYNGEAL TUMORS.

Dr. E. Fletcher Ingals read an abstract of a paper on this subject, with a report of a dozen cases in his practice. They were most frequent in males, and from the age of twenty to forty years. A mild, chronic catarrhal laryngitis was, in his opinion, the most frequent cause. Some cases depended on syphilis, phthisis, croup, or pharyngitis. The most prominent symptoms were hoarseness, sometimes amounting to aphonia, especially if the tumor grew on one of the vocal cords; tickling, difficulty of deglutition, cough at times of the croupy form, and rarely stridulous respiration, dyspnœa, expectoration of tenacious mucus, which might finally cause suffocation. A moist râle was heard over the larynx.

The laryngoscope was indispensable for a diagnosis. A tumor the size of a pea on or near the vocal cord is a serious obstacle, and must be removed. The removal of malignant growths prolonged life; but, if the tissues were so involved as to suggest a removal of the larynx, he doubted much whether the patient ought to be exposed to sudden death irom the operation, or, at best, to get a very brief relief.

His treatment consisted in the application of astringents to reduce the hyperæmia, removal of the growth in one or two sittings, and hot-water pack for thirty-six hours, to prevent acute inflammation. Local application to laryngeal tumors seemed to provoke them, and were useless at best. Papillar tumors were most common, oftener sessile than pedunculated, and ranged in size from that of a pea to that of a walnut. A case of phthisis had improved after extirpation of a laryngeal tumor, and even gained flesh, but the patient died in the course of a year. He used zinc sulphate, half a drachm to the ounce of water, as a local application; also solutions of silver nitrate, copper sulphate, etc. The removal of tumors in several of his cases had been followed by a complete recovery. Bitter tonics and suitable general treatment had been administered. Cases of malignant tumors had not recovered. Inhalations of tincture of benzoin, of carbolic acid, and of other remedies had been used, in some cases with good results.

Dr. Trusdale, of Rock Island, suggested the local application of carbolic acid to laryngeal tumors, as its inhalation had proved very efficient in the treatment of all forms of laryngitis.

Dr. J. H. Hollister, of Chicago, read a paper on

ABNORMAL THERMAL CONDITIONS IN DISEASES, AND THE MEANS OF CONTROLLING THEM.

He referred the source of animal heat to the oxidation of carbon and the combustion of hydrogen, stating, however, that the vital activities were a necessary factor. Every molecular change produced heat, so that secretions and excretions are both attended with the production of heat; and the latter was an index of vital energy. A part of the food absorbed was also exclusively used for the production of heat. A man in good health generated more heat during digestion than a man suffering with a high fever, for this (*i.e.*, the high fever) was chiefly due to retention of heat. He believed in the existence of vaso-dilator nerves; because secretions will be increased through nerve-stimulus, even without an increase in the blood-supply. The effect of heat-retention in the system was lassitude, anorexia, a derangement of the secretions; paresis of the motor system, diminished capillary circulation attended with congestion and swelling; suspended nutrition, giving rise to necrosis. A high temperature would induce permanent changes, especially in the liver, the organ most influenced thereby. The tissues were stained by the hæmatin of the blood.

A reduction of temperature was obtained in two ways: by lessening the production of heat, and favoring its dissipation. Withdrawal of food, cardiac sedatives, as tartar emetic, veratrum viride, aconite, chloral hydrate, amyl nitrite, and bloodletting, answered the first desideratum; the second was obtained by cold baths, cold packs, cold affusions, etc.

UNION IN INTRACAPSULAR FRACTURES OF THE NECK OF THE FEMUR.

Dr. C. C. Hunt, of Dixon, reported two cases in the adult. The diagnosis could not be made evident. The treatment consisted in strict immobility with longitudinal and lateral extension for six or eight weeks. The foot of the bed had been elevated twelve inches on the injured side and eight on the other. Fourteen pounds were added to the longitudinal extension, and eight pounds to the lateral. The recovery was perfect in both cases.

SPECIALISM IN MEDICINE.

Dr. A. Reeves Jackson, of Chicago, related to what extent this had existed in ancient Egypt, and said that history had repeated itself in our age. The chief causes for such a division of labor in medicine were an increase in professorships, a lack of medical knowledge in the general practitioner, who could not make a practical study of his art in the colleges; or, if a few did, "it was altogether accessory and necessitated an accessory fee." The consciousness of possessing little experience in many cases would lead the young physician to call a specialist in consultation; it was the only proper course, although humiliating. Many found it impossible to avail themselves of all the necessary knowledge, and studied only one subject, while others trusted to luck and did not study at all, well knowing that "nine cases out of ten will get well any way." The college faculties having become aware of this necessity for longer training, some attempted to remedy it "for a consideration." A post-graduate course had thus been established. It was a "repetition of the old story," consisting in lectures and demonstrations, without experimental practice. Precept without example was insufficient, and the various branches taught were only suggestive of a useful treatment.

Specialists were necessary to meet the demand for special skill, and was it not for this the progress of medicine had been arrested. Great men were all specialists, and concentrated energy was the most powerful. Among its evil results, however, were conceit, a proneness to magnify slight ailments, a tendency to originate "men of one idea," and sometimes it would lead to errors in diagnosis. But these were not at all direct results. Men unacquainted with general medicine, or students just out of school, had entered specialism, which here ceased to be specialism to become quackery, sometimes professional quackery. But as no organ carried on the process of life without the participation of all other organs, it was necessary to become well acquainted with all before treating one in particular. Specialists should be welcomed by the profession, as it is the outgrowth of the latter; but they must first be intelligent general practitioners.

Dr. C. W. Earle, of Chicago, read a paper on

EPIDEMIC RÖTHELN.

This had existed in the State of Illinois and the neighboring States, but prevailed especially in Chicago during the past spring. He described the disease as it came under his observation in over one hundred cases. It was contagious—as much so with adults, who never had the disease, as with children—and developed after an incubation of seventeen days. A mild coryza, suffusion of the eyes, enlargement of the glands of the neck, a slight fever, and a characteristic eruption, were invariable symptoms. Prodromal symptoms were not apparent. The temperature remained normal is most cases. Pneumonia complicated a few cases; rheumatism, one or two. Urticaria sometimes appeared, and malarial troubles were liable to be present with it in the Northwest.

Rötheln generally disappeared without desquamation. Hardly any treatment was necessary.

Dr. Roswell Park reported a hundred cases of the same disease (Rötheln) in the orphan asylum. Bronchial complications had been a prominent feature in these. The eruption had a tendency to become confluent in some cases. Mild pharyngitis and laryngitis were present in twenty cases. Sometimes the eruption was discovered on the mucous membrane of the pharynx first. Four cases had severe pneumonia. All recovered under appropriate treatment.

A report of the committee on

MEDICAL LEGISLATION,

sent by Dr. M. A. McClelland of Knoxville, was read by the secretary. Acts to regulate the practice of medicine had often been enacted as a means of protection for the regular practitioners against quacks, yet the latter had often reaped the most benefit from them, exacting their fees in advance when obliged to do so. However, he considered that England surpassed us in the latter element, as the enormous sale of Buchanan's diplomas in that country would prove. Quite a number of clerical gentleman had been connected with the manufacture of bogus diplomas. People were bound to have all they wanted of medicine as well as of theology and politics, and hence the frequent failure of medical legislation. Yet it had always existed in some form. Health officers existed under the Roman empire, and quarantines had always come under State legislation. An effort at regulating the practice of medicine had been attempted in New York, in Massachusetts, in Illinois, and in a few other States; but whenever a lawsuit was instituted, it would be considered as a persecution by attorneys, and failed from securing the application of the law. The legislature had been so unfavorable to the medical profession in this State as to admit the claims of the physician only as sixth in the list after the death of the patient.

The next paper was by Dr. H. Gradle, of Chicago, on the

INFECTIOUSNESS OF TUBERCULOSIS.

It develops after an incubation of two to four weeks, in rabbits. Inoculation had been used as a test in clearing the diagnosis of that disease in man; and fungous arthritis had been proven to be a local process of that disease, through that means. Scrofula belonged in that class, as tubercles had been obtained from scrofulous ulcers. In cases where tubercles were produced by mechanical irritation only, they were not specific, and could not reinoculate the disease. Nothing but true tuberculosis would reproduce it. By experiments, it was found that tubercles circulate in the blood of some tubercular patients. The frequency of contagion through the respiratory organs would partly explain the frequency of the disease in the lungs, and the bowels would be more likely to receive the contagion through contaminated milk. Atomized tubercular matter was a ready means of communicating it to dogs. A peculiar micro-organism, which had been repeatedly found in tuberculosis, seemed most likely to be the cause of it, as it reproduced the disease after all other matter had been excluded. In fungous arthritis and other localizations of the disease, tubercles must have been present somewhere in the body previous to the local injury.

Dr. E. F. Ingals said that it was evident to him that tuberculosis was infectious, although he could not say whether the contagium was a micro-organism, and he thought it might take the coming decade to decide this question.

USE AND ABUSES OF ALCOHOL.

Dr. E. Ingals had corresponded with all the leading members of the society regarding the use of alcohol. Most of them replied that it was a narcotic poison, a sedative, and a paralyzer. That it led to diseases of the nervous and of the locomotor system, and was prone to affect the mind. It was anæsthetic to some extent. Many abnormal processes would follow its abuse in man.

Dr. Ingals said that, in his experience, alcohol in appropriate doses was a stimulating tonic of great efficiency. It was unsurpassed by any other remedy in collapse and other diseased conditions. From time immemorial, wine had been considered one of the good things of earth. But alcohol should not be used in health, and physicians should discountenance its use by their example as by their precepts. Yet, as a remedy, it should not be discarded because abused.

---

THURSDAY, MAY 19TH—THIRD DAY.

THE USE OF CHIAN TURPENTINE IN CANCER.

Dr. E. Andrews, of Chicago, had made a series of investigations on this subject, which he reported before the society. The first samples procured were a balsamic mixture, partly composed of balsam of fir. Later he procured the genuine article, and used it with about the same results in one hundred cases, together with surgical measures. Many of these cases passed from his observation. Sulphur had been used at the same time. A case of epithelioma of the lip had been benefited by the use of sulphur alone during three months. Most patients affected with cancer were in the habit of reporting favorably after using any new remedy for a short time. In his opinion, neither Chian turpentine, nor any balsam was of any apparent benefit in cancer. Perhaps it was good in some forms of benign tumors.

Dr P. S. Hayes read a paper on

EPILATION BY ELECTROLYSIS.

He described the process, and was confident that this was the quickest, safest, and most certain of depilatories. It had been successfully used in ectropion by Mitchell, of St. Louis, in 1875, and by Dr. G. H. Parks, of New York, in 1879. A suitable battery, with forceps and needles, are all that is necessary. A strong current is preferable. The needle forming the negative pole, its larger end was introduced into the papilla, along the hair follicle, and the current connected by placing the positive electrode near the spot, or letting the patient hold it. The hair was held by the forceps while introducing the needle, and it was now easily extracted; the pain was blunted by the electrolysis. This process is especially applicable to moles. The operation seldom needs to be repeated.

Dr. Roswell Park had made careful dissections of *the sheaths of the palmar tendons*, and described their arrangement and its bearing on surgical operations. He advised the use of anæsthetics, and a careful dissection of the tissues in opening deep-seated abscesses about the hand or wrist, in order to avoid permanent injury.

THE BASIS OF LISTER'S THEORY.

DR. TRUSDALE said that Lister had taken the profession by storm with his germicide theory, but that he, as well as many other surgeons, regarded carbolic acid as one of the best antiphlogistics, and thus accounted for the excellent results of its use as a lotion or as a spray. There were many antiseptics just as good as carbolic acid to destroy low organizations, yet none of them could replace it in surgical operations; nay, some were injurious. Carbolic acid acted as a powerful stimulant to the nerves, thereby constricting capillaries, retarding vital process, and suspending it if used in strong solutions. It was also anæsthetic, even when producing the mummification of a part. The spray was especially useful in applying carbolic acid locally in a very diluted form, best suited to the internal organs. Its range of usefulness was almost unlimited. He had used it in burns and scalds with a very good result.

DR. J. P. JOHNSON, of Peoria, had used preparations of phenol with as good results as carbolic acid. He had used the latter locally in abscesses of the vulva, penetrating ulcer of the cornea, in ulceration of the os, and to the inside of the uterus, with excellent results. He applied it with a stick shaped for that purpose, and dipped in liquid carbolic acid. The absence of pain gave this the advantage over all other escharotics. He called particular attention to the preservative power of carbolic acid when used to keep specimens, and thought it acted on the same principle on the living tissue.

The officers elected for the ensuing year were:

*President*—Robert Boal, of Peoria.

*Vice-Presidents*—A. T. Dora, of Tolono; Ellen A. Ingersoll, Canton.

*Treasurer*—J. H. Hollister, Chicago.

*Secretary*—S. J. Jones. Chicago.

*Assistant Secretary*—W. A. Byrd, Quincy.

Next place of meeting, Quincy.

## NEW YORK SURGICAL SOCIETY.

*Stated Meeting, March* 22, 1881.

DR. H. B. SANDS, PRESIDENT, IN THE CHAIR.

NASO-PHARYNGEAL POLYPUS.

DR. GEO. A. PETERS presented a patient with the following history. He was seventeen years of age, and was admitted to St. Luke's Hospital, January 24, 1881. On admission a tumor was found which occupied the posterior nares, projected forward and appeared externally at the left meatus, and filled a large portion of the right nostril. It was elastic to the touch, and, on looking through the mouth, was seen pushing the uvula downward and forward, and encroaching somewhat upon the throat. The tumor appeared eighteen months before his admission, during which time he had been seen by several specialists and physicians, and one had succeeded in removing a small portion of the growth with the wire loop. It was recognized as a naso-pharyngeal polypus, and an operation for its removal was advised and accepted. After performing Dr. Cheever's and one or two other osteo-plastic operations upon the cadaver, for the purpose of ascertaining which would give the best opportunity for removing the tumor, Dr. Peters finally reached the conclusion that the operation recommended by Maisoneuve, and practised by Dr. Sands in a case which he had reported, was best adapted to the case. The patient was etherized in the usual way, and, as a preliminary step in the operation, Dr. Peters introduced, through an opening made through the crico-thyroid space, an ordinary tracheal canula, to which was attached an elastic tube with a funnel at the other end, through which the ether was administered during the subsequent steps of the operation. A large piece of sponge, with a stout string attached, was then crowded into the posterior fauces, shutting out the flow of blood from the larynx and œsophagus. His reason for using the sponge was partly because of the results of his experience with it in like operations, and partly from the fact that the only Trendelenberg's tube he had at hand was one made for the adult larynx, and was too large for this case. The plan he adopted was perfectly satisfactory. Not a drop of blood found its way either into the air-passages or stomach. The knife was now introduced just below the inner canthus upon the left side, cutting through all the tissues to the bone on the line of junction between the cheek and the nose, passing around the left ala into the opening of the nostril, thence along the junction of the skin and mucous membrane to the middle line, and along the latter to the free margin of the upper lip, the latter being completely divided. This flap was dissected up and the bone beneath fully exposed. With a Langenbeck's button-pointed saw he notched moderately the surface of the maxillary bone on a line corresponding with the floor of the antrum. He then split the mucous membrane upon the hard palate, detached the soft palate laterally; instead of dividing it through the centre, as is usually done, he made his incision upon one side, so that the curtain of the palate fell down entire. He then removed the left central incisor tooth, and with bayonet forceps —one blade in the nose and the other in the mouth —crushed the bone. The forceps were then introduced into the groove made by the saw, the bone detached, and afterward wrenched out with the lever forceps. This gave abundant room for the removal of the tumor, which was extensively attached to the basilar process of the occipital and to the sphenoid bones, and it was removed with scissors, scrapers, and the fingers. It was very vascular, and the hemorrhage was profuse. The tumor was removed with considerable difficulty. No vessels required ligation. The flaps were secured in position with fine sutures, and one twisted suture at the edge of the lip. The recovery was rapid and without complication, and the result was excellent.

DR. SATTERTHWAITE, after examination, pronounced the tumor to be a fibroma, although a portion pinched off from the part projecting from the nostril, before the operation, presented under the microscope the appearance of a "small-celled sarcoma and very vascular." This was probably owing to the inflammation following the application of the wire loop which had been used by a surgeon to remove the projecting portion of the tumor before the patient came under the care of Dr. Peters.

DR. PETERS remarked that when performing the different operations on the cadaver, he was surprised to find how little room Dr. Cheever's gave.

DR. WEIR remarked that while witnessing Dr. Peters' performance of this operation, he was struck by the unnecessary amount of room offered by Maisoneuve's section of the jaw. Since that time he had experimented on the cadaver, and had succeeded in obtaining sufficient room by cutting away the jaw along with the roof of the mouth, as in the plan usually followed, but preserving the alveolar process and

teeth posterior to the first cuspid tooth. Less deformity would result by such a procedure, and space enough by this method would be afforded for all the required surgical manipulations.

### THE MECHANISM OF COLLES' FRACTURE.

Dr. Frank H. Hamilton then spoke on the above subject, substantially as follows:

It is my opinion that the classical fracture of the lower end of the radius, known as Colles' fracture, is the product of three causes. By the classical fracture I understand that which occurs, and is the most common, usually about three-fourths of an inch from the lower end of the radius, ranging from one-fourth to one inch, but averaging three-fourths of an inch. In rare and exceptional cases, the fracture is still lower, quite at the epiphyseal line.

The three causes which operate in the production of the classical fracture, are:

*First.*—Impact, as synonymous with concussion, upon the lower end of the radius. I mean by it that in the fall upon the palm of the hand, the lower end of the radius is caught between two forces: first, the impulse or weight; second, resistance of the ground. I assign this as the principal cause of this fracture.

*Second.*—Avulsion, or *par arrachement*, or the tearing off effect through the action of the anterior ligament of the carpus; especially through the action of two very strong fasciculi of this ligament. It will be seen farther on that I ascribe to this force a greater role in the production of a certain class of fractures, but which do not belong to the classical form now under consideration.

*Third.*—Muscular action has something to do, if not directly, with the production of the fracture, it indirectly does in the steadying of the wrist, and with its ultimate sequences, namely, impaction, etc.

Dr. Hamilton then gave a brief *résumé* of the literature of the subject, and theories set forth by the different writers. He said: So far as I know, Pouteau was the first to describe accurately the fracture, an account of which is found in his memoirs, published in 1783. He ascribed the fracture in question solely to muscular action.

According to Malgaigne, about the year 1820, Dupuytren having also described this fracture in detail, declared that it was due wholly to concussion, or impact, the force of the fall being conveyed from the palm of the hand through the carpal bones indirectly to the lower end of the radius.

To this day a large majority of surgeons who have written upon this subject have accepted this theory as being satisfactory, and as alone explaining the phenomena which are usually present.

In 1834, M. Bouchet, in a thesis, declared that in his attempt to produce dislocation upon the cadaver he had always produced a fracture; and in 1842 M. Voillemier stated that he had seen two fractures of the lower end of the radius caused by avulsion alone. In one case the patient had fallen upon the extremities of his fingers, and in the second case it had been caused by bending the hand forcibly back, the injury being inflicted by a companion. And Malgaigne, in 1855, in alluding to these cases, remarks that he would not be surprised if it should be found that a good number of these fractures were produced in this way.

In 1860–61, M. Oneseme Lecompte published in the *Archiv. Générales des Medicin* an elaborate paper on the subject of fracture of the lower end of the radius, which can be found in the numbers for December, 1860, and for January and February, 1861, and in which, after a careful description of the ligaments, anterior and posterior, with a study of the physiology and the pathology of this accident, he announces that the fracture is *always* produced by *arrachement*, and that even Barton's fracture, so-called—namely, a chipping off of the posterior margin of the lower end of the radius—was produced, at least primarily, by the same cause. He did not admit that anything was due to muscular action or to impact.

M. Tillaux in his "Anatomie Topographique," published in 1877, says: "I agree with Lecompte, that the classical fracture of the lower end of the radius is always produced by *arrachement*."

In 1878, Dr. Pilcher read before the Academy of Medicine, in this city, a paper upon this subject, in which he ascribes the fracture also to the same cause. He also, in a late paper, refers to Duplay as having entertained the same opinion.

I have omitted to refer to several other authors who have written upon this subject, such as, Jarjavay, Diday, Hoel, Nélaton, Colles, Robert W. Smith, and others, and for the reason that they have contributed nothing specially in the elucidation of the points now under discussion. Colles, whose views were first given to the public in the *Edinburgh Medical and Surgical Journal*, in 1814, had made *only* some clinical observations, and placed the seat of the fracture at one and one-half inch above the end of the radius, an error into which clinical observation would be very likely to lead him.

Robert W. Smith wrote in 1847.

It is against each of these exclusive theories that I address myself.

That it is exclusively due to muscular action is a view which has long since been abandoned. That it is not entirely due to impact is equally improbable in my judgment, although it is the opinion which has been entertained by the great majority of surgeons up to the present time.

Before proceeding further, I will first call your attention to the measurements made by Robert W. Smith, of *twenty* museum specimens, the measurements being made to determine the length of the lower fragment, and upon the palmar surface. Of these twenty specimens, in *two* examples the line of the fracture upon the palmar surface is one quarter of an inch from the nearest point of the articulation. In *two*, it is one-half an inch; in *two*, five-eighths of an inch; in *ten*, three-quarters of an inch; and in *four*, it is one inch. And an examination of the illustrations of most of these specimens found in his book confirm these measurements made so carefully by him. It will be observed that Smith also attempts, by these specimens, to refute the argument of Voillemier, who claimed that there was usually impaction. He made a longitudinal section antero-posteriorly of the lower end of the bones, by which he was able to show that a large amount of apparent impaction was due to the presence of the overlying callus. But he failed entirely to show that a portion of this dense lamellated tissue, which was seen penetrating toward the lower end of the radius, did not indicate a certain amount of impaction. Indeed, the inclined position assumed in nearly all these fractures illustrated in Smith's drawings sufficiently show that a degree of impaction was inevitable.

I wish next to call your attention to these specimens which are before me, and first to those from the New York Hospital Museum. In this collection the fracture was produced by impact, and in nine it

traversed the entire diameter of the bone from side to side. They are twelve in number and I will give you the summary.

Length of lower fragment from the lowest point on the anterior face: Less than one-quarter of an inch, 1; one-quarter of an inch and over, 2; three-eighths of an inch and over, 2; one-half an inch and over, 7. In all, except one specimen, the fracture was oblique from below up and back, so that the lower fragment was the longest posteriorly.

I will now present specimens of

FRACTURES CAUSED BY AVULSION ON THE CADAVER.

First, those produced by *forced dorsal flexion.* Of these there were *five.*

No. 1. Rupture of anterior carpal ligament at two points, and nearly transverse fracture at the base of the styloid apophysis of the radius. Adult male bone. Right radius.

No. 2. The left radius of the same body, broken in precisely the same manner.

No. 3. Left radius of adult male, broken in a manner similar to Nos. 1 and 2, but with a little more obliquity, involving nearly the whole transverse diameter of the bone, and terminating in the joint just at the ulnar margin.

No. 4. Left radius of an adult male; the fracture being nearly an exact counterpart of No. 3.

No. 5. Left radius of a woman. Transverse fracture, involving a thin plate of the anterior margin of the lower end of the radius, and terminating through its whole length in the joint. The fracture includes only that portion of the bone to which the anterior ligament is attached. The third insertion of the ligament, which I took the liberty of naming Pilcher's ligament, is intact—the oblique fasciculus of the anterior ligament. I think he was the first to demonstrate its full value in the distortion which exists after the fracture has occurred.

I have next to present specimens of fracture produced by *forced palmar flexion;* they are *three* in number. I do not know that the argument has been fully expounded upon this point, but I suppose it has been intended to say that, when the bone breaks by forced flexion, pressure being made upon the back of the wrist, the fracture is due to the same mechanism—the action of the carpal ligaments.

In the *first* specimen the bone is broken almost precisely on the line of the epiphysis, at from one-eighth to one-fourth of an inch from the lower end. In all these instances the subject was not under thirty years of age, and as the epiphyseal junction is united firmly at the age of twenty, we cannot suppose it is merely an epiphyseal separation; and besides, the character of the lesion shows that it is not.

In the next specimen the fracture, produced also by forced palmar flexion, is still nearer to the margin; so near that I was in doubt whether it was not the ligament which had given way, but upon examination I ascertained that it was just within the epiphyseal line, probably not more than two millimeters of the lower end of the radius being carried off. It also is exactly transverse.

Here is the third specimen belonging to this group, in which the fracture was produced by forced palmar flexion, and it took place a little higher up, about one-fourth of an inch from the lower end of the bone, and exactly transverse. Apparently the fracture is not complete antero-posteriorly.

I have also to mention that Dr. Ferguson brought me a specimen recently which he had produced by avulsion, and in which the hand was thrown *back* with a great deal of force, and the bone was broken at the classical point one-half or three-fourths of an inch above the lower end of the radius. I supposed the specimen was in this collection, but it is not here.

I should add to those presented, as illustrating the first group, a fracture caused by a fall upon the palm of the hand, two cases of my own; one of which is figured in the last edition of my work on "Fractures and Dislocations," Figs. 91 and 92. In both cases the fracture was produced by falls, and it was from one-half to three-fourths of an inch from the lower end of the radius; in one nearly transverse, in the other very oblique, before, back, and upward.

I have next to call your attention to the marked obliquity seen in these Museum specimens, and also illustrated by Robert W. Smith's specimens. You will see that in a majority of them—exceptions exist—the line of fracture is from before, back and upward. I am prepared to say, therefore, upon this point, so far as I can judge, that obliquity upward and backward is rather the rule than the exception when the fracture is produced by impact. That has not been so positively stated by other writers. According to my later observations, however, the rule is almost universal. At all events, we may say that, in the great majority of cases, there is obliquity from before, backward and upward where there is impact; but if there is lateral obliquity, as there is occasionally, it is very unlike that seen in those cases in which the styloid apophysis is broken off from the lower end of the radius by avulsion; it is a line running up along the axis of the bone, forming a clean, sharp edge all the way up; but when produced by *arrachement,* it is very nearly transverse, and ordinarily presents a uniformly serrated appearance. There is comminution, in a certain number of cases, of the lower fragment. There is a question as to what it is that produces this comminution of the lower fragment, and I have no doubt that Dr. Pilcher would be correct if he would say that in the majority of cases it is due to impact; but if he says *all* cases, I believe he is in error. I believe that impaction occurs to a limited extent in the majority of cases; and, theoretically, I assume that it should be so, 1st, because there is impact; 2d, because there is strong muscular action; and 3d, because the fragment is tilted back, and therefore, unless the bone is elongated, it must be impacted to a certain extent. But the fact of the existence of impaction to this extent cannot be used against *arrachement,* as Dr. Pilcher thinks it may be. It is much easier for me to assume that comminution of the lower fragment is due to impact than it is to believe that it is due to *arrachement.*

But I wish to address the society chiefly upon the point whether Dr. Pilcher, Le Compte, Tillaux, Duplay, and others, are correct in assuming that the classical fracture is *always* due to *arrachement,* or whether I am correct in assuming that it is due to the action of *three* operating forces.

But I have not given full credit to *arrachement.* I think it solely responsible for the production of that fracture in which the styloid apophysis of the radius is broken off at its base nearly at a right angle with the axis of the bone.

If the force of the impact is sufficient to break the lower end of the radius, and does not cease there, it extends and expends itself upon the oblique fasciculus of the anterior ligament, which terminates in the styloid process of the ulna, and tears it off. And this is explained by the especially broad and strong

insertion of the anterior carpal ligament into the crest of the anterior apophysis of the radius along its outer or radial margin. Also, it explains how *arrachement* is solely responsible for the result when the specimen shows tearing off only of the anterior margin of the lower end of the radius, as seen in one of my specimens; and also when the fracture is exactly at the epiphyseal junction, as seen in another of my specimens.

Dr. Post asked whether any member had seen deep impaction in a recent case of Colles' fracture.

Dr. Hamilton replied that Fig. 92 in the last edition of his work on "Fractures and Dislocations" illustrated a case of that kind. He did not suppose that impaction would occur to a degree which would make it difficult to overcome by traction when there was no muscular action.

Dr. L. A. Stimson, referring to Dr. Hamilton's statement that he had understood from Dr. Pilcher that Duplay accepted the exclusive theory of avulsion, said that in a surgery written by Folin and Duplay the two kinds of mechanism of Colles' fracture were mentioned distinctly—first, that by avulsion, and second, that by crushing, so clearly described by Dr. Hamilton.

It seemed to him, with reference to avulsion, that it was necessary to bear one point in mind, as far as it is a factor in the ordinary production of this injury. He was inclined to think that the opinions of surgeons had been largely influenced, and perhaps too much so, by results obtained upon the cadaver. Dorsal flexion to produce avulsion must be carried beyond a right angle, and, as a matter of fact, when a man falls upon his hand, it is very exceptional to have the hand flexed beyond a right angle. By looking at one's own hand, he thought it was apparent that the heel of the thumb is not to the outside of the axis of the shaft of the radius; in other words, it is not in a position to exercise any leverage. Any force which tears off the anterior portion of the radius must be exerted upon a point on the posterior side of the fulcrum. That point does not exist in the ordinary fall upon the heel of the thumb. It exists only in a fall in which the pressure acts upon the metacarpal bones. The motion of the hand upon the wrist takes place not entirely between the radius and the carpal bones, which are in immediate contact with it, but rather between the first and second rows of bones of the carpus. It is impossible to throw one's hand far enough back to give a line of the carpal bones behind the posterior border of the radius. Therefore he thought the mechanism of crushing is usually more frequent than that of avulsion. Unquestionably, avulsion does occur. This specimen which I present, produced by an ordinary fall, shows quite complete comminution, but I think there is no trace of avulsion.

Dr. Weir thought that the antagonistic position of Dr. Hamilton and of the believers in the theory of avulsion as a cause of fracture of the lower end of the radius resembled not a little that of the disputative knights in the fable of the gold and silver shield. Both parties were probably right in the question of the fracture. The specimens presented to-night corroborated the fact first enunciated by Foucher in 1852, and subsequently developed at length by Lecomte, and of late revived by Pilcher, who, in his second paper, modifying the views of his first, acknowledged the labors of his French predecessor. From these and other sources it is proven that avulsion by means of the anterior ligament is the cause of the transverse fracture of this portion of the radius. He himself believed that avulsion so acts when the hand is in a position of extreme or anatomical extension, and that the further changes in the radius were produced by the impact of the carpus against the posterior portion of the bone above. But does avulsion act when the hand is merely in a condition of physiological or ordinary extension; and again, in a fall producing the fracture, is the hand anatomically extended? To answer the first question, he had made a few experiments on the cadaver in subjects between twenty and fifty years of age, and he presented for inspection of the society two upper extremities wherein the force had been applied, as Lecomte suggested, to the humerus, with the hand fixed in a position of physiological or moderate extension, and it will be seen that a fracture exists in the anterior aspect of the radius, beginning half an inch from the joint, and that on its posterior margin the line of fracture runs obliquely upward and outward from a point half an inch from the joint to more than an inch at the ulnar aspect of the bone. No comminution of the lower fragment, however, took place. In another specimen a strongly comminuted fracture exists, with characteristic posterior deformity.

To further test the effect of the impaction theory —that is to say, the effect of the weight of the body on the hand, directly or *vice versa*—in the one specimen the anterior ligament was divided, in the other subcutaneously, with the effect, with the hand in anatomical or forced extension, of giving rise to a slightly comminuted fracture of the posterior ligament only of the radius, running up nearly an inch on that side; and in the other specimen, where the muscle had been dissected up, the ligament was exposed and divided throughout, and then the force of impact was applied, with the hand in extreme anatomical extension, producing no injury to the radies, but comminuting the semilunar bone.

As to whether, in the ordinary falls, the hand is physiologically or anatomically extended it is difficult to determine, though the presumption is more in favor of the latter, and several experiments of C. Schmit, in his late thesis on the subject of the fractures, seems to prove this. Schmit rendered immovable the elbows in a cadaver, and allowed the body to fall forward. The hand encountered the ground, became anatomically extended, and in certain instances rested against the dorsum of the forearm, producing a fracture. It had been asserted that direct force could not be applied to the radies by means of the carpus in extreme extension, and that the pillars of the first arch—*i.e.*, the scaphoid and the piciform bones—did not, in such a position, touch the ground. A repetition of Cruse's experiments, made this afternoon, showed that with ink applied to these points, contact with a sheet of paper could be made in more than half the trials essayed, bringing, however, the piciform down more readily than the scaphoid. From these experiments, it seemed clear to him that avulsion and direct pressure both combined to produce this fracture, when coexisting in the order of time mentioned.

It was observed, in the production of the fracture experimentally, that it was more difficult to accomplish it in the young subject than in the old. Schmit has tested this point by the dynamometer. By avulsion—that is, by forcibly extending the hand or the forearm in adults from eighteen to fifty years of age —an average force of fifty kilogrammes was required. In adults beyond sixty years an average force of thirty kilogrammes was demanded. By direct pres-

sure (Nélaton's method), the force, even in old people, varied from ninety to one hundred kilogrammes. This is the scientific expression of the clinical fact, long in our possession, that fractures of the lower end of the radius are more common in elderly persons.

THE PRESIDENT drew attention to the fact that the experiments made by Dr. Hamilton, and the specimens shown, seemed to be unlike those which are in the possession of Dr. Pilcher. So far as Dr. Hamilton's specimens showed, there is a very great difference between fracture as produced experimentally by forced dorsal flexion and the fractures of the radius contained in the New York Hospital Museum. In looking at these two sets of specimens, Dr. Sands thought that one could hardly avoid the conclusion that the force of avulsion alone failed to account for the production of Colles' fracture. It had been said by Dr. Pilcher that the results of his experiments were different from those obtained by Dr. Hamilton, and that, by the force of avulsion alone, he had usually succeeded in causing fracture of the radius, the situation of which, instead of being close to the articular surface, as in Dr. Hamilton's specimens, was at a considerably higher level, as is generally observed when Colles' fracture occurs in the living subject. Dr. Sands thought it would be desirable to repeat these experiments, in order to determine whether their results were constantly the same, and whether such fractures could be produced as those exhibited by the specimens of Colles' fracture contained in the museum of the hospital.

DR. WEIR suggested that Schmit's experiments might explain the difference – namely, that one used greater force than the other.

THE PRESIDENT said that that might be, but all the specimens exhibited in which the fracture had been experimentally caused by extreme dorsal flexion showed the same kind of lesion, one very unlike Colles' fracture, as now understood.

DR. MASON had seen several specimens of fracture of the same variety as those presented by Dr. Hamilton, which were produced upon the cadaver by different house-surgeons.

DR. HAMILTON, in closing the discussion, said: My argument is based entirely upon the supposition that these fractures, which I have made by avulsion, represent what will be the general result when the force of avulsion is alone applied. It is very easy to simulate avulsion on the cadaver, because it does not require muscular action or impact; and we should get a class of results similar to those which came from falls upon the hand, provided avulsion is the only element of causation to be considered. It is exceedingly difficult, so I believe, to make upon the cadaver such a fracture as that which arises from the fall upon the hand when the physiological forces are in operation; because I maintain that impact, avulsion, and muscular action unite in the production of the classical fracture, the latter being necessary to give tone to the parts so that the forces can be applied more directly to the lower end of the bone. My specimens have been taken without selection, and I had no thought of this difference when they first came into my possession. The idea that the fracture representing avulsion is different from that produced by a fall is a recent one. If Dr. Pilcher's specimens illustrate the same fracture as that produced by a fall upon the hand in the living subject, there is an end of the argument. But the Doctor must not say that if one exception occurs, if he once breaks the radius at the classical point by avulsion, it must therefore be avulsion that causes *all* fractures; because there may be exceptional circumstances, and there may be peculiar harmonies in the fall. I have already cited one specimen which I was unable to present, and in which Dr. Ferguson produced the fracture at the classical point by avulsion upon the cadaver, but it was only as an exception that I mentioned it. The question is, what is the general result of avulsion, and what the general result of a fall upon the hand?

### SUBCUTANEOUS NEUROMA.

DR. A. C. POST presented a subcutaneous neuroma removed from anterior part of the forearm of a man thirty-four years of age. It had existed seven years, and had been the seat of acute pain. The specimen showed filaments of one of the cutaneous nerves projecting from its surface. Since its removal the pain had ceased.

DR. CHAS. K. BRIDDON then presented a specimen of carcinoma of the prostate and rectum, accompanied with a written history.

The society then adjourned.

## Correspondence.

### THE TRADE-MARK MONOPOLY SYSTEM.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR—In reply to a communication from Dr. Bigelow, in your journal for June 25th, in relation to the resolution on patents, trade-marks, and copyrights, now before the American Medical Association, I would like to say a few words. If the aim of the gentleman's communication was in defense of the trade-mark scheme, I would like to ask whether he is aware of the "true inwardness" of the system he is defending. It is a common error to suppose that the so-called "patent medicines" flooding the market are patented. This is rarely the case. The scheme is a trick, unconstitutional in its nature, detrimental to science and the useful arts, and ruinous to legitimate trade.

Well known drugs are mixed together, and a fancy name designed by which to call the compound. This name is registered as a trade-mark; and is the only name by which the article is known; the name is owned by the manufacturer, and used by him to prevent competition. Competition prevented, the owner is enabled to affix an exorbitant price thereon. An immense demand is then created, by advertising the compound to be of marvellous value. This is easily effected, for the publication of reports with regard to the remedy is in the hands of the owner. In the most conservative form of this system, the formulæ are kept secret. The remedy is thus owned body and soul, for the knowledge of its composition, the sale thereof, and the publication of the results of its use are completely in the hands of the manufacturer. *Such is the trade-mark monopoly system.*

There is to be urged against this system, that it is in every respect unscientific and misleading. That it is unconstitutional in its nature, and detrimental to science and the useful arts, can be clearly seen by the following quotation regarding the patent law, against the spirit of which this trade-mark control is obtained:

"Many, and perhaps the great majority of inventors, have incorrect ideas of the nature of a patent

privilege. Starting from false premises, they reason wrongly about various questions that arise, and are never able to comprehend why laws read as they do, and why the courts make certain constructions of the laws. The belief is very generally entertained that inventors have a natural right to their inventions, of the same kind given by the statute, irrespective of the actual passage of the law.

"This is not a fact.

"The right to the exclusive use of an invention is not a natural right—that is, pertaining to men in a state of nature—but when it exists at all it is a civil right, pertains to men under the protection of a civil government.

"An inventor has no right to his invention at common law. He has no right of property in it originally. The right which he derives is a creature of the statute and of grant, and is subject to certain conditions incorporated in the statute and in the grants." There is no absolute or natural right that I, being the original and first inventor to-day, have to prevent you and everybody else from inventing and using to-morrow or next day the same thing."

But the public argue that the promotion of science and the useful arts is of great benefit to society at large, and that such promotion can be attained by granting to inventors the exclusive use of their inventions in exchange for "the giving to the public a full knowledge thereof by means of a proper application for a patent, whereby the public is enabled to practise the invention when the patent expires." The article thus finally becomes public property.

By taking unfair advantage of the trade-mark law, however, manufacturers are enabled to steal a control which does not belong to them by right, hold this control for an unlimited time, so that the article trade-marked never becomes public property, and to prevent the publication of knowledge concerning the remedy, and thereby to lock up science and a useful art from progress.

Scientific indorsement of a scheme of this kind is surely to be decried.

The resolution offered at Richmond was designed to bring up these points for discussion, so that a better system might be adopted compatible with the interests of science and trade.

"*Resolved*, That it is against the spirit of the code of ethics to prescribe a remedy controlled by a patent trade-mark or copyright." This is surely so, for the code distinctly forbids the use of patent medicines in so many words. The spirit of the code is scientific and opposed to any control which shall hinder the free progress of science.

"It shall except, however, a patent upon a process or machinery for manufacture, *provided patent be not used to prevent legitimate competition.*" This is designed to allow trade the protection granted by the patent law, but to prevent a similar advantage from being taken of the patent to lock up the art of pharmacy as in the case of the trade-mark law above described.

"It shall also except the use of a trade-mark used to designate a brand of manufacture, provided the article so marked be accompanied by working formula duly sworn to, and a technical scientific name, under which any one else can manufacture the same." This is to allow the legitimate use of a trade-mark to distinguish a brand of goods. "York Mills," for example, is a trade-mark. It distinguishes a certain brand of linen, but it does not prevent competition in the manufacture of linen. If linen were only known by the name "York Mills," and that name belonged to one manufacturer, a dangerous monopoly would be created. Precisely the same monopoly exists in the case of the trade-mark medicines.

Why the working formula is required, has already been explained.

Finally, the promiscuous classification of new drugs in the category of remedies of the kind described is unfair.

If new drugs are introduced in the same spirit which characterizes the trade-mark medicines, the criticism is sound. Such an introduction is unwarranted; but in a scientific spirit the introduction of new drugs is desirable. It is the duty of the drug trade to supply the demand for drugs, and it is their privilege to create a demand by advertising in a legitimate way. When they attempt to furnish the medical profession with information concerning new drugs, the method chosen is open to criticism, but they certainly have the right to do so. If the information be the best obtainable and credited to its source, this is all that can be asked. It would be well for Dr. Bigelôw to examine this subject more closely before making such sweeping statements. Possibly there are drug-houses in the trade whose motives are pure and whose methods are commendable.

FRANCISCUM.

NEW YORK, July 9th.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July* 10, 1881, *to July* 16, 1881.

SIMONS, JAMES, Lieut. Colonel and Surgeon. Granted leave of absence for one month. S. O. 120, Department of the East, July 20, 1881.

MAUS, L. M., Captain and Asst. Surgeon. Now awaiting orders in Washington, D. C., to report in person to commanding officer, David's Island, N. Y. H., for temporary duty at that post. S. O. 158, A. G. O., July 13, 1881.

COMEGYS, E. T., Captain and Asst. Surgeon. Now awaiting orders at Cincinnati, O., to report in person to commanding officer, Columbus Barracks, O., for temporary duty at that post. S. O. 158, C. S., A. G. O.

GARDINER, J. DE B. W., Captain and Asst. Surgeon. The extension of leave of absence granted him March 14, 1881, from A. G. O., further extended six months. S. O. 157, A. G. O., July 12, 1881.

SHANNON, WILLIAM C., Captain and Asst. Surgeon. Assigned to duty with escort to Ute Commission, from Fort Bridger to the Uintab Agency. On return of Commission to Bridger, to rejoin his station, Fort D. A. Russell. S. O. 62, Department of the Platte, July 6, 1881.

FEMALE PHYSICIANS, says the *Medical and Surgical Reporter*, are all the time gaining points. The Society of Medical Practitioners of St. Petersburg, at their meeting of May 2d, decided to admit medical women to the membership of their Society. In London the number of students in the London School of Medicine for women this past winter reached to the respectable figure of eighty. There are, at the present time, forty-two female medical students in the Paris faculty. Eighteen of them are English, eleven French, ten Russian, and three Americans.

# Medical Items and News.

YELLOW FEVER APPEARING.—Acting Assistant Surgeon Blount, of the Marine Hospital Service, announces that two cases of yellow fever have been brought to Pensacola, Florida, in the ship Emma Payzant. Since these cases appeared, five others have developed on the same vessel. The disease has not, however, reached the city.

MEDICAL ANALYSIS OF THE PRESIDENT'S CASE.—The following tabular statement shows the variations of the pulse, temperature, and respiration in President Garfield, from July 3d to date of going to press:

| *Date.* | *Time.* | *Pulse.* | *Temperature.* | *Respiration.* |
|---|---|---|---|---|
| July 3 | 10.30 P.M. | 120 | 100.0 | 20 |
| July 4 | 12.30 A.M. | 112 | 99.8 | 20 |
| July 4 | 8.15 A.M. | 108 | 99.4 | 19 |
| July 4 | 12 30 P.M. | 110 | 100.0 | 24 |
| July 4 | 7.45 P.M. | 126 | 101.9 | 24 |
| July 4 | 10 00 P.M. | 124 | 101 0 | 24 |
| July 5 | 8.30 A.M. | 114 | 100.5 | 24 |
| July 5 | 12.30 P.M. | 110 | 101.0 | 24 |
| July 5 | 8.30 P.M. | 106 | 100.9 | 24 |
| July 6 | 8.30 A.M. | 98 | 98 9 | 23 |
| July 6 | 12.30 P.M. | 100 | 99.7 | 23 |
| July 6 | 8.30 P.M. | 104 | 10 0.6 | 23 |
| July 7 | 9.15 A.M. | 94 | 99.1 | 23 |
| July 7 | 1.00 P.M. | 100 | 100.8 | 23 |
| July 7 | 8.00 P.M. | 106 | 100.3 | 23 |
| July 8 | 8.15 A.M. | 96 | 99.2 | 23 |
| July 8 | 12.30 P.M. | 108 | 101.4 | 24 |
| July 8 | 8.00 P.M. | 108 | 101.3 | 24 |
| July 9 | 8.30 P.M. | 100 | 99.4 | 24 |
| July 9 | 1.00 P.M. | 104 | 101.2 | 22 |
| July 9 | 7.15 P.M. | 108 | 101.9 | 24 |
| July 10 | 10.00 A.M. | 106 | 100.0 | 23 |
| July 10 | 1.00 P.M. | 102 | 100.5 | 22 |
| July 10 | 7.00 P.M. | 108 | 101.9 | 24 |
| July 11 | 8.00 A.M. | 98 | 99.2 | 24 |
| July 11 | 1.00 P.M. | 103 | 99.8 | 24 |
| July 12 | 8.00 A.M. | 96 | 98.6 | 22 |
| July 12 | 7.00 P.M. | 104 | 102.4 | 24 |
| July 13 | 7.30 A.M. | 93 | 98.5 | 20 |

ASSISTANT SANITARY INSPECTORS.—The corps of fifty Sanitary Inspectors annually appointed by the City Board of Health began work last week.

GRISCOM'S FAST.—John Griscom is said to have completed his forty-five days' fast in Chicago. Little attention was paid to his experiment, if such it was. The scientific results from the study of his case remain to be announced.

CHLORAL HYDRATE AND GLYCERINE, IN DIPHTHERIA.—A solution of fifteen to thirty parts of chloral hydrate in one hundred parts of glycerine is the latest German remedy for diphtheria. The solution is to be applied locally every two hours, with a soft camel's-hair brush. Korn, who recommends this method of treatment, has used it with gratifying results for the past fifteen years.

EXCURSIONS FOR SICK CHILDREN.—The Floating Hospital of St. John's Guild has been put in thorough condition. The first trip of the barge was made on Tuesday, the 5th inst., leaving the Guion pier, foot of King street, North River, at a quarter past 8 A.M., and foot of Fifth street, East River, one hour later. Trips are to be made regularly through the season from the same points on Tuesday, Thursday, and Saturday of each week. Tickets may be obtained at all of the dispensaries and of physicians. The Floating Hospital is to be supplemented this summer by the Seaside Nursery, and the work of saving the sick babies will be prosecuted as diligently as means for the purpose are given. Donations for this work are urgently requested, and may be sent to William H. Guion, treasurer, No. 8 University place.

A NEW EXHILARANT.—M. Luton discovered by accident the effects of the following exhilarating mixture: Tincture of ergot of rye, five grammes (gr. 75); solution of phosphate of sodium (ten per cent.), fifteen grammes (℥ ss.). Mix in a quarter of a glass of sweetened water, and give at one dose on an empty stomach. In very susceptible, excitable people, a condition is produced resembling that following the inhalation of nitrous oxide gas; they laugh excessively, feel slight dizziness on attempting to walk, and in many ways suggest alcoholic intoxication. In those who are more sedate and imperturbable, a condition of mild exhilaration merely is induced; the cutaneous circulation is improved, a feeling of buoyancy and cheerfulness develops itself, and lasts for several hours, the patients being agreeably conscious of mental and physical stimulation. The author has verified these observations in so many cases that they must be considered established. He has found different individuals equally susceptible, but has been able to assure himself that there is always some effect. As might be expected, men are less affected than women; in no case has any unpleasant result been observed. The author feels himself justified in recommending his discovery to the profession, although compelled to do so on a purely empirical basis, having arrived at no satisfactory explanation of the action of the mixture. He especially advises its use in cases of melancholia, hysteria, chlorosis, and the various conditions in which languor and depression of spirits are present. The patients to whom he has given it were sufficiently convinced of the efficacy of his prescription to ask for its repetition, assuring him of the benefit they derived from its use.

Subsequent trials have shown that sometimes the above mixture has no effect, at least on men.

PURGATIVES BY HYPODERMIC INJECTION.—It has been found (Paris *Médical*) that hypodermic injections of aloin (the alkaloid of socotrine aloes) will cause purgation when used in doses of one twenty-fifth of a grain. We can thus, by combining apomorphia and aloin, produce an action each way without having to introduce anything into the stomach.

SEVERE ACCIDENT TO A PHYSICIAN.—Dr. George Whipple Porter, of Providence, R. I., had his left foot crushed by a railroad accident on July 12th, necessitating amputation of the leg.

THE MASSACHUSETTS MEDICAL SOCIETY PRIZE was not awarded to anyone this year. The Committee state that no essay had been received during the past year, and that those sent in during the year before were unworthy of a prize.

RUSH MEDICAL COLLEGE.—Dr. J. S. Knox has been appointed adjunct-professor of diseases of children.

Dr. D. T. Nelson has been appointed adjunct-professor of gynecology in the same institution.

POISONING BY BOLOGNA SAUSAGE.—Thirteen Hungarians employed in the mines at Drifton, near Wilkesbarre, are said to have been poisoned by Bologna sausage. Five deaths are reported.

## SYPHILITIC IRITIS—EPIDEMIC CATARRHAL CONJUNCTIVITIS—CONVERGENT STRABISMUS;

BEING A CLINICAL LECTURE DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, APRIL 5, 1881.

BY DAVID WEBSTER, M.D.,

CLINICAL ASSISTANT TO THE CHAIR OF OPHTHALMOLOGY AND OTOLOGY.

GENTLEMEN:—This is the patient who came before you last week, and some of you may remember the diagnosis. It is a case of iritis, which, although severe a week ago, is now almost cured, and, as in the majority of instances, it is of specific origin. Upon examination, you will be able to see the deep injection around the cornea, now rapidly fading away, and the widely dilated pupil. You will also observe that the color of the iris is different from that of the unaffected eye—it has a greenish tint. The iritis had been in progress for a week or ten days before I saw the patient, and now about twenty-three days have elapsed since the beginning of the disease. Up to the time he came here, his eye trouble had been getting worse and worse, but since then it has steadily improved.

Having obtained a history of his case, which pointed to a specific origin, I directed that he should at once be thoroughly anointed upon both arms, from shoulder to elbow, with the common ungentum hydrargyri of the United States Pharmacopœia. In addition, you remember, I directed that he should protect his underclothing by cutting off the legs of a pair of old socks and drawing them over his arms and shoulders; otherwise, his clothing would have been daubed by this nasty application. It is always well to bear this practical point in mind in the treatment of these cases, for, by thus warning your patient, a very unpleasant condition of things will be avoided. About a half-drachm of the ointment should be "buttered" upon the arms, without trying to rub it in, every night and morning until the patient begins to feel its constitutional effects. He should not be allowed to wash or wipe off any of the ointment until the desired effect is produced. A very convenient way of determining this is to cause the patient to snap his teeth together rapidly, and if undue tenderness in the gums is experienced, it indicates that the constitutional effects of the drug have been obtained.* When this point is reached, it is time to stop the inunction and to instruct the patient to take an alkaline bath, and to have his clothing washed, so that no more ointment will be absorbed by the skin.

In addition the patient was directed to use a four-grain solution of atropine in his eye. Atropine, as I told you, is our sheet-anchor in the treatment of iritis. Unless it is used, adhesions are very apt to occur between the pupillary border of the iris and the anterior capsule of the lens; such adhesions are called *posterior synechiæ*. When formed, they interfere with the normal function of the pupil. If a healthy eye be exposed to a bright light, the pupil contracts; if darkness prevails, it dilates. When adhesions have taken place about the circumference of the pupil, no such contraction or dilatation can occur. If adhesions exist in the eye of a patient who has recovered from iritis, he will be much more liable to have recurring attacks of the disease than if there were no adhesions. The only way in which the recurrence of such attacks can be avoided is to perform an iridectomy—remove a part of the iris. By the vigorous use of a four-grain solution of atropia, we have prevented the formation of any permanent adhesions. Perhaps this would not have been accomplished had we used only atropine, or, in other words, except for the combined influence of atropia and mercury.

It is not wise to begin the internal administration of iodide of potassium immediately after the use of mercury is stopped, for, by so doing, a profuse salivation may be excited, and thus do the patient harm. It is well to allow a week to intervene. This practice is followed by some of our best practitioners. A good way to administer the iodide of potassium is in the form of a saturated solution, the dose being five drops in a little water three times a day after eating. The quantity should be increased to the extent of from one to three drops with each succeeding dose.* I have known patients to tolerate as many as eighty or ninety drops of the saturated solution of iodide of potassium three times a day, which is equivalent to three or four drachms of the drug, each drop representing a little less than a minim of the iodide. I saw a little child three or four years old, who, as I was told by Dr. Seguin, was taking a little more than a drachm of the iodide of potassium three times a day. The patient before you has only got up to seven or eight drops three times a day.

At first, when the patient was much worse than he now is, I directed the application of leeches to the temple. These, I think, had a good effect, and I want to call your attention to the good results which may be obtained from the application of leeches to the temple in cases of iritis. I would recommend their use whenever there is pain and whenever the case does not progress favorably. They should, in most cases, not be applied more than two or three times during the whole course of the disease, and usually not more than two at a time. I saw a lady to-day who had had seventy-five leeches applied to her temple within a month or two, for the relief of pain in her eye, and this, too, without any inflammation in the eye. You may be sure the lady was not benefited, but rather the reverse, by this excessive depletion.

In the case before you, improvement began as soon as the atropine had dilated the pupil; and as soon as the mercury had produced its constitutional effects upon the system the redness of the eyes became less, and now, as you can see, it has mostly disappeared—there is only a faint pinkish appearance of the eye. At present he does not see very well with the affected eye, owing to the paralysis of accommodation due to the use of atropine.

Sometimes we come in contact with the effects of the accidental use of atropine. Not long since a man who had received an injury to his eye applied for treatment at the Manhattan Eye and Ear Hospital. He was provided with a solution of atropine and a dropper, and instructed how often to use the drops in his eye. A day or two afterward an old lady

* Sometimes, however, your first intimation that the limit of toleration of the drug has been reached will be a strong mercurial fetor of the breath, a diarrhœa, or a persistent nausea.

* Until symptoms of the physiological effects of the drug show themselves. These are commonly either a coryza, an eruption, or a diarrhœa.

came to the hospital in a state of great mental excitement, stating that she could not see out of one of her eyes, and that she could assign no reason for the blindness. I had no idea that she was the wife of the injured man, but, during a course of cross-questioning, I happened to ask her the business of her husband, and she then stated that he had received an injury to his eye, for which he was being treated at the hospital. She also stated that she was in the habit of putting into his eye the drops which had been given him. This, of course, at once gave a clue to the case. Her mydriasis was, of course, due to having accidentally gotten some of the belladonna into her own eye. Such cases are not very infrequent. We see three or four cases of mydriasis every year due to the accidental instillation of a mydriatic; and when a patient comes to you with a dilated pupil, and there is nothing else the matter, you should always think of the accidental or intentional introduction of a mydriatic into the eye.

Speaking of mydriasis reminds me of an anomalous case which I have under treatment in private practice. The patient is a maiden lady forty years of age, who noticed that about a year ago her left pupil began to dilate without any known cause. It remained dilated for a month, and then the right pupil became dilated, and remained so for a while; afterward both resumed their normal size and then became dilated again. Since that time this alternate dilatation and contraction of the pupils in one or both eyes has continued. An eye-surgeon in Rochester saw the case early, and thought that the dilatation of the pupil was due to the accidental introduction of atropine into the eye. An interview with the lady convinced me that she was not a malingerer, and I sent her in consultation to a distinguished neurologist, who upon examination considered the curious phenomenon due to a displaced uterus, the patient complaining of uterine symptoms. She also complained of pain in the upper part of the back, neck, and in the lumbar region. A diagnosis of spinal irritation was made, and it was further given as the opinion of the consulting physician that the spinal trouble and the trouble with the eyes were due to uterine displacement or uterine disease.* I may say that this patient has considerable amblyopia, the vision being reduced to about one-fifth in each eye, without any visible lesion to account for it, the only departure from the normal being mydriasis and enlargement, with tortuosity, of the retinal veins.

### EPIDEMIC CATARRHAL CONJUNCTIVITIS.

This good lady tells us that she has had sore eyes for three or four days. Upon examination it will be seen that the conjunctivæ are a little reddened and swollen, and there is a little white matter to be seen in the corner of each eye. This lady is affected with a disease of the eye which is now epidemic in New York. Within the last fortnight I have treated in hospital and private practice not less than thirty or forty patients with the same disease—catarrhal conjunctivitis. I know no cause to assign for the disease, except it be due to the March and April winds and to the uncleanliness of the city, about which we have heard so much recently. The patient has suffered from pain, and, for the relief of this, she has applied poultices, which have, without doubt, aggravated her eye-difficulty. Notwithstanding, she states that the poultices afforded her relief. She has used bread-and-milk poultices and alum-curds, and has applied tea-leaves, which, being bound upon the eyes over night, constitute a poultice. Dr. Agnew formulates his belief in regard to poultices as follows: If you want to put an eye out, poultice it. When poultices are applied to the eye in cases like this, the ocular conjunctivæ will be found very much redder and more swollen than in those where no poultice has been applied. As a rule, in these cases the redness is usually confined to the under surface of the lid or to the palpebral conjunctivæ; but, in this lady, the latter will be found much paler and much less swollen than the ocular conjunctivæ. It is a typical case of catarrhal conjunctivitis aggravated by poultices. The white matter in the corners of the eyes and in the lower cul-de-sac is quite characteristic; it is not pus, but a slimy sort of mucus. If pus were flowing out in a considerable quantity, it would be indicative of purulent ophthalmia.

*Treatment.*—I will tell you what I have found to be the most effectual treatment in these cases. It is the following combination applied to the conjunctivæ in the form of a spray:

| | | |
|---|---|---|
| ℞. | Acid. tannic | gr. x. |
| | Sodæ biborat | gr. x. |
| | Glycerinæ | ʒ j. |
| | Aquæ camphora | ℥ j. |
| M. | | |

With a Davidson's atomizer, No. 55, this solution should be applied once daily to the everted lids. In using this solution in an atomizer, care will have to be taken to wash the instrument out with water each time after it has been used, in order to keep it in working condition. In addition to the use of the spray, the eyes may be bathed with a solution of salt in water, a teaspoonful to the pint. Some patients like to use water cold, some like it warm, and others prefer to have it hot—the temperature of the water is to be determined by the feelings of the patient; or the following wash may be used:

| | | |
|---|---|---|
| ℞. | Sodæ biborat | ʒ ij. |
| | Aquæ camphora | ℥ vj. |
| M. | | |

Of this a tablespoonful is to be mixed with a tablespoonful of hot water. This may be used for bathing the eyelids from three to five times daily. It requires to be freshly mixed every time it is used; and, unless you mention this fact, some patients who are not very intelligent will use the same water over and over again. As evidence that catarrhal conjunctivitis is not always dependent upon personal uncleanliness, I would state that I have seen within the last week four members of the present medical class, one oculist, and two general physicians with this trouble.

### CHALAZION.

This is the policeman from whose left lower eyelid we removed a chalazion last week. He is on hand again to-day to have another one removed. He says that there is one in the upper lid of the same eye which he wants out, for it "jumps terribly." For this operation a delicate knife (Graefe's) and spoon are required. The cyst is evacuated through the edge of the eyelid. A free incision is to be made into the tumor, and, with the lid between

* July 15, 1881. This patient was afterward examined by Prof. T. G. Thomas, M.D., who wrote as follows: "Miss X—— has a fibrous tumor of the uterus as large, or nearly as large, as your head. It extends up nearly to the umbilicus and is very tender to pressure. At the meno-pause it will diminish in size, but until then nothing can be done for it except general tonic means. This tumor is probably the cause of the eye-trouble."

your thumb and finger, the contents of the sac are to be scraped out with the spoon.

CONVERGENT STRABISMUS.

You will, perhaps, be able to make a diagnosis from a distance in regard to this young man's eyes. It is a case of convergent strabismus. You will observe that he fixes with the left eye and turns the right eye in. When I cause him to fix with the right eye he turns the left eye in. This is what is called *concomitant squint*. Now, this young man wants to have his eye straightened, and the question arises whether an operation for this purpose is justifiable. Let me, at the outset, warn you against operating for convergent squint before you have thoroughly examined the patient's vision; otherwise you may be the victim of a very unpleasant accusation. A patient upon whom you have operated may come to you after the operation and accuse you, and honestly too, of having ruined his eyesight, and, without having tested his power of vision in both eyes previous to the operation, you are in a somewhat defenceless position.

There are many intelligent individuals who have lived to adult life, who have been able to see well with only one eye, and yet are not conscious of any defect in their vision. I have seen several such cases, and have already published the history of a very remarkable example of this condition of affairs. The patient was a lawyer over thirty years of age, who consulted me about an operation upon one of his eyes. In the course of an examination, I found that he was so blind in the other eye that he was unable to count fingers in the central part of his field of vision, though he could do so with difficulty in the peripheral part of the field. Up to this time he had never noticed the fact that he could not see with one eye as well as with the other. He had most probably been born with this defect in his vision, as ophthalmoscopic examination showed an extensive plaque of atrophy of the choroid, including the macular region.

While in cases of convergent strabismus, not alternating or periodic, the eyesight is invariably impaired to a greater or less extent, I do not now remember ever having seen a case in which perception of light was lost. It not infrequently occurs, however, that such patients are so blind in the squinting eye as to be only able to count fingers. Defective vision, due to disuse, as is the case in strabismus, is spoken of in the books under the name of *amblyopia ex anopsia*.

We have already tested the vision of this young man and find it $\frac{20}{30}$ in his left eye, which is two-thirds of the natural vision. The ophthalmoscope reveals the fact that he has $\frac{1}{4}$ hypermetropia. In all cases of convergent strabismus we expect to find some degree of hypermetropia as the cause. When we examine a case of convergent squint, and find emmetropia, we consider it so rare that we forthwith rush into print with an account of the case. This patient is unable to count fingers with his squinting eye, but he can perceive light with it. There is, in his case, a cause for the amblyopia, and one which is rarely found in convergent squint. There is atrophy of the right optic nerve and of the choroid. He must have had some previous eye-trouble—perhaps a neuroretinitis in infancy. He tells me that his present trouble came on in childhood. I think he must have had some difficulty of this kind, and that it was followed by atrophy and squint. I have stated to him that I do not think the operation will improve his sight very much—perhaps not at all. In cases of strabismus, where there is no reason to the contrary, it is not uncommon to see an eye with vision $\frac{20}{100}$ improve after the operation to $\frac{20}{70}$ or $\frac{20}{50}$ within a week, but in this case we cannot promise any such improvement, because the optic nerve and choroid have undergone atrophy. Notwithstanding this, he says that he wants the operation performed in order to improve his appearance, and I sympathize with him. On this ground alone I think the operation fully justifiable, and would recommend to the patient to come next week to have it performed, as I learn that he has just eaten a hearty dinner of chicken and vegetables, and it would be very unpleasant to administer ether under these circumstances, for he would probably vomit his dinner. I make a practice of never operating upon a patient who has recently eaten a hearty meal, unless it is absolutely necessary. Then, too, there is another reason for not administering ether with a full stomach. You probably remember the case which occurred in Bellevue Hospital a few years ago. A patient, who was to be operated upon, was, a short time before the operation, surreptitiously given something to eat by some friends. During the administration of the ether the patient died, and it was found upon the post-mortem that he had choked to death, a large piece of meat being found in his throat.

## A CASE OF POPLITEAL ANEURISM,

IN WHICH THE LIGATURE WAS SUCCESSFUL AFTER THE FAILURE OF DIGITAL COMPRESSION; WITH TRACINGS, WHICH SHOW THE VALUE OF THE SPHYGMOGRAPH IN THE DIAGNOSIS OF ANEURISM.

BY N. P. DANDRIDGE, M.D.,

PROFESSOR OF GENITO-URINARY DISEASES IN THE MIAMI MEDICAL COLLEGE, SURGEON TO THE CINCINNATI HOSPITAL.

(Read before the Cincinnati Medical Society.)

FEBRUARY 2D, G. S——, was brought to the private ward of the Cincinnati Hospital, and placed under my care, by Dr. McCullough, of Catlin, Ill., from whom I learned the following history: Some eighteen months ago he received a wound from the accidental discharge of a pistol. The ball entered the outer side of the left leg about its middle, and coursed downward, but did not come out. After the accident he rode fifty miles on horseback, and when he dismounted, the leg was greatly swollen and he found he could not straighten it; it was flexed at nearly a right angle. The ball was not extracted. He was confined to bed for the next nine weeks, at the end of which time he was able to be up and about, though the leg remained much larger than the other, especially in the upper part of the calf. Motion in the knee-joint was completely restored. The return of motion was gradual, and not due to any forcible manipulation. Some two years ago he contracted syphilis, which has manifested itself in several slight outbreaks since. His health otherwise has been remarkably good.

He presented the appearance of a well-nourished, robust, healthy man. Over the legs some pigmented spots were found; these, with induration of the inguinal glands, were the only evidence of syphilis

manifest. His age was twenty-eight. His occupation had been that of a farmer. The left leg was larger than the right, measuring in the upper third fourteen and one-half inches, to eleven and one-half of its fellow of the opposite side. Encroaching upon the popliteal space from below was a pulsating tumor; this tumor above was distinctly circumscribed, and presented to the touch the impression of a thin and yielding sac; below its boundaries were lost in the general swelling of the calf. The bruit was distinct, though not loud, and the pulsation was markedly expansile. The movements of the joint were not interfered with, and, although some pain was present, it was not excessive, and did not interfere with his walking about. Pulsation was noticed in the tumor some two months ago, and since then the size of the mass has greatly increased. Dr. McCullough being obliged to return home as soon as possible, it was decided to try the effect of compression of the femoral at once. Digital compression of the common femoral against the pelvic bones was commenced the next morning, and continued for nine hours, with the effect of reducing the force of the circulation and producing marked consolidation in the sac. The circumference of the limb was reduced one inch.

The compression was made by a relay of assistants; the artery was controlled by the thumb, which was fortified by a conical shot-bag tipped with felt resting on it. The shot-bag was suspended by rubber tubing to secure continuous action, and, in order that the pressure should always be perpendicular, an upright iron bar passed to the bottom of it, and played freely through a ring between the tubes. The whole apparatus was suspended by a spring scale, so that the exact amount of the pressure could be seen at a glance. By this means the advantage of tactile sensation was secured, while nearly all muscular effort was spared, and frequent changes of assistants avoided. One assistant maintained continuous compression for an hour an a half. The compression was well borne; the only pain complained of being under the thumb, where the integument became reddened and irritated. This was due to neglect to shave the part; the inguinal glands also showed some effect of irritation. The result of this effort was reduction of the size of the limb one inch, marked consolidation of the sac, and diminution in the force of the pulsation. It clearly proved that the aneurism was still circumscribed and not diffuse, as had been supposed, for its boundaries could now be easily made out. We were thus encouraged to attempt a second trial, more prolonged than the first and under more favorable circumstances, after some days of rest in bed. He was therefore put on large doses of the iodide of potassium, and kept in the horizontal position for ten days. During this time the advantages gained by the first trial of compression were gradually lost, the pulsation again becoming stronger and the tumor softer and more yielding. While he was thus in bed, Dr. Keyt was kind enough to make a very complete set of sphygmographic tracings of the case. These tracings are given herewith, and I will defer consideration of them until the history is completed. February 13th, compression was again attempted and prolonged twenty-four hours. During the latter half of this time morphine was given hypodermically. This trial produced some exhaustion, which soon passed off. The effect was much the same as the first attempt—solidification of the tumor and diminution in the force of the pulsation. Flexion of the limb was now tried, but without effect, and finally the artery was controlled by a horse shoe tourniquet over Hunter's canal; this was so painful that it could only be continued for two hours. The advantage obtained by these trials was soon lost, and the tumor began to encroach more and more on the popliteal space, and to increase in size. February 23d, the femoral was tied at the point of Scarpa's triangle; the operation was conducted antiseptically, and catgut was used for the ligature. Pulsation at once ceased, and never recurred in the tumor; in the posterior tibial it was again perceptible at the end of a week. The wound healed slowly, with some suppuration, and locally did not present the course of an antiseptic case, though there was neither pain, nor fever, nor any constitutional disturbance. The aneurismal tumor became harder and firmer, and the man left the hospital April 5th, able to walk perfectly well on the leg. Although compression proved a failure in this case, I am satisfied the time occupied was not thrown away, but that it assisted materially in putting the man in the best condition for the success of the ligature. The statistics of Holmes seem to show that operations undertaken after compression has been tried are not quite so favorable as those which are performed immediately. The failure of compression in this case conforms to the opinion expressed by the above-mentioned author, that rapidly growing aneurisms, with thin and yielding sacs, are not favorable ones in which to effect a cure by compression.

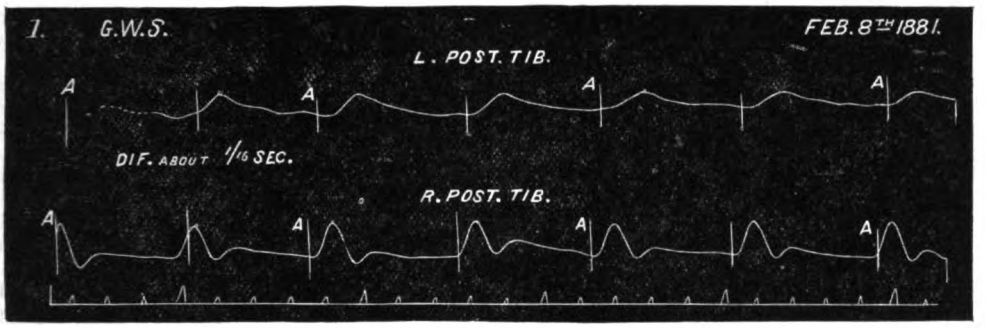
The contrast between the pain suffered from the two modes of compression was most striking—instrumental compression could only be endured for two hours, while the digital was maintained for twenty-four hours without any very great suffering. The relation of the aneurism to attacks of syphilis is of interest and importance. There is a general feeling that syphilis is an important factor in the production of aneurism. Many surgical writers speak of this relation as well established. The syphilographers are, however, much more guarded in their expression of opinion, and at the present time it cannot be said that the evidence on this point has reached more than a plausible hypothesis. The question is one of importance, involving, as it does, the propriety of using antisyphilitic remedies, and especially mercury. In the case just reported, mercury, and not iodide of potassium, was indicated from the first stage of the disease, but was not used for fear it might hinder the formation of the clot. In this I am by no means sure I was not in error. I have not been able to find any authority upon the subject. It is difficult to understand any relation between the wound in the leg and the formation of the aneurism. Its position was such that it could not possibly have affected the artery, while the leg was gradually straightened so there was no overstraining or stretching by any forced manipulation.

The tracings given are very complete, and show, in a typical manner, the characteristic deformation of the pulse from aneurism, and indicate how reliable a means it may be for diagnosis in doubtful cases. I am indebted to Dr. Keyt for the tracings themselves, and for an explanation of their significance. They were taken by his compound sphygmograph, by which tracings of arteries on opposite sides of the body are recorded at the same time, thus offering for comparison, side by side upon the same slide, the normal and the affected pulse.

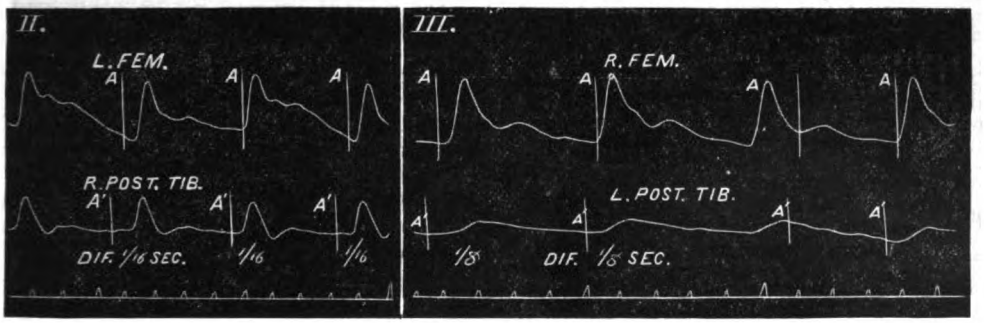
No. I. Traces of the two posterior tibial arteries, taken simultaneously behind the malleoli. The left is typically deformed, showing the sloping ascent, rounded top, and imperfect marking of the secondary

waves, and marked delay of the left on the right, which is the normal pulse. This delay is $\frac{1}{16}$ sec.

Nos. II. and III. are confirmatory of the correctness of this measurement. No. II. shows simultaneous tracings of the left femoral and the right posterior tibial, and thus gives the delay which normally ex-

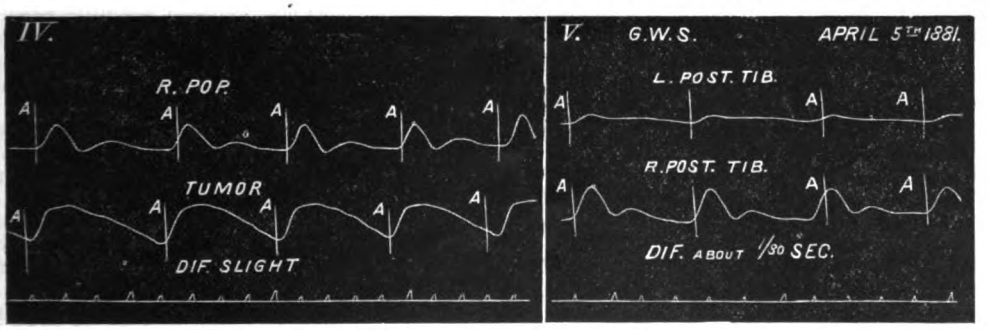


ists between these arteries; here it is $\frac{1}{16}$ sec. No. III. shows the tracing from right femoral and left posterior tibial, and gives a delay, $\frac{1}{8}$ sec. Subtracting $\frac{1}{16}$ from $\frac{1}{8}$, it leaves $\frac{1}{16}$ as the amount of extra delay caused by the aneurism. This is the amount found by comparing the two posterior tibials.



No. IV. Tracings of right popliteal and tumor, showing rounded top, absence of secondary wave, and slight delay in the tumor.

No. V. Posterior tibial arteries after the return of the circulation in the left through the collateral circulation, amplitude greatly diminished, and delay $\frac{1}{30}$ sec.



The delay of the collateral circulation is not nearly so great as that of the aneurismal tumor.

These tracings show that deformity and delay are both found in the pulse beyond an aneurism; the latter is especially characteristic of this condition, and when it is present may be considered as a conclusive sign of aneurism, with certain rare exceptions. This delay is only apparent where simultaneous tracings can be taken, and is determined by "comparing the apex of the waves of the two pulses."

Dr. Keyt, in a paper which appeared in the MEDICAL RECORD, November 29, 1879, in estimating the diagnostic value of sphygmographic tracings in aneurism, says:

"1st. Deformation of the pulse beyond a suspected aneurism is of little value as indicating the presence of aneurism, but indicates rather the presence of arterial obstruction which may originate from other conditions, as well as from aneurism. Absence of such deformation is no evidence of absence of aneurism.

"2d. Delay of the pulse beyond a suspected aneurism is strong evidence of the presence of aneurism, and, when arterial obstruction and vaso-motor paralysis can be eliminated, is conclusive of aneurism; absence of delay is of no value as indicating the absence of aneurism.

"3d. In aneurism already diagnosed, deformation of the distal pulse indicates the presence of concomitant arterial obstruction.

"4th. In aneurism already diagnosed, delay of the

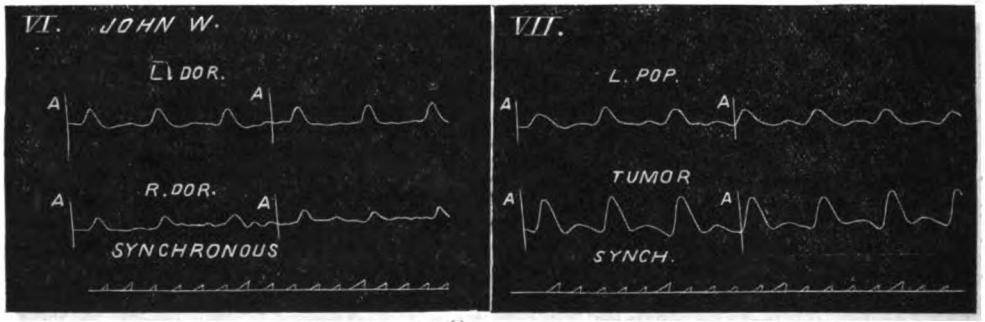
free distal pulse indicates one with free communication, large cavity, and yielding walls; while absence of pulse-delay indicates one with narrow orifice or small cavity."

The delay of the wave in aneurism has been studied and experimentally explained by Franck, in the *Journal d'Anatomie et Physiologie.* By means of an ingenious contrivance he has shown that a wave passing through an elastic tube is markedly delayed, provided there is a sudden expansion of the tube at any part; these are the conditions of an artery affected by aneurismal dilatation.

Passing down the artery, the pulse-wave must fill and expand the dilatable aneurismal sac before it proceeds.

One more important diagnostic factor is given by the pulse-delay. Dr. Keyt's fourth conclusion shows that marked delay indicates an aneurism "with free communication, large cavity, and yielding walls." Now, these are the aneurisms which are the least likely to be treated successfully by compression, as shown by the tables of Holmes; while absence of delay, where the diagnosis has already been made, indicates an aneurism with "narrow orifice or small cavity," or unyielding walls. Here the conditions are all favorable for successful compression.

The sphygmograph may therefore offer an important means of estimating the probable result of compression in a given case.



The exact position of the aneurism and the artery affected can often be determined with greater accuracy by this than by any other means. Thus, in determining whether a given aneurism is situated upon the ascending aorta, or on the innominate, or on the transverse aorta: if the innominate is affected, the right radial will show the characteristic deformity and delay, while the left will be normal. If the ascending aorta is the seat of disease, both radials will be alike affected; while, if the aneurism is beyond the mouth of the innominate, the left only will be deformed. These points are all brought out in Franck's essays.

The above conclusions received additional confirmation from the following case, where neglect to appreciate the significance of the sphygmographic tracings led to the grave error of operating under a mistaken diagnosis, where no aneurism was found.

J. W——, aged twenty-four, entered the Cincinnati Hospital, August 3, 1879, for a gunshot wound in the right popliteal space, which had been inflicted the day before by a policeman. The wound was about one-third of an inch in diameter, there was very little hemorrhage, no swelling, and the joint was painful on motion. The leg was placed flexed upon a pillow, and cold applied. The case progressed favorably, without any marked symptoms for some days, so that it did not require any special attention beyond being kept quiet in bed. August 15th, twelve days after admission, my attention was called by the interne to a pulsating tumor in the popliteal space, which he had discovered the day previous. On examination a swelling was found presenting a marked bruit, characteristic thrill to the touch, and expansile pulsation. The circumference of the knee semiflexed was one and one-eighth inch greater than that of the opposite side, measuring fifteen and three-eighths on the right, and fourteen and one-half on the left. This swelling extended down the calf, which measured, right, thirteen and six-eighths; left, twelve and one-half. To the hand on the tumor it imparted the sensation as if fine shot were rolling under the fingers. Pressure on the femoral artery stopped the pulsations completely; forced flexion only partially. The symptoms and the history seemed clearly to point to a traumatic aneurism as the cause of the trouble—a swelling with marked bruit and thrill, and expansile pulsation, developing gradually in two weeks after a gunshot wound directly over the popliteal artery. The case was seen by the surgeons of the hospital, and by a number of other medical men, and no one expressed the slightest doubt of its character.

It was decided, therefore, on consultation, to treat it as a wound of the artery, and to place a ligature above and below the seat of the supposed injury. August 19th, the Esmarch bandage was applied, and an incision was made in the popliteal space, taking the gunshot wound as the centre. The track of the bullet was soon lost; the artery was exposed, but presented no evidence of aneurism or wound. The incision was prolonged above and below, and the vascular cord was exposed for fully two inches, but nothing was found to explain the symptoms. Owing to the use of the Esmarch bandage, we were deprived of the benefit of the pulsation of the artery, which would have served as a guide; but, fearing hemorrhage, we were afraid to loose it during the search for the aneurism. During the dissection the artery was wounded, which necessitated a double ligature above and below. This ligature, which was of catgut, completely controlled the pulsation when the Esmarch was removed, and so we were still left completely in the dark for an explanation of the case. The operation was made under the spray, and an antiseptic dressing applied; this was, however, very imperfectly done. The case progressed favorably until the 21st, when the temperature rose to 102°. The dressing was removed, and the edges of the wound were found swollen and tense, and some bloody serum escaped from the drainage-tubes; there was no odor, and the general condition was good.

On the 25th, the seventh day after the operation, a violent hemorrhage came on, which necessitated removal of the dressings. This was finally controlled after a severe loss of blood. No healing had taken place, and the wound was found filled with blood and shreds of sloughing tissue.

The cause of the hemorrhage was the melting down of the catgut ligatures before the artery had been occluded. Silk ligatures were now used, and the vessel cut through between them. As we were about to close the external wound, some pus welled up from the lower end. This was found to come from an abscess which extended down the calf. This was laid open by extending the original incision until it was eight inches long. This abscess I believe arose subsequently to the operation, though it is possible that it may have existed previously, and given rise to the symptoms of aneurism by transmitting the pulsation and bruit from an underlying artery.

Whether this is the correct explanation or not, it is certain that during the operation we found neither wound of artery, aneurism, or abscess, nor, indeed, any condition which could explain the symptoms, which had existed. The result of the case for some time remained doubtful. A large slough formed over the instep, which destroyed the tendon of the tibialis anticus, and an abscess formed in the calf.

The man left the hospital at the end of about six months, with a leg saved, it is true, but permanently impaired. Before the operation, Dr. Keyt took tracings of the dorsalis pedis artery of each foot. It will be seen that they do not present any of the characteristics of the aneurismal pulse; there is neither deformity nor delay.

No. VI. Tracing of right and left dorsal arteries in a case of supposed traumatic aneurism of the popliteal artery, but which was probably an abscess. These pulses are synchronous, and show none of the characteristics of aneurism.

No. VII. contrasts the pulsation in the tumor and in the popliteal of the sound side; comparing this tracing with No. IV., the difference is most marked. There the tumor tracing shows a slanting ascent, rounded top, and absence of secondary wave; while in No. VII. the ascent is abrupt, the top of the wave sharp, and the secondary wave well marked, and there is decided increase in the amplitude as compared with the opposite side.

Had I appreciated the significance of these tracings, it is possible I might have avoided the error I committed in operating. In another case, even when the ordinary symptoms of aneurism are all present, I shall hesitate to operate if the characteristics of the aneurismal pulse are absent, as shown by the sphygmographic tracing.

These two cases supplement one another: the first gives an example of a perfectly typical tracing in an undoubted aneurism, while the second shows that the absence of the characteristic tracing may well throw doubt upon the diagnosis in a given case, even when all of the other symptoms seem conclusive.

---

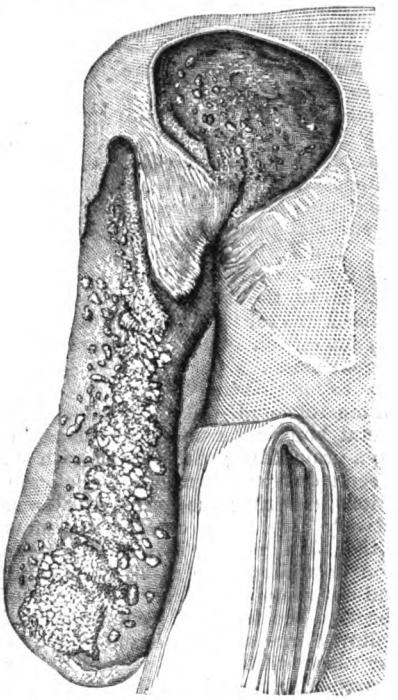
GELSEMIUM SEMPERVIRENS IN NEURALGIA OF THE ALVEOLAR BRANCHES OF THE TRIFACIAL.—Dr. Roviralto endorses the use of gelsemium sempervirens in neuralgiæ of the alveolar branches of the fifth pair. Giving it in doses of ten to twelve drops (!) of the tincture to a cup of sweetened water, he has obtained gratifying results in obstinate cases.—*Rev. de Med. y Cir. Pract.*

## SKIN-GRAFTING WITH GRAFTS TAKEN FROM THE DEAD SUBJECT.

By JOHN H. GIRDNER, M.D.,

NEW YORK.

CHARLES JOICE, aged ten years, who lives in Morrisania, is the original of the photograph from which the accompanying cut was made. In the latter part of June, 1880, while sitting on a door on which there



was a steel hinge, he was struck by lightning, and became comatose, in which condition he remained for several hours. He was brought to Bellevue Hospital and placed in Ward 12, at that time under my charge. When his clothes were removed the skin came off his left arm and scapula, leaving the large raw surface seen in the picture. This surface was treated by different means for some weeks, until a healthy granulating surface was obtained all over the affected part.

About this time, a healthy young German, who had attempted suicide by cutting his throat, was brought to the hospital, and died within a few hours. Six hours after his death, I went to the dead-house and removed a portion of skin from the inner side of the thigh, where there was least hair, and the skin most delicate. Having cut this piece of skin into a great many small pieces, I applied them and dressed the surface after my own method, which is to apply first, next to the grafted surface, a piece of the green protective used in Lister's dressing; over this I strap the ulcer with ordinary rubber or adhesive plaster, and over the whole throw a roller loosely. The object of the green protective is to prevent the grafts from adhering to the plaster and being torn off when the dressing is removed. The strapping is simply to make pressure, which must be firm and evenly applied.

After the dressings had remained on for four days, they were removed, and after some little discharge

had been washed off, I had the patient photographed. About one-fourth of the grafts had failed to take, and were washed off when the wound was cleansed. The remainder have attached themseves to the ulcer, and, as will be seen from the cut, the lower and central portions of the ulcer on the arm are already covered with a thin, delicate skin, as a result of the fusing together of the little islands of skin, each graft serving as a point of departure for the formation of these islands. As in other and similar cases, cicatrization would have doubtless gone on to complete cure in a short time, but for an attack of erysipelatous inflammation, resulting from the low condition of the boy's general health, and his exposure to other cases of that disease, which destroyed a large portion of the newly formed skin, requiring subsequent graftings, but finally resulted in a cure, with much less of contracting cicatricial tissue than is commonly witnessed after recovery from such extensive burns.

Skin and mucous membrane removed from the living in surgical operations have been often used for grafts. But I wish to state here my claim, that the idea of removing skin from the cadaver and grafting it on to the living subject is original with me, and that I was the first to perform this operation, which has since been done many times successfully by other gentlemen.

It seems to me that any one who has witnessed, as I have done repeatedly, skin taken from the dead body several hours after death return again to life, adhere to a granulating surface, and with surprising rapidity send out prolongations of delicate skin in all directions, covering the surface with a new skin comparatively free from contraction, must agree with me that skin-grafting is in its infancy, and that when men of ability have given it more attention, and found out the possibilities of the proceeding, we may expect to see frightfully contracting cicatrices which follow burns and nævi removed by excision, and their places filled with a skin almost as perfect as the surrounding, and which has been removed from the dead or living body of another person.

## THE VOICE AS A THERAPEUTICAL AGENT.

By R. VAN SANTVOORD, M.D.,

NEW YORK.

During one of the sessions of the American Laryngological Association, held in this city a year ago, Dr. Knight, of Boston, asked the association by what principle its members were guided, when treating laryngitis in singers, in allowing them to resume the use of their voices. Although many prominent laryngologists were present, he received no answer. It seemed somewhat remarkable that so eminently practical a question should not have received a definite solution from the members of the profession there present. It is the object of the present paper to give an answer to this question, founded on certain well-established principles in therapeutics and on the practice of singers when suffering from slight catarrhal inflammation of the larynx.

In the treatment of an acute inflammation of a mucous membrane, the conjunctiva for example, it is well known that irritants are harmful during the active stage of the process; during the latter stages of the disease, however, they are useful. These therapeutical results demonstate that we are dealing with two very different states of affairs. The so-called "latter stages of the disease," in fact, are not, properly speaking, stages of the disease at all. The active process has ceased, leaving the membrane with relaxed blood-vessels, encumbered perhaps with the products of inflammation and badly nourished. The effect of the application of an irritant is to rouse the sluggish circulation, and thus to promote the absorption of morbid products and restore the nutrition of the part. We find an exact parallel to this process in the use of motion in the treatment of articular rheumatism. So long as the joint is spontaneously painful and tender, motion aggravates the disease. When, however, the acute stage is passed—when, in fact, the disease is gone and we have to deal only with its effects, motion of the affected joints, carried on within due limits, restores the nutrition and functions of the parts. But, in either case, if the remedy—the astringent or the motion—is used in excess, it will rekindle the original evil.

Now, the use of the voice is to inflammation of the tissues of the larynx exactly what motion is to inflammation of the joints. During the active progress of disease, its use is decidedly and unequivocally harmful. The acute stage of a catarrhal inflammation is, however, short. When the acute stage is past, the moderate use of the voice may be made as a very valuable therapeutical agent. Well-trained singers know that when their voices are a little husky as the result of a cold, that the voice may be "cleared" by practising a few simple exercises in notes well within their compass, and sung with very moderate loudness.

The advice to a singer to use his voice must, however, be given with great caution. The efficiency of the remedy depends on the discretion of the individual singer, and, above all, on his *method of singing*. Many singers, as is well known, have grave faults in their mode of using their voices. Indeed, comparatively few are even approximately faultless. A faulty method of using a voice is directly provocative of inflammation. If a singer whose method is very defective is under treatment, the advice to "use his voice" will result, probably, in an aggravation of his malady. The writer has, in his own person, frequently experienced the beneficial effect of a moderate use of the voice, in the way above indicated, when suffering from the effects of slight laryngeal catarrh. He is convinced, furthermore, that he has eradicated, to a great extent, a tendency to such attacks by using his voice systematically in singing during a period of some months.

The evils resulting from a faulty method of using the voice, and the necessity of recognizing it as a source of disease, could not be better illustrated than by the following case, which has come to the writer's knowledge: A young and robust clergyman became almost unable to use his voice in public speaking, and was under the treatment of a throat specialist in this city for a long time, without being benefited. He was even brought before the Laryngological Society, but no one who saw him could account for the obstinacy of his trouble. He finally went to a singing-teacher, who taught him in a short time to use his voice properly. The result was that his symptoms disappeared, and he can now speak for an indefinite time without weariness. The writer's information regarding this case comes from lay sources, so that he cannot state what lesions were observed. The fact that the patient was a fine instrumental musician probably aided him in recognizing his defects when pointed out, and in remedying

them. The obvious corollary of this case is that the physiology of the voice has not received the attention which it should receive.

In order to give intelligent advice in regard to the use of the voice, the physician should himself be a vocalist, or at least should have a sufficiently well cultivated ear to be able to detect grave errors in his patient's mode of singing. The writer cannot pretend to have a sufficiently thorough knowledge of the subject to speak with entire confidence as to exactly what are the faults, in the use of the larynx and its appendages, which give rise to irritation of the parts. The physiology of the voice is a field in which, from his own study of the matter in the cultivation of his own voice, he believes there is still much to be done. Physiologists who are not thoroughly trained vocalists are not competent to study the subject, because they are apt to mistake faults in the employment of the vocal organs for essential features in the physiology of the production of the voice. The writer is convinced that errors have crept into some standard works on the subject, because observers have not always had the knowledge requisite to enable them to select fit subjects for study.

It can at all events be stated, without fear of contradiction, that the commonest and probably the gravest of faults in the use of the vocal organs consists in the violent dragging up of the larynx during the production of a note. This dragging up is associated with a general rigid contraction of all the muscles of the pharynx. It is this which gives the so-called "throaty" quality which is so common among untrained and badly trained singers. This method of singing soon causes the voice to become weary and husky, probably from interference with the circulation of the blood in the parts.

It can probably be laid down as a rule that if, on asking a patient, who is suffering from laryngeal inflammation, to sound a note, the larynx is observed at once to rise, the use of the voice by that patient will only aggravate the disease. This observation of the position of the larynx during vocalization may prove to be a sufficient guide, to those physicians who have not been sufficiently educated in vocal music to know, from the quality of the notes sung, whether the singer's method is faulty enough to prohibit the use of his voice as a therapeutical agent or not.

The writer does not wish to be understood as advocating the use of the voice in cases of grave structural changes in the larynx. The above remarks apply *only* to patients suffering from the latter stages of acute or from chronic catarrh of the larynx.

In treating a patient who is a vocalist, suffering from catarrhal inflammation of the larynx in its later stages, the physician should ask him to sing a few notes. If the physician is fortunate enough to have a cultivated ear, he can tell in an instant whether the patient sings with a forced, "throaty," smothered voice, or in a full, easy, natural tone. If the physician cannot make this distinction, he may possibly get a tolerably reliable indication in the movement of the larynx, as above suggested. If the voice is properly used, its employment, as above indicated, will prove directly curative. When a patient, whose vocalization is very defective, asks when he ought to begin to use his voice again, the answer, if given with perfect honesty, should be: "Never, unless you put yourself under a competent instructor, and learn to use it properly."

In concluding this paper, the writer desires to state that he does not claim to have advanced anything new or original. The facts on which it is based are generally known, and will probably be new to very few who peruse this statement of them. There seems, however, to be a tendency to study disease from a purely pathological standpoint, and in practice to lose sight of commonly known facts which are of the greatest service in the cure of patients. It is just this kind of information which is apt *not* to get into text-books. It does not seem superfluous, therefore, to bring it forward occasionally, although the so doing does not add anything to the aggregate of knowledge.

26 East 125th Street, July 12, 1881.

# Reports of Hospitals.

## HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

### Service of Dr. WILLIAM PEPPER.

### CLINICAL REMARKS ON EPILEPSY.

To-day I desire to offer a few remarks on the treatment of epilepsy. At first I will ask your attention to a few different types.

Here, for instance, is the case of a young man, aged eighteen; his head has been noticed to be large since his fourth month. He has never been well—always more or less delicate or sickly. It is a case of chronic hydrocephalus, not rickets, but the enlargement is due to a serous effusion into the ventricles of the brain, or it may be on the surface of the brain. The square protrusion of rickets is lacking, but we have the high, spherical development and depression of the orbital plates. We also notice the contrast between the large brain-case and the comparatively small features. We find no traces of rickets at the end of the long bones, nor at the ribs.

It is a state of chronic hydrocephalus which has been arrested and resulted in a prolongation of life. He is now eighteen years old. Sometimes such patients live to adult life, and even to middle age, the individual being possessed of moderate mental powers. The father and mother are both healthy, but the mother had chorea at the time of his birth. Of their eight children all are healthy but William, our patient.

He has been having fits since his eighth year. His first attack lasted several hours. During the last month his fits have become more frequent; whereas, formerly, he had about three fits a month, he now has had nine within twenty days. The attacks come on suddenly, without warning. He immediately loses consciousness. Sometimes the disordered muscular movements are so brief that they scarcely attract attention, and at other times they are very violent and prolonged, and he is tossed about and almost torn to pieces by the violence of the attack.

The fits are connected with organic disease of the brain, and consequently we speak of them as symptomatic. There is a positive lesion in this case, viz.: the distention of the ventricles, which gives rise to constant irritation by pressure on the motor ganglia at the base of the brain. It is probable that in the first convulsion a rupture took place of some of the motor fibres of the left side, which caused a right-sided hemiplegia from which even yet he has not recovered. It is quite possible that

owing to the pressure, the meninges have become somewhat roughened, and this may play some part in the production of the fits. Here we have an organic disease of the brain exciting the fits as a symptom. Diseased conditions need not be at the base of the brain, nor yet in the spinal cord, for us to have symptomatic epilepsy.

The next case is a gentleman twenty years of age, who presents a most interesting condition, and demands our utmost consideration. He is healthy, strong, has had no constitutional disease, but had remarkably bad luck in regard to falls and blows on the head. Ten years ago he got a blow with a club on the right side of the head, which knocked him unconscious. Later than this, about eight years ago, he was thrown out of a wagon and struck on his head. Four years ago he had a somewhat bad attack of typhoid fever. About eight years ago he fell on the ice and was insensible for two hours. All of the family are healthy.

The first fit occurred seven years ago, when he was thirteen years old, some months after he had fallen on the ice. From that time he had no fit until June, 1880, when he was unconscious for one hour and a half. The third fit occurred on the third of the following October; the fourth on the first of March, 1881; while the fifth and sixth have occurred respectively on the second and the twelfth of April. Lately he has noticed that after exertion he has slight attacks. On a few occasions only he has had a distinct aura, which began at the base of the chest.

Examining his skull we find no depression of bone nor signs of a fracture, nor can even a scar be found. It is therefore very difficult to determine the precise nature of the cause. We have distinct epileptic attacks combined with the petit mal.

It is often very difficult to determine in such cases whether the attack be an essential epilepsy or symptomatic of some local lesion about the head. We are all liable to epileptic attacks. Reflex excitability resides in all. The more healthy the nerve-tone, the less liable are we to have morbid muscular movements. As the nerve-tone is impaired a morbid excitability of the nerve-centres presents itself, and then also do we meet with the irregular muscular movements.

Irritation from undigested food in the intestinal tract, the presence of worms in the intestines, a tooth pressing on a tender gum, or a splinter in the matrix of a nail, all may cause violent convulsive movements—a reflex fit. If, in addition to this source of irritation, we have weak nerve-centres, then the fits are more likely to occur, and yet more likely if the irritation is nearer to the nerve-centre. When the centres become abnormally excitable, we have a state predisposing to convulsions. This predisposition may be so marked that the slightest irritation may cause the fit. This last condition described is sometimes a congenital affair, affecting certain parts of the nervous system more than others. It is a morbid state of the nervous centre, which may be acquired after typhoid fever, may come from malnutrition, from anæmia, from overwork, from depressing passions; all may breed the morbid condition that is at the root of epileptic convulsions.

A blow on the head may produce these convulsions, a spicule of bone may cause the irritation, while concussion may so impair the molecular structure of the brain that the organ becomes permanently injured. With such conditions there is developed an increased susceptibility to nervous irritation. Here in this case it is exceedingly important to determine which of these two causes exist, as on them depends our treatment.

In examining epileptic patients it is very necessary to find out distinctly and definitely when the first attack occurred. In proportion as the attacks occur earlier in life, the more probable is it that they have a congenital origin.

This lad is fifteen years of age; as a boy he was unusually bright, active, and energetic; he went into everything with his whole soul. In the summer (May) of 1879, while he was playing in the midday sun, he had his first fit. Since then he has had a number of these attacks. He has been under the regular epileptic treatment, and has improved only temporarily.

Latterly the epileptic attacks have been mixed up with morbid excitability of the nervous system, as manifested by restlessness, talking at night, and other phenomena of irritation. With this there was evidently serious impairment of nutrition. This patient probably overtaxed his nervous system, and his nutrition was impaired to a great extent, when some sudden excitement brought on the attack.

Unfortunately, there is a possibility of his having had an attack of true sunstroke, and I have often seen convulsions following sunstroke when a meningitis has been caused, the subacute meningitis occasioning fits in after-life. Probably, however, as the boy worked hard and grew thin, the convulsions are functional—are due to a state of malnutrition.

We have now seen instances from the worst to the best, cases of convulsions occurring under widely different conditions—all included under the name of epilepsy.

Let us look for a few minutes at the treatment from a general point of view.

In the first place, when you see a case, look for the cause, and see whether it is remediable. Sometimes we find a depression of the skull; such cases should be trephined at once, and the condition of the bone examined. Whenever you can locate the seat of injury, use the trephine; the operation is rarely followed by any trouble. The study of localization by means of the fact that injuries at certain points give rise to more convulsive movements than is observed in others, may prove a valuable guide. Generally you must have a depression or scar before you trephine. Sometimes, when the bone has not been injured, the trephine has proved to be of great benefit. In our second case, although I think that the symptoms are due to pressure, I am unable to locate its seat.

In the third case, his condition is certainly predisposed to it: insufficient body-weight, in proportion to his height and age; he has positive anæmia, and a want of actual muscular strength combined with a constant irritability—a muscular restlessness; his feet and hands are cold, his pulse weak, the tongue coated, bowels irregular; the food is not properly assimilated; the urine gives evidence of this, by being constantly charged with the phosphates.

Perhaps some of you may remember that I showed you last spring a case of epilepsy, with gastric aura, in an anæmic, thin, weak young man. He had received a heavy blow on the back, and he had begun losing ground; his health was impaired, and he became epileptic. His family were all remarkably weak. His brother had just recovered from incipient phthisis; his sister had chorea; his father was in bad condition. Placing him in bed, on a rigid milk diet, beginning with small quantities of milk, gradu-

ally increasing it until he took three quarts per day, he appeared to be absolutely cured. He gained thirty pounds during that period, and is now a well, vigorous, and hearty man. Since February 13th he has had no epileptic seizures. The only thing medicinal he took was minute doses of nitrate of silver, which were given him for its action on the gastric mucous membrane, as he was suffering from gastric catarrh.

Sometimes it is necessary to change the individual's whole mode of life. Total change of climate will sometimes cure our patient, when combined with suitable diet, etc.; but rest in bed is one of the most useful means, together with a most radical and rigid diet, until we get the system purified, and then we may increase the diet. Such a treatment works a change in the molecular and chemical conditions of the body, and so we get some of the most complete recoveries, not only from this disease, but also from a very large number of chronic diseases.

This lad (Case III.) has been in bed for two weeks, and in that time he has gained four and one-half pounds. He has been taking nothing but milk, a little mush, and a small amount of phosphoric acid.

He now weighs ninety-six and one-half pounds. I will keep him in bed on his present diet until he weighs one hundred and twenty pounds, and then will send him to a different climate. Before he had been put on this treatment, he had been taking bromide of potassium, with the result of making him more anæmic.

In the second case, I also consider that a treatment involving a great deal of rest, and a very radical and rigid diet, is of the utmost importance.

Suppose there is a thickening of the membranes, and we do not know it, and these infernal attacks are continually occurring, and we keep on with our remedies—those of which so much has been said—as the attacks grow more frequent; the bromides are given in larger doses, yet they do not control the fits; then we must discard such measures, and place him on a rational treatment. I do not wish to say that the bromides are not to be used; undoubtedly, they are of very great importance. They have entirely changed the face and treatment of epilepsy, but too often we drop all other remedies for the sake of this one drug. Too often do we push the bromides to the stage of bromism, and at last the constant state of depression is worse than the epilepsy. At last, no amount of the bromides, even if given to the extent of an ounce or two a day, will control the excitability of the cerebro-spinal axis.

There are some men—men who live, not in the large cities, but in obscure, almost unknown country towns—who have great reputations from having cured large numbers of epileptics. When asked to send prescriptions they never do it, but require the individual to come to them. The country air and the surroundings are undoubtedly the chief agents on which they rely. Their secret remedies always prove to contain the bromides. Large sums of money have been paid by governments and states for the secret of the noted preparation, and always the most conspicuous remedy has proved to be the bromide, combined perhaps with an antispasmodic, as valerian or asafœtida. The secret of their cure lies more in the hygienic surroundings which they insure for their patients than in any medicine which they profess to give.

There are certain indications which call for the use of the bromides. After we have done what we can by hygienic measures and the like, and find that we cannot control the attacks, then the bromides will relieve our patient greatly, causing the fits to be slight and infrequent.

In cases like the second, where there possibly is some active inflammatory element, after we enforce a radical course of hygiene, and the system is in good condition, he will be placed on the bromides, with a fair prospect of good being derived from them. If the epileptic seizures are the result of sunstroke, we should give the mild chloride of mercury and potassium iodide.

In the third case the calomel and potassium iodide, if given in small quantity and for a long time, may give great relief. In the second case we may also use nitrate of silver with great benefit. A second set of cases where this drug has proved of great relief to epileptics are those in which the fits were caused by a morbid irritability of the mucous membrane of the stomach. It has also proved of immense service where there were irritations about the brain of a removable character.

All the cases of nitrate of silver poisoning which I have seen were in epileptic patients. In order to avoid this unfortunate occurrence, we intermit treatment for a week or two. As I have frequently noticed, nitrate of silver, when given for some time, causes a blue line on the gums. If the treatment is then persisted in, the blue skin will make its appearance. This blue line is a perfect guide in the administration of the silver salt. As soon as the line shows itself the remedy should be immediately discontinued.

In the second case, I will put him at rest on a radical diet, with nitrate of silver; I will have his head shaved, and again see if I can find anything. In addition to these remedies, we find other cases where general tonics are particularly important. Thus, large doses of iron have been in some cases of especial benefit.

### Service of HERBERT KENDALL, M.D.

### SARCOMA OF SPLEEN.

Michael R——, American, thirty-three years of age, a painter by occupation, was admitted to Cook County Hospital, April 22, 1881. Family history shows no hereditary tendencies to disease. Patient always enjoyed excellent health until four years ago, when he had a "malarial attack," lasting about three weeks, which, however, was not of a severe type, as he continued working at his trade. Made a good recovery with drachm doses of coal-oil, taken three times daily for treatment. Since that time until present illness commenced he has enjoyed the best of health. Has been living in a malarious district of Mississippi. Six weeks prior to admission, began to be troubled with cephalalgia, malaise, and constipation; the latter was obstinate, would not yield to cathartics. Very soon he began to complain of soreness and pain in the epigastric and left hypochondriac regions. Pain was constant and of a dull, aching character, aggravated when lying on the right side; somewhat relieved when walking, or when pressure was made. During the first week of his trouble he noticed a swelling in the left hypochondriac and lumbar regions. The above-described symptoms continuing, patient thought a change of residence might be beneficial, and came to Chicago four weeks ago. Gradually getting worse, four days prior to admission he was obliged to stay in bed

altogether; previous to that time had been able to be about the house a part of the day.

*Admission.*—Dorsal decubitis. Presents an emaciated, cachectic appearance. Face has an anxious expression, as of one having suffered acute pain. Says he has been unable to sleep for five or six days. Has a short, hacking cough. Appetite is poor. Has been taking fluid food only. Tongue has a thick, brownish coating. Bowels obstinately constipated. Patient is irritable, easily disturbed by noise. Complains of severe pain in the left side. Temperature, 102.8°. Pulse and respiration augmented. By physical examination, find heart, lungs, and area of hepatic dulness, normal. Find a hard, nodular tumor occupying the left hypochondriac and lumbar regions, extending from mammary line of sixth rib to inguinal region. Patient was given sufficient morphine hypodermically to relieve pain; ten grains of quinine, and ordered,

℞. Ferri. sulph.,
Quiniæ sulph.,
Ext. hyoscyami..... ãã grs. xxx.
Mass. hydrarg.,
Aloes pulv.,
Ext. nucis vom..... ãã grs. xv.
M. ft. pil no. lx. Sig.—Two pills three times daily.

The following morning temperature was 100.2°, pulse 102. Evening: temperature 102°, pulse 108. Was again given ten grains of quinine and sufficient morphine to produce sleep. From this time on his temperature ranged from 99° to 101°, never getting as high as 102. There was no material change in patient's condition until May 1st, when he commenced having diarrhœa. Had four or five semi-fluid, brownish colored passages daily.

May 2d.—Dulness found to be extending upward. When in sitting posture, percussion-note flat as high as fourth rib on left side; about the same on right, line of dulness varying with position. Hypodermic needle being introduced in axillary line, between fourth and fifth ribs, a bloody serum was withdrawn. Patient began to complain of dyspnœa.

May 3d.—Fluctuation was detected in tumor just below cartilages in mammary line, and pus withdrawn with the hypodermic syringe. It was thought to be an abscess caused by hemorrhagic infarction, and it was decided best to make an opening and provision for free drainage.

May 5th.—An incision one and one-half inches in length was made, parallel to and just below the seventh costal cartilage. After the dissection had been carried through the abdominal wall, about two ounces of pus and sloughed tissue escaped. The finger introduced through the wound entered a cavity about the size of a Havana orange, surrounded by soft, sloughing tissue. The cavity was washed out with a five per cent. solution of carbolic acid, a large drainage-tube introduced, the wound partially closed, and dressed à la Lister. The discharge was quite profuse, and the wound was dressed daily. The diarrhœa could not be checked. Dyspnœa increased, and caused a great deal of complaint from patient. Gradually became weaker, and died the morning of the 10th. For forty-eight hours before death, complained of severe abdominal pain, lay on his back with legs and thighs flexed.

*Post-mortem examination*, twenty-four hours after death.—Two ounces serum in pericardial sac. Heart normal. Sixty ounces bloody serum in each pleural cavity. This amount of serum, with the space occupied by the tumor, had caused entire collapse of left lung. Right lung in a normal condition. Abdominal cavity contained sixteen ounces sero-purulent fluid. Peritoneum injected. Omentum thickened, and with adjacent abdominal viscera adherent to spleen. Spleen nodular and very much enlarged. Anterior surface adherent to abdominal parietes. Measurements were: eleven inches in length; five inches lateral, four and one-half antero-posterior. Cut section showed a large number of tumors about the size of a walnut, some larger, some smaller, yellowish-brown in color, of firm texture, having no line of demarcation or sign of retrograde metamorphosis. In the upper anterior part of spleen was the cavity into which the opening had been made; it had enlarged a little subsequent to the operation, and was surrounded by soft, brownish, sloughing tissue. In the lower part of the spleen was another smaller cavity, about as large as a hen's egg, the walls of which had ruptured and allowed the contents to pass into the abdominal cavity. By microscopical examination the tumors show the structure of sarcomatous tissue. Liver slighty enlarged, otherwise normal. Kidneys normal. A few abdominal lymphatics enlarged.

## Progress of Medical Science.

Some New Points Concerning the Sympathetic Nerve.—In 1851 Claude Bernard first observed flushing and elevation of temperature in the ear, after section of the cervical sympathetic, stimulation of the nerve having the opposite effect. Later his experiments were verified by Brown-Séquard and many others. It has been customary since then to regard the sympathetic as a vaso-constrictor nerve. And all vessels were supposed to be provided with filaments proceeding from that main trunk.

Recently, Morat and Dastre (*La Scuoala Medica Neapolitana*, Nos. 11 and 12, 1880) instituted a series of experiments relative to the sympathetic. Their work was done under the supervision of Chauveau, at Lyons. They found that stimulation of the cervical sympathetic produced blanching in some parts, and vascular turgescence in others. The pallor was associated with a retarded flow of blood, and the flushing with increased force of circulation. The latter was noticeable about the lips, cheeks, and buccal mucous membrane.

The authors, therefore, rightly concluded that the sympathetic contained vaso-dilator in addition to its vaso-constrictor fibres. Hitherto the chorda tympani has been regarded as the one vaso-dilator nerve. Investigators have sought for other nerves of this kind among the cerebro-spinal branches, where none exist. The sympathetic was, in the same manner, assumed to be the vaso-constrictor nerve *par excellence*, and was not examined with regard to any possible vaso-dilator properties it might possess. Now, Dastre and Morat found both kinds of nerves in the sympathetic. But there remained to be explained the reason why only a single set of muscles, such as is found in the vessels, could be controlled by two different kinds of nerves. This apparent anomaly was explained by the fact that the vaso-dilator nerves did not terminate in the vascular layer of muscle, but reached for a shorter or longer distance beyond the vessels. These dilator nerves could be traced to the neighboring ganglia, or else were lost in adjoining nerve-plexus. The dilator nerve of the ear was

distinctly seen by the authors. Until now, it will be remembered, only vaso-constrictor auricular branches had been discovered. From this, and similar facts, it would appear that the sympathetic is a mixed nerve as regards its vascular relations. The newly discovered nerves inhibit the action of the vaso-constrictor fibres. The centres of regulation for this delicately-poised double action are found in the ganglia of the sympathetic. Thus the sympathetic must be regarded as presiding over the circulation of blood in the body, regulating both constriction and distention of the vessels, and at the same time serving as a vaso-motor trophic nerve.—*Allgemeine med. Cent.-Zeit.*, March 30, 1881.

THREE CASES OF HEPATOTOMY. — Lawson Tait's paper on Hepatotomy, read before the Royal Medical and Chirurgical Society (*Lancet*, May 28, 1881) contained the narration of three cases in which the author performed operations on the liver similar to those in two cases already received by the society. Abdominal section was performed, and the liver was found not to be adherent to the parietes in any of them; the contents of the tumors were removed, and the edges of the wounds in the liver were stitched by continuous suture to the edges of the wounds in the abdominal walls, and drainage-tubes were fastened in. Two of the cases were operated upon for hydatids of the liver, and the other for a large cystic abscess enclosing a loose piece of liver-tissue, weighing about an ounce, and which had apparently been a slough. All three patients made good recoveries, and were, at the time of reading the paper, in perfect health. Mr. Tait said that the results of his observations had been such as to lead him to prefer abdominal section to aspiration in all cases of hydatid disease of the liver. The hemorrhage from the liver was readily stopped by pressure. There was some difference of opinion as to the treatment of unilocular hydatids; but his own experience, and that of others, especially Styrian surgeons, led him to believe that aspiration rarely succeeded in producing permanent cure. Tapping removed the fluid, but did not prevent the cyst from again secreting. The prevention of the escape of the contents of the cyst into the abdomen was principally due to the manual dexterity of his assistant, who seized the cyst with forceps and held it up—a sponge being at the same time applied to each side of the wound.

REPEATED PARACENTESIS IN THE ASCITES DUE TO CIRRHOSIS OF THE LIVER.—The value of early and repeated paracentesis in the ascites due to cirrhosis of the liver is exemplified by a case which came under the observation of Dr. W. A. Duncan (*British Medical Journal*, June 4, 1881). The patient was a retired naval officer, aged forty-six years, who had always been a moderate drinker, taking on an average one or two glasses of rum daily. The ascitic fluid gradually accumulating, paracentesis was performed and seventeen pints of straw-colored serum were removed. Previous to the operation there had been no dyspnœa nor œdema of the legs, and but little discomfort. No bad result followed. Subsequently the operation was successfully performed twenty times in the interval of ten months, when at the expiration of that period there was no reaccumulation of ascitic fluid and the general condition of the patient was markedly improved. In all, one hundred and seventy pints of ascitic fluid were removed, as much as twenty pints being drawn at one sitting.

EXCISION OF BREAST IN INTRACTABLE ECZEMA OF THE NIPPLE.—At a recent meeting of the Clinical Society (*Lancet*, June 4, 1881), Mr. George Lawson exhibited a breast, which he had removed on account of long-standing eczema of the nipple. The case had resisted all treatment for twelve months, and was extending. Feeling that the usual termination of such cases was diffused cancer, Mr. Lawson advised, and accordingly removed the breast. There was a red, scaly patch, raised slightly above the level of the skin, and extending for about two inches around the nipple. The breast, when examined, exhibited cancer-elements diffused throughout the organ. Mr. Lister thought the line of practice a serious one, if meant to apply to all cases of eczema of the nipple, and would hesitate about advising the removal of the whole breast. But he was not long ago consulted by a lady for eczema of the nipple, which he treated by local applications, and since then he learned that cancer had developed. Mr. Lawson said that he advocated excision in cases where eczema of the nipple had resisted all treatment.

RETRO-PHARYNGEAL GOITRE.—These tumors, according to Madelung (*Langenbeck's Archiv*, vol. xxiv., part 1), are usually not associated with enlargement of the thyroid gland in its normal situation, and under such circumstances they may readily be mistaken for retropharyngeal abscess. This error is less likely to occur when there is a simultaneous enlargement of the thyroid gland proper. In the former event the retropharyngeal tumor is probably encapsulated, and an incision would not be likely to do much damage. Indeed, the tumor might be enucleated, as has been done with success by Czerny (*Beiträge zur operativen Chirurgie*, 1878). In the latter event a free incision might give rise to dangerous hemorrhage, while the attempt to extirpate would be a formidable undertaking, as are all partial excisions of ordinary goitres. Chiari reports three cases of retropharyngeal goitre, all associated with considerable hypertrophy of the thyroid gland. They had each given rise to great interference with respiration and deglutition. In the first case, the pharyngeal swelling was supposed to be a retropharyngeal abscess; an exploratory incision was made, giving exit to a moderate amount of blood. Parenchymatous injections of tincture of iodine into the substance of the tumors caused considerable shrinkage of the latter, with great subjective relief. The second patient refused operative interference. In the third case parenchymatous injections were productive of no benefit.

As regards treatment, Chiari divides these cases into two categories, viz.: those in which the retropharyngeal goitre is completely encapsulated, and those in which it is continuous with the remainder of the thyroid gland. In the former event it is probably possible to remove the accessory goitre, either by way of the mouth or from the outside; in the latter case no such operation should be attempted. Here parenchymatous injections of tincture of iodine are usually followed by some improvement. But they should be cautiously performed in view of the already existing obstruction to respiration, any slight exaggeration of which might give rise to such symptoms of suffocation as to demand immediate catheterization of the larynx. If this were not followed by instant relief, tracheotomy (under these circumstances a very difficult operation) would have to be at once performed.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 30, 1881.

## HAS OUR VACCINE-LYMPH DEGENERATED?

SMALL-POX has now a rather unusual prevalence, both in this country and in Europe. In the United States there have been, on the average, two or three hundred cases every week for a number of months past. The chief centres of the disease have been Philadelphia, New York, and Chicago. Across the water it prevails still more actively, especially in London, Paris, Berlin, and Vienna. In the former city there were, in the week ending May 21st, 1,390 cases, with 103 deaths, which almost constitutes an epidemic. An equal, if not larger, proportionate number of cases have appeared in Philadelphia.

These facts have aroused a great deal of attention from various quarters as to the protective value of vaccination. An important contribution to one side of this subject was made, not long ago, by Dr. Charles Cameron, M.P. He propounds the question: Does vaccination, as practised in Great Britain, afford as much protection from the subsequent occurrence or virulence of small-pox as it did in the days of Jenner? and he answers the question decidedly in the negative. It may be imagined that such a conclusion would be difficult to prove with any degree of positiveness, though it has long been felt to be the fact by many experienced observers. In 1857 a commission, appointed by the Belgian Academy of Medicine to inquire into the matter, reported as one of its conclusions: That humanized vaccine becomes gradually enfeebled through its successive transmissions, without, however, altogether losing its preservative power. About the same time Dr. Simon published a report giving a similar opinion. These reports, however, were based partly on insufficient evidence and partly on theoretical reasoning. And we have, on the other side, the opinions of many persons whose experience in vaccination has been very large.

But Dr. Cameron has now collected more evidence, in the way of statistics, to support his view than has ever been presented before, and his arguments therefore command especial attention.

It is known that Jenner believed the preventive power of vaccination to be almost absolute. And there is a good deal of evidence that in the first fifteen or twenty years after vaccination was introduced the cases of post-vaccinal small-pox were very few.

It was not until 1819, however, that statistics of any great value began to be accumulated. In that year an epidemic of the disease was recorded in Scotland. After this, observations on a large scale were made both in that country and in France, Switzerland, Sweden, and Copenhagen. Grouping all of these cases of post-vaccinal small-pox, except those of Sweden, which are not exact, we find that the total number up to the year 1836 was 15,186, with a mortality of 266, or 1.75 per cent.

A second group of statistics was collected by Dr. Marston in the London Small-pox Hospital. His figures cover the years from 1836 to 1852. Among 2,787 cases of post-vaccinal small-pox the mortality amounted to 6.9 per cent. Among 10,398 cases of a similar kind, occurring between 1852 and 1867, the mortality was 7.6 per cent., that among the unvaccinated being 35.7 per cent. In the last decade, 1870–79, among 15,000 cases the mortality advanced to 9.2 per cent.

A table will show this better:

PERCENTAGE OF MORTALITY IN CASES OF POST-VACCINAL SMALL-POX.

| 1819–35 | 1836–52 | 1852–67 | 1870–79 |
|---|---|---|---|
| 1.75 | 6.9 | 7.6 | 9.2 |

The above statistics attempt to prove, of course, only the diminished power of vaccination to lessen the malignancy of small-pox.

It may be said that the statistics do not include enough cases to prove the point.

It may also be urged that the vaccination was done less efficiently; and finally (as appears to be the fact), that the disease itself has grown more malignant of late years. Against the second objection Dr. Cameron shows that even when comparisons are made between successive groups of post-vaccinal cases having one, two, three, or four cicatrices, the evidence of an increased mortality is the same. Thus, for example, the mortality from post-vaccinal small-pox with four cicatrices was in 1836–51 one and one-tenth per cent.; in 1870–79 it was four and eighty-three-hundredths per cent.

Against the third objection, it is shown by a number of statistics that the ratio of mortality in post-vaccinal small-pox has had a greater increase, proportionally, than has the mortality among the unvaccinated cases. Thus, while the ratio of mor-

tality has increased in the present century from twenty-five or thirty-eight per cent. to forty-five per cent. in the unvaccinated, the mortality in the vaccinated has increased from one per cent., previous to 1830, to about ten per cent. in the last decade.

Vaccination, as is well known, acts in two ways. It prevents small-pox and it lessens the virulence of the disease, if subsequently taken.

The statistics so far given cover only the latter point. It is much more difficult to obtain any certain data regarding variations in the power of the vaccine lymph to ward off variola altogether. Some facts, however, bearing on this part of the subject have been collected. Jenner thought that one vaccination was in general a sufficient protection for a lifetime. The records of the earlier part of the century seem, to Dr. Cameron, to justify Jenner's confidence; but the necessity of revaccinations became in course of time very apparent, and we can hardly avoid the belief that it is necessary now to revaccinate at shorter intervals than formerly. The following table seems at least to indicate very strongly that many more cases of post-vaccinal small-pox occur now within ten years after a vaccination than occurred in the first half of the century. The statistics are from English hospitals.

| Period. | Ratio of cases of children of ten and under to total cases of post-vaccinal small-pox. | Ratio of deaths in children of ten or under to total deaths from post-vaccinal small-pox | Number of observations on which percentages are based. |
|---|---|---|---|
| 1824-51.. | 2.4 | 2.7 | 6,187 |
| 1870-9... | 12.4 | 11.3 | 11,822 |

Even taking into account, therefore, the fallibility of statistics and the necessary incompleteness of some of those here presented, it seems to be very probable indeed that the humanized vaccine, as used in England, has degenerated.

As regards that used in this country, nothing so positive can be said. The virus that we have here is partly the pure bovine and partly the humanized. Most of the former and part of the humanized lymph comes from the Beaugency stock. There is getting to be an increased confidence in and a much wider use of this animal virus among American physicians. It is used almost exclusively in this city. Still it cannot yet be said that it has not lost or is not losing any of its power. It is now fifteen years since it began to be propagated, and nearly eleven years since it was introduced into this country. Two years after its introduction, Dr. Martin stated that four hundred thousand vaccinations had been performed with it, and that no case of post-vaccinal small-pox had occurred.

With regard to the humanized virus, its quality doubtless varies in different localities. Some time ago we mentioned the opinion of Dr. Atlee, of Lancaster, Pa., which was that in an experience of over sixty years he had seen no deterioration in the humanized virus. The experience of our city health board during the past six months has shown that the virus used here, which is the bovine, is most efficacious. Nearly all the cases of small-pox have occurred either in the unvaccinated or in those who had not been vaccinated since infancy.

Whether or not the American lymph has degenerated, it seems quite clearly shown that such virus can degenerate; and this fact is a most important one for the sanitarian and physician to bear in mind.

---

### PHYSIOLOGY AND MATERIALISM — SOME NEW PHILOSOPHICAL VIEWS.

It is undoubtedly the tendency of scientific studies to incline the mind toward materialism; and it often happens that, in time, a person thus studying finds himself unable or disinclined to accept any facts whatever until their truth has been scientifically and exactly demonstrated. Whether this be a misfortune or otherwise, it is true, as many medical men who seriously pursue their profession can testify.

A work appeared in London not long ago which aimed to apply demonstrative reasoning to a number of things usually considered rather outside of such a process, and which contains also some novel physiological theories that are not without interest. The book has the rather oppressive title: "An Inquiry into the Process of Human Experience." Its author, Mr. William Cyples, lays large claims both to original observations and explanatory hypotheses.

Three of these hypotheses we wish to refer to, because they are chiefly physiological, and have an interest in themselves apart from any anti-materialistic inferences to be drawn from them.

Mr. Cyples asserts that by a careful study of the mental and physical changes in himself and others, while in conditions of reverie, attention, etc., he has made out a new law in regard to the reception of sensuous impressions. It is this: that no one of the senses can operate so as to arouse the consciousness, without the associated working of the muscular machinery connected with such special sense. Thus, he says: "Fix the eye, and if you do it completely, you cease to see; give over altering pressure, and the sensation of touch stops." Perfect rest of the muscles connected with the different senses, no matter how slight or momentary it may be, arrests experience in respect of that sense. The power of concentrating the mind, of attention, in any individual, means that he has acquired the power of controlling this coincidence in activity between any sense and its muscular machinery. When this machinery works inharmoniously with the excitations of sense, or when it is suspended, there is

more or less loss of consciousness. He would thus explain the influence of narcotics, and the mechanism of sleep, swooning, etc.; though this disassociation, or inco-ordination, would be, of course, only one factor in these latter phenomena.

We have here, then, an assertion, which, put in physiological language, would be, that the activity of the kinæsthetic centres is necessary for the conscious awakening of the visual or other special sense centres. That these centres do act together very closely is acknowledged. But their absolute interdependence seems improbable, and is not demonstrated by Mr. Cyples. We have, however, but hinted at the theory, and cannot attempt to give the author's own elaborate defence of it.

His second theory, which is also based on original observations, is one which aims to explain the consciousness of pain. The prevailing views of modern psychologists, such as Bain and Spencer, regarding the phenomenon of pain, are that it is the accompaniment of an abatement of vitality. Modern physiologists explain it by assuming that in pain there is an excessive stimulation of the nerve-fibres, and that, in consequence, the nerve-impulses engendered overflow their natural paths; they inundate, so to speak, other tracks, and excite an abnormal number or kind of sensory areas.

Mr. Cyples essays to refute the theory which assumes an abatement of vitality. His own view is that pain arises whenever a group of nerve-cells and their connecting fibres become disintegrated by a too great or prolonged excitation. Thus, let the arm be held out at a right angle. In a short time there will be a sensation of fatigue, then of pain, and at last of real agony. This progressive change in the sensations is brought about by the gradual disintegration of the nervous tissue that made up the co-ordinating and controlling centre for the arm-muscles.

The deductions from this theory are chiefly of psychological interest. According to it, the consciousness is more active and intense the less the physical subtratum for it. "Pain," he says, "may be said to be the first protest which consciousness makes against its own dwindling." If, according to the materialistic view, mind only exists in quantity proportionate to the nervous matter with which it is associated, how can there be pain? In fatigue and in pain, while nerve-tissue disintegrates, mind, "the egoistic experience," is intensified.

We have already wandered too far from what is strictly medical, and we can only make a bare reference to a third hypothesis, or rather line of reasoning given by the author in question. This is a most curious and ingenious attempt to demonstrate, from physical and physiological data, the existence of the will. His views certainly deserve the attention of the modern philosophers if for no other reason, because they are presented with such care and in such strict accordance with scientific methods.

Whatever may be the actual truth of Mr. Cyples' views, physiological or psychological, they are acknowledged to represent one of the best contributions to modern psychology—which means a psychology based on physiology—that has been made for many years.

---

### THE PRESIDENT.

THE new complications in the President's case, which have occurred in the past week, aroused fresh anxiety concerning him, and justify us in continuing our record of his condition.

The improvement which was going on at our last writing continued with scarcely any change until a week ago. The temperature every morning was normal. In the afternoon there was a slight rise, but it did not reach 100° F. until Friday, the 22d, when it stood at 100.2° at 7 P.M. Later in the night it rose a little higher, and the patient passed a somewhat restless night.

On Saturday morning, at 7 A.M., the temperature was normal, as usual. Half an hour later, however, a slight chill occurred. The temperature then rose steadily, until at about eleven o'clock it was 104°, the highest point reached since the wound was inflicted. A second chill came on at this time. The patient vomited also. But a free perspiration soon followed, and the fever again declined until, in the evening, the temperature was 99.2°. At midnight another slight chill occurred, and the patient's sleep was a disturbed one. Still, in the morning the temperature was normal again.

At this time, Drs. Agnew and Hamilton having arrived, a consultation was held. The attending physicians had observed that the pus had flowed less freely for the past two days, and had naturally laid the chills and pyrexia to an accumulation of purulent matter with septic absorption.

This was found to be the case. The pus had burrowed down below the opening of the wound and behind the eleventh rib. Here it had accumulated. Local anæsthesia was used and an incision made about three inches beneath the original wound. There was an escape of pus as had been expected.

A drainage-tube (which for some reason the daily press has christened a drainage-pipe) was passed through the two openings and the wound was thoroughly cleansed.

The operation was slight and painless; the great fortitude ascribed to the President in not wincing is not so remarkable, therefore. Good symptoms immediately followed, and at evening the temperature was only 99.2°. On the 26th the new opening was enlarged, and a small spicula of bone removed. Improvement has, up to date of writing, steadily continued.

# Reports of Societies.

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, May* 5, 1881.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

### PROGNOSIS AND TREATMENT OF PLEURITIS IN CHILDREN.

DR. J. LEWIS SMITH read a paper on the above subject, it having been referred to the Academy from the Obstetric Section. (See vol. xix., p. 413.)

DR. C. E. BILLINGTON remarked that little remained to be said after the exhaustive paper on the subject by Dr. Smith; but he would say, in relation to the case with which his name was connected, that there was strong evidence that the injected carbolic acid solution penetrated the pulmonary pleura and entered the lung, for it flowed out less freely than on a former occasion. There was an odor in the child's breath, a moist cough developed which had not existed before, and the child went into collapse. He had reported a case not many years ago, in which he introduced the trocar at a point where an external opening was about to form spontaneously, and syringed out the pleural cavity repeatedly. The pus, however, became putrid, and on the third or fourth day the child began to suffer from extreme dyspnœa, and coughed up carbolized water which had been used as an injection. This occurred a number of times without any alarming symptoms, until on one occasion the child passed into extreme collapse. Artificial respiration was resorted to, as in the case just alluded to, and the child was resuscitated; but it was probable that such an accident might sometimes prove fatal.

DR. BEVERLEY ROBINSON'S experience with pleurisy in children was more limited than with the same disease in adults; but the remarks which he wished to make might apply to either class of cases. The occurrence of œdema of the lung influenced the prognosis unfavorably, and he believed it occurred most frequently after the artificial removal of the effusion. This fact, he thought, added to the importance of not drawing off all the fluid at one time, especially if the quantity were large. He believed, from an examination of the statistics three years ago, and from observation since, that thrombi and sudden death occurred perhaps never during the operation of paracentesis, but rather during the washing out of the cavity after a larger puncture had been made. He did not think that there was any evidence to show that the inflammation of the pleura was increased by the former operation, or that any serious results attended it; and it was his rule, therefore, after detecting fluid, of whatever kind, by the exploratory puncture, to perform paracentesis, especially if the effusion were considerable. He thought Dieulafoy had proven conclusively that the use of the aspirator at any place was not dangerous. Dieulafoy had stated, also, that the puncture of the lung, which sometimes occurred accidentally during aspiration, was not attended with danger; on the contrary, that he believed the local bleeding which it caused was beneficial. Dr. Robinson was not prepared to accept the latter statement, but he believed that the accident was not necessarily injurious, especially if the puncture were made with a small needle. He had treated two cases of empyema in adults within the last year and a half, and one patient, whose pleural cavity was thoroughly irrigated, died; the other, who was under his care only a part of the time, and in whom irrigation, he believed, was not practised at all, got perfectly well. The fact that fatal accidents do sometimes follow irrigation, and never, he believed, aspiration, rendered it important to adopt irrigation with care. Post-mortem examination showed that the cause of death in different cases could be attributed to different things—as thrombi, either of the heart or pulmonary vein, or emboli, etc.—conditions which, perhaps, could not be directly attributable to either aspiration or irrigation. He found it impossible sometimes to withdraw fluid, although its presence had been established beyond doubt, and no apparent explanation, as stoppage of the tube or the presence of adhesions, could be offered for it. He did not believe there was any medicinal means for aborting, arresting, or notably arresting the march of the pleuritic effusion after it was once established. Aconite and quinine, except in small doses, had a depressing influence upon the heart's action, and should not, he thought, be given to control the inflammation in these cases; digitalis, on the contrary, not only reduced the pulse and the respirations, but also sustained the heart's action, and was the drug that should be used.

DR. KINNICUT did not think that a lack of displacement of the heart was necessarily an indication that paracentesis was not called for in simple pleurisy with effusion. He had observed, in some cases of pleurisy with effusion on the left side, that the apex-beat was in its normal position, the explanation being that there was adhesion between the pericardium and the pleura. A case was reported by Dr. H. T. Smith in which the heart-beat was to the left of the normal position, although there was considerable effusion in the left pleura. He believed in irrigation in empyema. In the case of a young boy, a free incision was made, and pus ran out freely, after which daily irrigation was practised. If for any reason it was omitted, the temperature would rise, and symptoms of sepsis develop, which would disappear on renewing irrigation. This was experienced repeatedly. The same was true in another case under his care in St. Luke's Hospital, and the patient finally recovered. He referred to a case reported in the London *Lancet*, in which an English surgeon so arranged an apparatus as to keep up constant irrigation, operating automatically with the inspirations and expirations of the patient. The fluid used was Condy's. He thought that a simple serous effusion, although it did not produce any marked dyspnœa, but which did not decrease in quantity, should be withdrawn within three weeks, because of its tendency to become purulent.

DR. A. A. SMITH said that, as a student and practitioner, he had often had occasion to feel thankful to the author for his valuable instructions on the diseases of children, and he would now express his thanks for the very valuable paper which had just been read. He thought more danger attended the operation of paracentesis thoracis than Dr. Robinson would have us believe, and the possibility of puncturing the lung tissue, an accident which Dr. Robinson considered of little moment, was in itself a matter for careful consideration. A simple serous effusion, if allowed to remain in the pleural cavity sufficiently long, tended to undergo purulent change, and the liability thereto was greatly increased by the addition of even only a small amount of blood. In

more than one case in his practice, in which there was only a simple serous effusion, as evidenced by the microscope, after a few operations of paracentesis thoracis pus-cells began to appear, and the cases resulted in empyema. Again, he thought there was always some danger of the entrance of a little air, which, of course, increased the chances of empyema; and danger, also, of puncturing blood-vessels which had formed in the inflammatory material, as well as those of the lung-tissue, and, consequently, the escape of blood into the fluid, which would favor purulent change. He thought that jaborandi, when given in small doses, acted as a cardiac stimulant, not as a depressant, and in many cases as a diuretic, not as a diaphoretic, and prompted absorption of the effusion, and was therefore indicated in pleurisy. He had known it to check profuse sweating. It should be given to children in doses of from one to three minims of the fluid extract, repeated in from one to six hours. He thought that, in some cases in which there was great dyspnœa with high temperature, the withdrawal of some fluid was indicated, although the pleural cavity was not full. He thought sufficient stress had not been placed upon the fact that the removal of only a small quantity of the fluid effusion promoted absorption, and he referred to the case of a child in which tonics and slight counter-irritation failed to promote absorption at all, but absorption began to take place immediately after the removal of only half a syringeful of the effusion; and this occurred frequently in other cases in which a syringeful was withdrawn. He referred to the fact that air which entered the pleural cavity rose to the top, and he had detected its presence by percussion after the closure of the opening through which it entered, and proved afterward by percussion that it must have been absorbed. He did not fear the entrance of air so much as formerly. Iron, quinine in small doses, cod-liver oil, and tonics in general were indicated, and, if necessary, the heart should be sustained by alcoholic stimulants; it was particularly important to keep the digestive system in the best possible condition. In performing paracentesis thoracis the puncture should be made, not too far back, but forward of a line perpendicular to the axilla.

The President, for some years past, had deputized the care of such cases to his assistants, but in former years he had a great deal of faith in certain therapeutic measures, as follows: certain effects of the presence of the effusion were to be avoided, or relieved if possible, such as pain and disturbance of nervous function and arterial excitement. These were important indications, as imperfect oxygenation, to which they led, had a very unfavorable influence on the progress of the disease. The first case of the kind which he had occasion to treat, and which led to a very thorough study of the subject at that time, occurred in his own child, about eighteen months old. As just said, the two chief indications were the relief of pain and the control of arterial excitement, and the agents referred to by those who had preceded him, for the control of cardiac excitement, were aconite and digitalis; but he considered veratrum viride far more efficient. It did not cause the secondary depression which sometimes followed the use of aconite, nor did it neutralize the effects of stimulants as did aconite; and it was more certain in reducing the frequency of the pulse than was digitalis. His child had all the signs of a severe attack of pleurisy. He administered one drop of laudanum and one of the tincture of veratrum viride in a teaspoonful of sugar and water, repeating every hour; applied a poultice over the affected side, and covered it with oiled silk. As the pain became relieved he decreased the quantity of laudanum, giving one drop of laudanum every two hours, and two drops of veratrum every hour; he then increased the veratum to three drops, until the pulse was reduced from where it could scarcely be counted to one hundred per minute. The relief given was very marked. This was before the time of the thermometer, and the temperature, consequently, could not be given. There were indications for calomel and nitrate of potash, which he gave. He had often adopted this plan of treatment, and had found it very efficient; it diminished the severity of the symptoms and relieved suffering and nervous disturbance.

The Academy then adjourned.

## CHICAGO MEDICAL SOCIETY.

*Stated Meeting, April* 18, 1881.

Dr. E. Ingals, President, in the Chair.

### VACCINATION AND VACCINE VIRUS.

Dr. N. S. Davis opened the discussion of this subject by inquiring whether nursing children under two or three months of age were liable to take small-pox, and whether infants should be vaccinated. He once had to treat a mother for varioloid, who nursed a baby six weeks old. This baby was vaccinated twice, but without any result, and although it slept by the side of another child who had small-pox, it did not take the disease. An old man had confluent small-pox in the winter of 1856, during a variolous epidemic. There was a baby four weeks old in the house, whom he vaccinated three times unsuccessfully. The baby did not take the disease. These two cases and the one following were treated with a solution of sulphite of soda and belladonna, a proportionate dose being administered to the infants three times a day out of the mixture prescribed for the variolous patients. The third instance was one in which two children had variola in one family, and a baby of the same family escaped. He made the query: Is there less susceptibility to take the disease in infants, or is the treatment with sulphite of soda and belladonna an efficient measure in such cases?

Dr. W. E. Clarke related the case of a woman who had the measles. Her nursing child did not take the disease, but, six months after the woman recovered, the child was exposed once more, and took the measles. He generally declined to vaccinate children under two months of age, because he had once a case of adenitis, and had seen other bad results follow vaccination in very young children.

Dr. O. C. De Wolf, Health Commissioner, said that in 1878 the sulphite had been used extensively, under his supervision, by the City Board of Health, and that he had found the results of no consequence whatever. Dr. Guerin had given them a trial at the Small-pox Hospital. As to the immunity conferred by vaccination, he believed it to be very satisfactory. Of several cases of children taken to the hospital, not one had contracted the disease, although fully exposed. In regard to the greater efficiency of the bovine virus, this was asserted by some and denied by others. Dr. Jones had refused to use bovine virus for two reasons: 1st, very young children are less susceptible to it than he (Dr. De Wolf) believed;

2d, because the result is more energetic, and produces a sort of dermatitis or erysipelas. As to the first question of Dr. Davis, he related a case to the point: "A mother was taken sick with variola a few days ago, who nursed a baby two days old. It was not vaccinated. It was fourteen days old to-day. Now is the time at which the eruption should come out; but the infant has just died with convulsions, probably from an overwhelming of its system with small-pox, although no symptom manifested itself before this." Had that child been vaccinated it would have lived. He had never seen a fatal case in one who had been efficiently vaccinated. The Health Department always employed bovine virus, as it would have been impossible to procure enough reliable humanized lymph to vaccinate the seventy thousand cases this last two years. There was no doubt that syphilis could be transmitted by humanized virus. He never saw, however, anything beyond dermatitis and axillary abscesses in a few cases. In three or four cases he had found a sloughing of the scab, but he thought that, as this takes place after the ninth day, the patients were well protected. He had seen some cases of that kind who were afterward exposed to the disease, but did not take it. If anything should interfere with the vaccination before the ninth day, then it might not be protective. The people who were taking small-pox in the city were mostly adults who had not been revaccinated. There were thirty or thirty-five cases then in the hospital. The mortality among them was very great. About forty per cent. of those attacked in Chicago, in New York, and in Michigan, die. The disease was not at all modified by old vaccination. Some had confluent small-pox who had many scars on their arms. Eighty-nine per cent. of the cases of secondary vaccination were successful, and he never saw a case of small-pox among these in four years. Many people were deceived, and thought they were successfully vaccinated when they were not.

Another fact was used by the Anti-Vaccination party in England. The disease had increased, as also its mortality, since the compulsory law of 1878 in that country. It was because this law related to children under school age. The increase of the disease is observed in those only that are not subject to that law.

Dr. E. Ingals asked: Would a repetition of vaccination within a few months be successful?

Dr. De Wolf had not observed any case to the point, but he related a case of small-pox in a child who had been vaccinated eight years before. Previous to 1878, vaccination certificates used to be issued in Chicago by druggists and other people who knew nothing about medicine; but since that time none but those issued by reliable physicians had been accepted by the Board of Education. This accounted for the universal protection from the disease in children under twelve years of age.

Dr. John Bartlett said that children who are not susceptible to vaccination may take small-pox; six cases of that kind had come under his observation, and Dr. Byford had observed two similar cases, where repeated trials at vaccination had failed, and the children died of small-pox.

Dr. E. Ingals said that the rule was that cases who receive vaccination with difficulty, or not at all, did not easily take small-pox. He was himself vaccinated many times, but only the first took. He was subsequently exposed to small-pox a great deal, and finally took varioloid from a case of confluent small-pox. He was very slightly affected.

Dr. C. W. Earle remarked that he had been afraid to use bovine virus on account of the greater liability for the vaccinia to be severe and complicated.

Dr. Bartlett mentioned that Dr. Freeman Knowles, of Keokuk, saw four hundred cases of syphilis in a regiment stationed there, who had received the disease through vaccination.

In answer to a question, Dr. De Wolf said that the amount of scars left by vaccination did not seem to influence the protection conferred. The Scandinavian Poles and Bohemians generally had many cicatrices; they, however, formed a majority of the cases then in the hospital, and mortality was great among them.

Dr. R. S. Hall now answered the inquiry as to immediate secondary vaccination. He saw a successful case, and had no doubt that if we should revaccinate some weeks after the first vaccination had taken, many cases would prove susceptible.

Dr. Jane E. Walton vaccinated a child, and after six days revaccinated it. Both vaccinations produced the characteristic sore.

Dr. N. S. Davis stated that immediate revaccination was the test of a successful vaccination. If it did not take the second time, it was a sufficient proof that the first was successful. This was the only test. He had investigated the matter, and found that the great majority of cases were not susceptible of a second immediate vaccination after this had been performed successfully. If this precaution was observed, not one in a million would take small-pox. The period for compulsory vaccination he placed between the age of sixteen and twenty-one, and thought the majority were safe for a life-time after that. But circumstances arose which interfered with this immunity, as typhoid and other serious diseases, sometimes a change of climate and circumstances, and revaccination should be made in those cases. If compulsory revaccination were enforced, it would stamp out the disease. All we can do is to vaccinate school-children. He had always used humanized virus until a year ago. He had never seen a case of sore arm from its use.

## NEW YORK SURGICAL SOCIETY.

*Stated Meeting, April* 12, 1881.

Dr. H. B. Sands, President, in the Chair.

### THE MECHANISM OF COLLES'S FRACTURE.

Dr. Lewis S. Pilcher continued the discussion from the last stated meeting, and said: "I take pleasure in submitting to the examination of the society the experimental specimen of fracture of the lower extremity of the radius, which I find have been preserved, of those made by me two and three years since. They are ten in number. In one the styloid process, together with sufficient of the adjacent bone to include the scaphoid articular facet, is alone torn away.

"In the second, an incomplete line of fracture runs very obliquely across the front of the lower end of the bone, distant $\frac{6}{64}$ inch from the articular edge at the centre of the bone, and running into the articulation near the ulnar facet. The eight remaining all present nearly transverse fractures at points above the anterior articular edge, varying from $\frac{1}{64}$ inch to $\frac{3}{64}$ inch. In order to secure a fixed basis of measurements for purposes of comparison, I selected the point between the scaphoid and lunar facets as the point at which the measurements should be made

in each, and from this having drawn a line parallel with the long axis of the bone to the fractured margin, the length of this line is the one recorded. On each specimen presented this line will be seen traced, and will be observed to be a fair general mean measurement of the irregular fragments which are to be compared.

"Two of these measure each $\frac{1}{4}$ inch. They are respectively the right and left wrist of the same body, and illustrate the fact pointed out by Dr. Hamilton in his remarks that an identical lesion would be produced in the two radii of the same person. The remaining specimens measure respectively $\frac{3}{4}$, $\frac{3}{4}$, $\frac{1}{2}$, $\frac{1}{2}$, $\frac{1}{2}$, and $\frac{1}{2}$ inch. A comparison of all these specimens shows that they differ considerably in the obliquity of the line of fracture from side to side, but that this line is quite uniformly straight from before backward; in other words, an irregular portion of the lower end of the bone has broken nearly squarely off in all. These fractures were all produced by extreme backward flexion of the wrist.

"These specimens are of interest from their bearing upon the arguments advanced by Prof. Hamilton at the last meeting of this society, which I beg leave to repeat, as they impressed me at the time—subject to correction, if I am wrong: 1. The insertion of the anterior radio-carpal ligament is limited to the one-fourth inch immediately above the articular surface. 2. The portion of the bone into which the ligamentous fibres are inserted alone would sustain any strain put upon them, and would be torn away by excessive violence. 3. Experimental fractures of the lower extremity of the radius by forced backward flexion, as a rule, present lines of fracture distant from the articular edge less than one-half inch. 4. Fractures of the lower extremity of the radius, as ordinarily produced by falls on the palm of the hand in the living subject, present, as a rule, lines of fracture more than one-half inch above the articular edge. Therefore, some other force than that of avulsion through the anterior radio-carpal ligament must be the determining agent of the fracture at this particular point. This force is the impact of the fall.

"I attempted, imperfectly, to call attention at that time to some sources of error in this reasoning. First, with reference to the insertion of the anterior ligament. This ligamentous insertion is not comparable, as we would infer from the manner in which it is referred to, to the fastening together of two distinct bodies, as by the tying of a rope, or the clamping of a bolt; but the structure of the one is continuous with that of the other, the ligamentous tissue being continuous with the connective-tissue framework of the bone itself. Force transmitted through the ligament is not abruptly precipitated upon the bone, but is transmitted through continuous tissue until by its mechanical arrangements it is disintegrated and expended. If a cross-breaking strain, therefore, is exerted through this ligament, the mechanical arrangement of the bony lamellæ of the extremity, the cohesion of its particles, and the position of the fulcrum, which is the fixed point upon which the strain is exerted—all variable factors—influence the result more than the particular superficial area of the apparent insertion of the ligament.

"The truth of this is also illustrated by the varying degrees of ease with which fractures of the inferior extremity of the radius are produced at different ages of life. This fracture occurs very rarely in children under ten years of age, nor can it usually be produced upon their bodies experimentally by any force. In the rarefied and brittle radii of the aged, it is occasioned by comparatively slight force. Schmit ('Fract. de l'extrém. inférieure du radius,' p. 55) found, in 48 subjects between sixty and ninety years of age, a mean force of 27 kilogrammes (73 pounds) was sufficient to produce a fracture; while in 32 subjects between eighteen and fifty years, a mean of 50 kilogrammes (135 pounds) was demanded, in some cases 100 kilogrammes (270 pounds) being hardly sufficient.

"Again, as to the ordinary seat of the fracture produced experimentally, I stated that the recollection of the results of my own experiments was not that there was any such uniformity of proximity to the articular edge of the line of fracture as had been found by Dr. Hamilton, but that in quite a notable proportion of cases—even, perhaps, an equal number of cases—was it a half-inch or more above. Of the specimens now presented, of the eight in which the fracture involves the whole breadth of the bone, three are fractured a half-inch or more above the articular edge. The whole series present a uniform lack of uniformity in the position of the line of fracture. On this point, also, I will quote the more extended experiments of Schmit (op. cit., p. 66), who says: 'We have found the seat of fracture to present the greatest variation, from within the articular facet, even as far up as four centimetres (one and one-half inch) above it; we have met all the numerous forms of the direction of the solution of continuity; all the different aspects which have been described by authors, and that without noting that any particular kind was most frequent at any special age.' The last proposition, that the line of fracture ordinarily produced in the living subject was a half-inch or more above the articular edge, is very much diminished in its force, by noting the very great variations in this respect which the specimens present that have been dissected and fully examined. The specimens in particular from the New York Hospital collection, which are before us, show great variations in the amount of the articular extremity which has been separated from the shaft.

"In one specimen (No. 125) the lower fragment is composed of the tip only of the styloid process of the radius; in a second (No. 127) the whole styloid process is broken off, the line of fracture running obliquely from its base downward to the bisecting ridge of the articular surface; in these two specimens, the dorsal lip of the articular surface of the radius has been crushed off, and a fracture of the scaphoid bone also sustained; in a third specimen (No. 122) a yet larger portion of the articular surface is included with the fragment, the line of fracture running from the base of the styloid process to the middle of the quadrilateral articular surface, for the semilunar bone; in a fourth (No. 121) the whole of the carpal articular surface of the radius is carried away with the lower fragment, by a line of fracture running very obliquely from the base of the styloid process to the point of junction of the ulnar and the semilunar articular surfaces.

"In other specimens, Nos. 120, 123, 124, 125', 129, of the New York Hospital collection, the lower fragment includes the whole of the inferior extremity of the bone, which is separated from the shaft by a line of fracture running nearly transversely, at points varying from one-fourth inch to one inch above the articular margin in front, with an antero-posterior obliquity, so that, on the dorsal aspect of the radius, the line of fracture is somewhat higher above the articular margin than was the case upon the palmar

aspect; in the specimen (124[a]), the line of fracture is lowest upon the dorsal aspect of the bone, where it runs along the epiphyseal line, about three-eighths of an inch above the articular edge; thence it runs obliquely upward as it approaches the palmar aspect, where it terminates about one inch above the articular edge.

"In the remaining specimen (No. 128), there is simply a longitudinal fracture running upward from the articular surface, near the ulnar margin, by which a bit of the radius containing the ulnar-articular facet is split off. This was accompanied by a fracture of the scaphoid bone.

"It is to be noted that all these were instances of injuries where a great degree of violence was sustained, and other injuries of fatal character received.

"Of three other specimens of recent fracture which I have examined, in one the styloid process and the scaphoid facet alone were torn off; in the second, the line of fracture was $\frac{1}{2}\frac{3}{4}$ inch; and in the third, $\frac{1}{4}\frac{4}{4}$ inch above the articular edge. It is evident from these how difficult and unsatisfactory must be the attempt to deduce any conclusion founded upon any arbitrary line along which the point of fracture is to run. Two general groups of facts, however, stand out as the result of the examination we have made. They are: first, experimentally every grade of fracture of the lower extremity of the radius, from simply the separation of the styloid process to a transverse fracture an inch and a half above its articular edge, has been produced by violent tension of the anterior radio-carpal ligament in forced backward flexion of the wrist-joint; second, every grade of this fracture, likewise, may result to the living person from a fall upon the palm of the hand. The question of interest, and upon which difference of opinion exists, is: What other force than that of tension of the anterior ligament is added in these falls, and what share does it have in producing the particular result? This force is that of impact. It is possible to analyze its application and its effects.

"The order of events which happen in falls upon the palm of the hand is as follows:

"First, the impact is sustained by the thenar and hypothenar eminences over the base of the metacarpal bones. In extreme extension the prominences of the trapezium and unciform bones become involved in the impact. That the fall should come upon the palm of the hand at all, it is necessary that the hand should be previously somewhat extended, in which movement the points where the impact is to be sustained are carried back of the axis of the radius.

"The immediate effect of the impact is to increase this extension. The distal row of the carpus glides backward upon the proximal row, the latter glides forward beneath the articular surface of the radius until it is checked by the distended anterior ligament, and the radius rests upon its posterior surface. The flexor tendons also—if the muscles be in contraction—antagonize this extension and reinforce the anterior ligaments. However, if the flexor muscles have been sufficiently strongly contracted to resist the further tendency to extension at the moment of the impact, the hand and carpus will be driven *en masse* upward, as the resultant of the forces of extension and flexion, and the convex surface of the upper row of the carpus will impinge against the broad, shallow, concave articular surface of the radius. In the transmission of the force to this point it will have already been greatly decomposed. The elastic adipose, fibrous and muscular cushions of the palm, and the two rows of carpal bones, cancellous in structure with their interposed cartilages, unite in repelling shock; whatever of strain has been put upon the flexor muscles is just so much force transmitted to the origin of the muscles and there expended; whatever of ligamentous strain is sustained is just so much of the original force transmitted to the insertions of the ligaments and there expended; whatever of the force of the original impact which is not thus expended is finally received upon the articular surface of the radius. Here an admirable arrangement is found to break up and render harmless whatever of force yet remains—a buffer of cartilage, upon which rests a cone of cancellous tissue which is grasped above by a cylinder of strong, thick, compact walls. All force transmitted to the lower extremity, other than that of very great intensity, of the radius, is here finally decomposed and repelled, or propagated upward along the shaft, to be modified by other and new conditions of muscular tension and articular relations, and intimate arrangement of bony particles, the result perhaps in fracture or dislocation above—the most common result in children, in whom, as is well known, fractures of the forearm by falls upon the palm of the hand are the most frequent of all the fractures sustained by them. If, however, by reason of the less degree of the resilience of the bone, as exists more and more with advancing age, and by the particular fixation of the whole extremity, the greater part of the force of the impact is expended upon the tissue of the lower extremity of the radius; and if, in addition, as the result of very great violence sustained, as in falls from a height, the impact of the carpus against the radius is more powerful than can be resisted by the mechanism which has been described, the result will be that the blunt wedge, formed by the carpus, driven against the concave articular surface of the radius, with a crushing force, will split it longitudinally. Many of the New York Hospital specimens illustrate the effect of this crushing force perfectly.

"In injuries resulting from comparatively slight violence—which includes the great mass of recognized fractures of the lower extremity of the radius—if this view of the effect of impact upon the lower extremity of the radius be correct, longitudinal fracture would not be present; but in falls from a height, in which the weight of the body with great momentum comes upon the outstretched palm, the conditions are presented in which, if our reasoning be correct, longitudinal fracture may be possible. These are the cases likewise in which other severe injuries are likely to be present, which, by their fatal results, may make actual inspection of the fractured bone possible. These are they which find their way to hospital wards and dead-houses. These formed the class of cases which Dupuytren inspected, and which gave rise to his graphic description of fragments shivered and splintered as if struck by a hammer. To this class belong the specimens now before the society. That the comminution of the lower fragments in these specimens is not the result of their penetration by the upper fragment—the explanation heretofore given of such comminution is apparent for the reason that not one of these specimens presents any indication of such penetration. The result of this analysis of the effects of impact I summarize therefore as follows:

"Impact of the carpus against the lower extremity of the radius is present to a greater or less degree in all falls upon the palm of the hand.

"Its effect is: first, concussion of the expanded ar-

ticular extremity; second, when more violent, propagation upward, with tendency to fractures and dislocation above, at points determined by special conditions met with in each case, this particularly in young subjects; third, crushing in, and longitudinal cleavage of the lower extremity of the radius, more marked with advancing age. The mechanical construction of the inferior extremity of the radius is such as to strengthen it against the effects of impact. The lines of the principal columns of its cancelli are arranged expressly so as to bear force applied in the line of the axis of the bone; the well-known experiment, in which a cubic inch of cancellous tissue with its principal layers upright being submitted to pressure, remained unchanged until more than four hundred pounds had been heaped upon it, illustrates its adaptability to sustain pressure applied in the long axis of the bone, notwithstanding its apparent fragility. It is like the patent car-coupling, the most important part of which is a wooden bar: while the train is running properly along its track, the longitudinal strength of this bar is sufficient to withstand the strain of any weight; but the moment a car leaves the track, and a cross-strain is brought to bear upon it, it snaps and disconnects the train. The lower extremity of the radius will bear any force applied to it in the line of the perpendicular columns of its cancelli, short of a crushing or clearing force, without injury; a cross-strain, however, takes it at a disadvantage—as has been proven by Schmit, a force of from seventy-three to one hundred and thirty-five pounds is sufficient to rend it.

"Impact, in this instance, is a force acting in the direction of the greatest strength of the bone. The injury in question is a lesion transverse to the long axis of the bone. In its production a cross-strain is necessary. What, then, is the source of this cross-strain? Is it of muscular origin? There is but one muscle that can exert a cross-strain on the inferior extremity of the radius—the pronator quadratus. To this, as Dr. Hamilton stated, did the first writer on this subject, Pouteau, of Lyons, in 1760, refer this fracture. This muscle is now so universally rejected as a cause, that it need not be discussed.

"Is it direct impact, as the great mass of surgeons to this day have taught? If the facts which have been passed in review in this note, and the conclusions based upon them are correct, impact must be rejected.

"Is it the same as that which determines the fractures of the lower extremity of the radius in experiments upon the cadaver, the tension of the anterior radio-carpal ligament in forced backward flexion of the wrist-joint? By a process of exclusion we are forced to accept this latter explanation. By a process of instruction it would be quite as certain to arrive at the same end. One question only has been under discussion, viz.: By what mechanism is transverse fracture of the radius within an inch of its lower articular edge produced? The many important complications, found in varying number in different examples of this injury, need not be discussed; but it will be found that the recognition of the primary agency of this force of avulsion will most satisfactorily explain their occurrence, when the total assemblage of the conditions which complicate each individual injury be considered, and likewise will be found to have an important bearing on the adaptation of remedial measures. While my final conclusion, therefore, is that the chief agent of this particular fracture is the anterior radio-carpal ligament, I do not for a moment mean to say that concussion, muscular action, the varying arrangement of the osseus trabeculæ of the cancelli, the varying cohesion of its particles, and perhaps other influences, do not have their effect in modifying the result. The particular injury in any given case is the resultant of all these forces and conditions."

Dr. E. L. Keyes mentioned a case in which the fracture was produced in a peculiar manner. A workman was caught in belting and carried over a shaft in a position of forced palmar flexion, the man being suspended by it, and the characteristic silver-fork fracture was produced. There was no lesion of the soft parts, and the fracture was reasonably high up. Evidently there was no impact, but there was leverage and avulsion.

Dr. Wm. T. Bull presented specimens of fracture at the lower end of the radius, produced by avulsion. Upon nineteen arms he had produced forced dorsal flexion, mostly by locking his fingers into those of the subject and forcing the palm of the hand back. The following was the result: in ten no fracture was produced, in five there was rupture of ligaments, and in five there was no lesion. In nine cases fracture was produced, and of those five were transverse, with the distance from about the centre of the articular surface three-eighths of an inch in three, one-half inch in one, and five-eighths of an inch in one. In the other four cases the fracture was oblique, and measuring as before, the oblique line crossed a point about one-half inch above the articulation. In all the experiments the amount of dorsal flexion was very much more than that which he believed existed when the fracture was produced by an ordinary fall.

One peculiar feature of his experiments was that in ten out of the nineteen cases no fracture was produced; and from his results—which of course were derived from too small a number of cases to be accepted as a general rule—Dr. Bull was disposed to recognize some other factor than simple avulsion in the production of the fracture under consideration.

Dr. L. A. Stimson added that, on leaving the building after the last meeting of the society, he stumbled, and falling, received a violent concussion upon the hand, sufficient to enable him to locate the point of impact. It was upon the heel of the thumb. Subsequently he went to the dead-house and sawed longitudinally through hands and arms, at a point corresponding to that at which he received the impact in his fall, and he found that it passed, not through the *third* metacarpal bone, but through the *second*, and through the scaphoid, the trapezium, and the trapezoid. He presented a tracing of the section, which showed, contrary to Dr. Pilcher's diagram, that the line of impact lay in front of the posterior border of the radius, and was directly continuous with the long axis of that bone, so that no crossed strain existed.

It was evident, from examining the specimens presented at the last meeting, that the hand is attached to the forearm in a manner which admits of considerable mobility—not in the angles of flexion and extension alone, but in direct elongation of the limb. When a man falls, all his muscles ordinarily are tense, and his hand is not at a right angle, but at an angle with the forearm of about forty-five degrees. Moreover, the tension of the muscles, both of the flexors and extensors, taking the place of the ligaments, draws the carpal bones strongly back against the radius, holds them there, and not only diminishes

the distance as represented in Dr. Pilcher's diagram, but brings the carpus still farther back under the radius.

It also seemed to Dr. Stimson that the flexor muscles received the first of that strain. In his own case there was none of the strain which one recognizes as received upon elastic muscles. The shock was transmitted directly through a bony line.

Dr. Hamilton remarked that—as he had already stated at the last meeting—the discussion rested mainly upon the existence of fact concerning what is observed in specimens; by which he meant to say that it was very difficult to settle this question simply with anatomical or physiological arguments. Dr. Pilcher has raised one point which is somewhat difficult to meet; and in effect it is that museum specimens—those presented from the New York Hospital and others—do not represent the classical fracture, but rather the injury produced by extreme violence, accompanied by other injuries which caused the case to terminate fatally. The same observation may be extended with equal propriety to all specimens, whether from museums or from private collections. Dr. Hamilton admitted that it was a difficulty with which the subject had to encounter. But we were not entirely sure that, if permitted to see all the cases which occur in private practice, and to make an examination of the bones, we should find the line of fracture different from that seen in museum specimens, in which the patient had died from the severity of the injury. The value of the argument, however, should be admitted. Yet there remains a sufficient number of facts to enable us to settle the question *presumptively* as to what is the causation, what are the efficient agents in the production of this fracture. If we should find, as he thought we had, that there was a greater uniformity than Dr. Pilcher seemed to think regarding the line of fracture in the museum specimens, that is, high up—in clinical observation it seems to be high up—and in those specimens which are furnished from the cadaver by avulsion, where there was presumptive evidence, may not the physiological argument show that I am more nearly correct than those who regard avulsion as the sole cause?

In addition to the ten specimens of fracture of the lower end of the radius, caused by avulsion upon the cadaver, and presented by me at the last meeting, I have now to present the following examples, supplied at my request by Dr. John H. Girdner, Asst. Demonstrator of Anatomy in the New York University.

1st. Female, aged fifty-six.—Right arm; forced dorsal flexion. Line of fracture curved from side to side, with convexity of upper fragment downward; nearest point one-half inch from the joint; also a fracture of the styloid process of the ulna.

2d. Left arm of the same person.—Dorsal flexion. Line of fracture oblique from side to side; nearest point one-half inch.

3d. Woman, aged fifty-six.—Right arm; dorsal flexion. Line of fracture irregularly transverse; nearest point one-half inch.

4th. Same person.—Left arm; dorsal flexion. Line of fracture nearly transverse; breaking off only the anterior lip of the radius, about one-fourth of an inch from the lower end.

5th. Male, aged twenty-five, strong muscular man.—Right arm; dorsal flexion. Dr. Girdner, applying the whole weight of his body—about one hundred and forty-seven pounds, was unable to break it. Another gentleman, weighing one hundred and sixty pounds, then added his weight, and the two united were unable to cause a fracture.

6th. Left arm of the same man.—Dorsal flexion. Their united strength would not break the bone; but something was felt to give way, which was probably some of the deep fibres of the anterior carpo-radial ligament.

7th. Right arm of an old woman.—Fracture at base of the apophysis of the radius.

Of the entire number—fifteen—which have been presented by me to the Surgical Society, illustrating fractures by avulsion made upon the cadaver, three were fractures caused by forced palmar flexion, and the remainder by dorsal flexion.

Of the examples caused by palmar flexion, none resembled in any respect the classical fracture.

Of the examples caused by dorsal flexion only three have any resemblance to the fracture in question, namely, the right and left arms of the woman aged twenty-two, and the right arm of the woman aged fifty-six, neither of which are removed more than half an inch from the joint.

Four of the examples of the adult males are fractures at the base of the styloid apophyses of the radius, and so also is one of the old women.

In only one example is the styloid process of the ulna broken off.

In not one of them is there such a comminution of the lower fragment, the only comminution being where the lower fragment is so thin as to break with its own weight, or where, as in one instance, there is in addition to the transverse fracture an entirely independent, oblique fracture extending into the joint.

In no case has there been some appreciable impaction or displacement backward at the point of fracture.

Certainly, to any one familiar with the study of this fracture, as it appears in the living subject from falls on the palm of the hand, most of these facts are inconsistent with the supposition that fractures caused by avulsion represent the classical fracture.

In short, it seems to me certain that to produce ordinarily the classical fracture there is required, first, impact; second, avulsion; and third, the action of the muscles to give stability to the bone, in order that the impact may act effectively and in the proper direction—that avulsion alone also is capable of producing a certain number of the fractures which result from a fall upon the hand, but not generally such fractures as have been hitherto recognized among English and American surgeons as Colles's fracture, and among other surgeons as the typical fracture of the lower end of the radius, caused by falls upon the palms of the hands.

In six more examples, not included in the above fifteen, two of which were adult males and four old women, it was found impossible, by avulsion, to cause a fracture, even where the hands were laid back upon the wrists—and in many of the other cases the fractures did not occur until the hands were nearly or quite in that position.

I wish to add, as a valuable contribution to this subject, the "Summary" of a series of experiments upon the cadaver and studies made by Dr. John H. Girdner, at my request, and which, with a detail of the experiments, may be found published in the Medical Record for Feb. 26, 1881.

*First.*—That, for the first few months of life, the epiphyseal junction is about three-fourths of an inch from the radio-carpal articulation, and that, if sufficient force be applied in a direction which in the adult would produce a Colles's fracture, there will be

a separation of this epiphysis, and the hand will present that deformity which is seen in Colles's fracture.

*Second.*—That, between the ages of nine months and one year the epiphyseal junction is within half an inch of the wrist-joint, and forced dorsal flexion will not produce a fracture of the radius, nor a separation of the epiphysis, but a bending of a bone about one-fourth of an inch above the epiphyseal junction, and the hand, left to itself, returns partly to its normal position, and the deformity is slight.

*Third.*—That, from the third to the seventh year of life (and perhaps to the tenth), the epiphysis of the lower end of the radius has almost completely changed to an apophysis, and forced dorsal flexion will neither bend nor break the radius, but will cause a stretching and partial rupture of the anterior ligament of the wrist-joint, and especially of Pilcher's ligament.

*Fourth.*—That, after the fifteenth year, and perhaps earlier, forced dorsal flexion will produce Colles's fracture with characteristic deformity. (The term Colles' fracture is used by Dr. G. as implying any fracture of the lower end of the radius.)

As has been suggested by Dr. Sands and by others, ordinarily, in a fall which produces this fracture, the hand is not placed at right angles; it is not placed in the condition of extreme flexion which is almost invariably required to produce it upon the cadaver. When a person falls in the street, he falls at length with the hand at less than 45° with the radius, so that the force of avulsion must be relatively inoperative.

Dr. Hamilton again directed attention to the striking frequency with which, by avulsion, the base of the styloid process of the radius is carried away just where the anterior ligament has its most powerful insertion. Certainly there was no prevailing expression of that sort found in the dead-house ordinarily.

### ANGIO-SARCOMA.

Dr. E. L. Keyes related the clinical history of a case, after which Dr. W. H. Welch described the pathological changes found in the tumor.

A man, twenty years of age, came to New York and consulted Dr. Sayre, who gave the opinion that the axillary tumor was a cancer, and advised its removal. Dr. Van Buren then saw the patient, confirmed the opinion given by Dr. Sayre, and also advised an operation, which Dr. Keyes performed in Bellevue Hospital on the 26th of February, assisted by Drs. Stimson and Yale, and in the presence of Dr. Sayre.

The tumor occupied completely the thoracic side of the axilla, extending under the pectoralis muscle. The patient was cachectic, and the tumor had grown with very great rapidity. At the time of the operation there was tenderness over the liver. The operation was exceedingly bloody—veins entering the growth from all directions—and the patient became very blanched, but rallied tolerably well. About two and one-half inches of the axillary vein were removed. No swelling of the limb followed. Secondary hemorrhage occurred on the tenth day—not profuse—and was arrested by pressure. The patient died on the thirteenth day. At the autopsy there were found three tumors in the liver; some local peritonitis over one of the largest metastatic tumors in the liver, which gave rise during life to a friction-sound; tumors under the mucous membrane of the intestines, under the peritoneum, in the muscle of the heart, in the lungs, in the spleen and in the kidneys, and in the mesenteric glands. The bones and the brain were not examined. There were no subcutaneous growths.

#### MICROSCOPICAL EXAMINATION.

Dr. Welch presented portions of the axillary tumor removed by Dr. Keyes, together with parts of the liver and of the lung, showing the metastatic growths in these situations. He also exhibited microscopical sections with drawings of the tumor from these various regions. The axillary tumor was of an irregular shape, about as large as an orange, and not enveloped in a capsule. In the fresh condition its cut surface had a variegated aspect, being in places black in color, in other places red, and in others white. The consistence was soft. A teased-out fragment of the fresh tumor showed chiefly large, epithelial-like cells. When hardened, the axillary tumor presented a peculiar and characteristic appearance. It consisted of a mass of closely compacted blood-vessels, varying from one-half to three millimetres in diameter. Each blood-vessel possessed a central lumen and a comparatively thick wall. The blood-vessels ran for the most part parallel to each other, and in transverse section the appearance resembled the cross-cut of a nerve-trunk, each blood-vessel representing a nerve-fibre, but possessing a lumen. In a few places the appearance was more homogeneous, the blood-vessels not being evident. It was possible, by teasing, to isolate the blood-vessels and thus to demonstrate the existence of branches, but no anastomoses were discovered.

By microscopical examination the axillary growth was found to present, in the most characteristic manner, the structure of an angio-sarcoma. In some places the blood was preserved in the lumen in the vessels, in others it was absent; in a few instances the vessel contained a thrombus. In the majority of blood-vessels two or three layers of smooth muscular tissue were present immediately surrounding the endothelial lining. Outside of the muscular ring was a narrow zone of a homogeneous, hyaline substance, and surrounding this was a mass of cells contained in the meshes of an adenoid reticulum. This cellular mass constituted the greater part of the vascular wall. The cells were in a few places scarcely larger than lymphoid cells, but for the most part were much larger, were irregular in shape, and resembled epithelial cells. In some places, especially in the periphery of the vascular wall, the cells were grouped together in large alveoli. The stroma between the vessels was imperfectly fibrillated, of a lax texture, and in places richly infiltrated with extravasated blood. Here and there it was of a mucoid character. It was especially in this intervascular stroma that cells containing yellowish brown pigment-granules and diffuse pigment were found, but similar cells also existed in the cells in the walls of the vessels. Exceptionally, the lumen of the vessels was obliterated by the new-growth. The structure of the metastatic growths resembled closely that of cancer, and for the most part was not to be distinguished from it. Occasionally blood-vessels presenting the same infiltration of their walls with cells, as in the axilla, were to be found, but in general the metastatic growths consisted of large alveoli filled with rapidly proliferating large cells like epithelial cells; the interalveolar stroma consists of vascularized connective tissue containing cells different in character from those in the alveoli. Cells containing granular and diffuse pigment were found mingled with unpigmented cells in the alveoli.

Dr. Welch said that a similar angio-sarcomatous growth of the axillary glands had been described by Putiata, and that Kolacgek, Maurer, and others, had observed the occasional presence of pigment-cells in these tumors, giving them a melanotic aspect. He remarked that the demonstration of smooth muscular tissue in the walls of the vessels was of interest, as it has generally been stated that the vessels in angio-sarcoma resemble capillaries, whereas in this case they resembled small veins. He was not able to determine whether the pigment in the cells was formed from the extravasated blood-globules or by a chemical metamorphosis of the protoplasm. It was, moreover, important to note that while the origin of the growth from the adventitial cells of the blood-vessels was clearly demonstrable, portions of the tumor presented a structure not to be distinguished from that of carcinoma, and that transitions could be observed between the adenoid reticulum containing lymphoid cells and the large aveoli filled with epithelial-like cells. Those who insist upon the epithelial origin of cancer would refuse to call these portions of the growth cancerous. This specimen, however, demonstrates, as others have done previously, that growths springing from connective-tissue cells may present all the morphological characters of carcinoma.

The society then adjourned.

## Correspondence.

### THE EFFECT ON THE EAR OF HIGH ATMOSPHERIC PRESSURE IN TUNNEL CONSTRUCTION.

To the Editor of The Medical Record.

Dear Sir: Now that a large number of men are employed in the construction of tunnels, any injury to which they are liable may be of interest to the profession. My attention was drawn to this subject shortly after work on the Hudson River tunnel was begun, by two of the workmen who applied to me for relief at the New York Eye and Ear Infirmary, on account of aural injuries arising from their confinement in the compressed air-chambers.

One of these patients, on examination, was found to have a subacute inflammation of the middle ear; he had contracted a cold in the head from exposure in the tunnel, and this had prevented the air passing freely through the Eustachian tube of one ear; air being thus kept out of the tympanum, the unusual pressure in the external meatus drove the drum-head inward, the consequences being pains in the ear, tinnitus aurium, vertigo, and deafness. The other patient was found to be suffering from the impaction of a collection of wax in the external meatus; he experienced pains in the ear from the increased pressure upon the impacted wax, and likewise had tinnitus aurium and vertigo. Although impaction might have occurred in this case under other circumstances, yet I am convinced that the drum-head suffered greater injury from the impaction of wax under the additional pressure than would otherwise have been the case.

The cause of aural troubles among workmen and others who may frequent these compressed air-chambers is quite evident: the usual air-supply is cut off from the tympanum, either by closure of the Eustachian tubes from cold in the head, or perhaps by the direct pressure on the guttural mouth of the tube; the extraordinary pressure on the drum-head from without, of three or four times the ordinary atmosphere, in the meantime forces the drum-head inward, causing great tension of the transmitting mechanism and inflammation of the middle ear. As is well known, in the normal condition of the ear there is a constant renewal of air in the tympanic cavity during each respiratory act, thus enabling the membrana tympani to perform its functions; when, however, the tympanum is deprived of its normal air-supply, there is no longer any resistance to the external pressure, and retraction of the membrane is unavoidable.

The injurious effects of the compressed and unwholesome air of tunnels on the health of workmen are well known. Dr. John Green, who made some interesting observations on the subject during the construction of the piers of the Mississippi River bridge at St. Louis, some ten years ago, states that rupture of the tympanic membrane sometimes occurred to those who exposed themselves in the air-chamber.

I am inclined to believe that no one can remain long in an atmosphere of some sixty pounds pressure to the square inch without experiencing unpleasant effects in the ear, and the greater number of those who have chronic aural diseases would soon be more or less incapacitated. Should catarrhal troubles be experienced—and as a matter of fact they are very common among these underground laborers—closure of the Eustachian tubes would most likely occur.

We may, therefore, conclude that injury to the ears can only be avoided, in even healthy individuals, by the observance of certain precautions, and that a large number of those employed in tunnel construction cannot escape, however careful they may be.

It would seem to the writer that there should be a medical examination of the ears of all laborers before they are permitted to enter an air-chamber where the pressure is over two atmospheres, and that, where men are exposed to a greater pressure, the possible effect on their ears should not be overlooked.

In order to prevent injury to the ears during the period of exposure, the writer would suggest that respiration should take place with the mouth closed; that whenever a feeling of increasing pressure is experienced, further relief may be obtained by resorting to the Valsalvian experiment or to the act of swallowing. These recommendations may seem unimportant, but one may well believe that men in the condition of the patients I have alluded to above would be incapacitated for any position where the lives of others might depend on their clear-headedness and good hearing. The men themselves often have reasons for concealing defects even when pain or deafness exists; hence the necessity for frequent examinations being made.

Samuel Sexton.

12 West Thirty-fifth Street, June 30, 1881.

Spain versus the Buchananites.—Spain has risen up against the Buchananites. A recent royal mandate prohibits the practice of medicine and surgery on the part of those who hold bogus diplomas issued by the notorious Dr. Buchanan. Cuba particularly seems to suffer from the presence of this class of practitioners.

## CURARE AND MOTOR-NERVE ENDINGS.

### A Response to Dr. Reichert.

To the Editor of The Medical Record.

Sir: I regret that a recent criticism of Dr. Reichert on a previous article of mine on the above subject is, to some extent, founded on an entire misapprehension of the tenor of my thesis; that other portions of his criticism are disingenuous and unfair, and place words, ideas, and even propositions in my mouth for which I am not only not responsible, but which I repudiate. Any one at all conversant with the scope of previous articles of mine in the Record, must be aware of this almost at a glance. I am charged with a misquotation, which I flatly deny. Several of the arguments put forward by Dr. Reichert as comparatively new—for example, those relating to the sartorius, to ideo-muscular contraction, to the behavior of protoplasm, etc.—have been superseded by still more recent facts, and the subject was discussed by me at some length in the Record of March 26, 1881, and elsewhere. As no attempt has been made to refute these arguments, and as I am of opinion that a discussion on the subject between Dr. Reichert and myself would be neither to our mutual advantage nor to that of your readers, I must decline any further reply. I am quite content to leave the matter, as it stands, to the judgment of the profession, and, if need be, to that of posterity. Yours, etc.,

Thomas W. Poole, M.D.

## GUNSHOT-WOUND OF LIVER.

To the Editor of The Medical Record.

Sir—In view of the great interest manifested just now in gunshot-wounds of the liver, both as to prognosis and treatment, I make bold to send you a few notes of a case which occurred last winter at this post, and hope they may not be without interest to the profession and encouragement to the numerous friends and admirers of President Garfield.

Robert Nelson, colored, a private of Company A, Ninth United States Cavalry, born in Richmond, Va., aged twenty-seven, was wounded on December 2, 1880, at the Mescalero Indian Agency. The patient was on horseback, and was shot by an Indian on the hill above him. The projectile, presumably a conical rifle-ball (calibre $\frac{44}{100}$ of an inch), shot from a Winchester repeating rifle, entered the body over the sixth left costo-sternal articulation, passed thence from left to right in front of the junction of the xiphoid cartilage and the gladiolus, from thence somewhat backward and downward, emerging just below the eighth rib, about two inches anterior to its angle. The shooting occurred thirty-eight miles from the post. At first it was not supposed that the chest-cavity had been entered, but from the superficial course taken by the ball at the wound of entry it was surmised that its entire track lay between the ribs and the skin, as quite often happens. On December 4, 1880, about forty hours after the infliction of the wound, the patient was put into an ordinary government spring-wagon and brought in a continuous journey into the post. He bore the ride remarkably well, only complaining when severely jolted. He was made as comfortable as possible. Did not suffer markedly from shock. There was no considerable hemorrhage; no great pain; mind clear and hopeful. The next morning, Acting Assistant Surgeon Atkins, U.S.A., passed a probe from the wound of entrance through to that of exit. The probe (a long one) passed in a nearly straight line, and demonstrated beyond a doubt that the bullet had cut its way through the lower anterior portion of the right lobe of the liver. The periosteum had been scraped off from the anterior surface of the sternum and from some portions of the ribs. No bones had been broken, and the gall-bladder was not, to all appearances, wounded (however, more of this anon).

The patient is a remarkably strong, tough negro, nearly black. Says that he has never been sick, except once with a broken leg, from which accident he made an excellent recovery.

No other surgical treatment was adopted than daily washings with carbolized water. (The water for several days could be injected entirely through the wound.) Tonics and nourishing food comprised the rest of the treatment. Only on December 8th and 9th (the sixth and seventh days since the infliction of the wound) did the temperature show a considerable rise, and was easily reduced by quinine. After one good purge had been administered the bowels acted normally, and the appetite had rather to be checked than encouraged.

The patient, like our distinguished President, is of a brave and cheerful disposition. Indeed, he was wounded in the discharge of an arduous duty, which he voluntarily undertook.

In a few days after admission to the hospital the discharge from the lower wound, which had been at first quite moderate and sero-sanguinolent in character, began to increase in quantity and become quite yellow in color. The upper wound (that of entry) soon closed. In ten to twelve days a considerable amount of nearly pure bile was found every morning upon the bandages. This discharge proved quite acrid, and considerable patches of skin on the abdomen, side, and back were lifted off by it. The patient had never complained much of pain, but when the biliary matter ran over the excoriated surfaces he would cry out bitterly. For a while the patient complained of a cough which hurt his side and aggravated the discharge.

For about three weeks this abundant discharge continued, seeming more like pure bile every day, then suddenly almost ceased. Again, in about forty-eight hours, it returned, and was more abundant than before. Fears were now entertained that a permanent biliary fistula would establish itself; but our apprehensions proved to be unfounded, for the wound went on to heal kindly. The injections of carbolized water were discontinued, and on January 25, 1881, less than eight weeks since he was shot, the patient returned to duty with his company.

For a while he was put on light duty and not required to wear a belt, which distressed him, but at the present writing he is doing full military duty, and has done so for a considerable time.

He informed me to-day (July 14, 1881) that he is as well as he was before he was wounded, except that he is not quite so strong generally, and cannot lift such heavy weights as formerly. He also, at times, notices a slight stitch in his side upon coughing or sudden and severe exertion, but attaches no importance to it. Very respectfully yours,

Richard C. Newton, *Asst. Surg. U.S.A.*

Fort Stanton, New Mexico, July 14, 1881.

The American Otological and Ophthalmological Societies held their annual meetings at Newport, R. I., during the past week.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 17, 1881, to July 23, 1881.*

AINSWORTH, F. C., Capt. and Asst. Surgeon. Relieved from duty at Fort Clark, and assigned to duty as post surgeon at Fort McIntosh, Texas, relieving Asst. Surgeon Gorgas. S. O. 90, Department of Arizona, July 14, 1881.

GORGAS, W. C., 1st Lieut. and Asst. Surgeon. When relieved at Fort McIntosh, Texas, to report to commanding officer Fort Duncan, Texas, as post surgeon. S. O. 90, C. S., Department of Texas.

## Medical Items and News.

THE PRESIDENT'S WOUND.—Dr. W. H. Dukeman, of Olean, New York, writes: "The article on 'The Wounded President,' of July 9th, was read with the deepest interest, and has furnished the public with the most accurate and intelligible account yet published. But it does not seem possible, much less probable, that the ball is lodged in the liver. Had the ball struck the eleventh rib and glanced upward and struck the tenth, the direction of the spent ball would be in a downward direction, owing to the position of the rib. Again, if the ball first struck the tenth rib and glanced downward as to strike the eleventh, from the position and slant of the eleventh rib in the posterior region of the body the ball would again take a downward course. From the anatomical outlines and borders of the ribs, it seems very clear to me that the course of the ball was in a downward direction, and from the great amount of tissues in so muscular a man, there would be so much spent force that the ball could not reach the substance of the liver, respiration greatly interfering with the force of the ball by the change in the position of the various tissues intervening, and the great amount of elasticity thereby produced. With these and various other obstacles of minor importance, I am led to the conclusion that the ball has taken a downward course and is lodged in the intervening space existing between the membranes of the internal organs and the posterior abdominal muscles. The experiments performed by Professor Weisse are of little value, for in the cadaver everything is at perfect rest, while in the living subject, as already shown, motion would greatly interfere with the direction of the ball.

"I would suggest that the Professor make the experiment on the assassin, provided he is a skilled marksman."

GUNSHOT-WOUND OF ABDOMEN.—Dr. James C. Neal, of Archer, Fla., writes: "The interest taken by the profession in the recent tragedy at Washington will doubtless call up many similar cases, and having had a remarkable instance in my practice I present it:

"In January, 1878, Ed. P——, a muscular negro, twenty-six years of age, while card-playing with a white man, in a saloon at this place, was shot with a heavy Colt's navy revolver, at less than five feet distance, the ball entering the abdomen one inch below and two inches to the left of the umbilicus, emerging an inch above the crest of the right ilium and about three inches from the centre of the spinal column, then through an inch of yellow pine plank, five feet behind the negro. I saw him twenty minutes afterward; found him cold, nearly pulseless, and vomiting at first blood mixed with the half-digested food in the stomach, then fresh blood alone. There was considerable hemorrhage from both wounds—the anterior showing a bloody knuckle of intestine, the posterior a lacerated fragment of omentum. I gave him a tablespoonful of brandy in which a drop of dilute acid. carbolic. had been dissolved, restored the intestine and omentum to the abdominal cavity, stitched up the wounds, applied water-dressings, gave him a quarter-grain of morphia, and exhorted him to prepare for a speedy exit. That night he again vomited blood, and passed a quantity of clot and some fresh blood per anum. The next day he was removed home—two miles. Some reaction set up the third day. I gave morphia freely, enjoined abstinence from solid food, used cold-water compresses, and, to everybody's surprise, the eighth day afterward he walked into town and began work.

"While replacing the intestine I could easily introduce my thumb, and at so close a distance the heavy ball did not dodge anything. I have often wondered if the ball was not heated enough to partially burn the penetrated tissues.

"The patient is a burly rail-splitter, lives on fat bacon and corn-bread, is unclean in habit, and much given to whiskey. He lives near here, and, D. V., I hope to make a P.-M. of him some day, to ascertain what injuries were sustained, as this will be about all the satisfaction I will ever get from the case."

THE NEW YORK MEDICAL MISSION is a somewhat novel form of charity, which has just been established in this city, at No. 5 East Broadway. From 9.30 to 10 A.M., the names of persons who wish medical treatment, but are too ill to leave their homes, are taken. At 2 P.M., a short religious service is held, after which the patients will be treated in the dispensary. The medical superintendent is Dr. George D. Dowhout, who has been very successful in establishing similar missions in London and Philadelphia.

SEA-AIR AND INFANTILE DIARRHŒA.—The Sea-Shore Home has just issued its annual report for 1880. Dr. Edward T. Williams, the physician in charge of the home for several years, thus sums up his experience:

"1. Sea-air is *not* an infallible cure for infantile diarrhœa. Some cases will die under the best management.

"2. The vast majority of cases get well, if removed early and properly fed and cared for.

"3. After decided collapse and head-symptoms come on, death is the rule, recovery the fortunate exception.

"4. Bronchial and pulmonary complications are usually aggravated by the cold air.

"5. Not a few cases are made worse by exposure in stormy weather, and the cold nights of the last of August and September; at these times, both fires and extra clothing are needed, and some take cold in spite of them. Indeed, it has seemed to me that the autumnal diarrhœas are chiefly caused by cold, and are unsuited for the sea-side."

ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.—The forty-ninth annual meeting of this association will be held at Ryde, Isle of Wight, on August 9, 10, 11, and 12, 1881, with Prof. G. M. Humphrey, President, in the chair.

The address in medicine will be delivered by Dr. John Syer Bristowe.

The address in surgery, by Jonathan Hutchinson.

The address in obstetrics, by Dr. John G. Sinclair Coghill.

The work of the meeting will be done in four sections and one subsection.

Fifteen subjects have been arranged for discussion. In medicine, Dr. Gowers will open a discussion on acute spinal paralysis, and Dr. L. Brunton a discussion on jaundice. In surgery, Mr. Stokes will open a discussion on resection of the knee.

Battey's operation, and the mechanical treatment of uterine flexions and displacements will be discussed in the obstetric section.

In the section of public medicine, the subject of vaccination with calf-lymph, the origin of enteric fever, and cremation, will be discussed.

There will be the usual annual exhibition of instruments, drugs, specimens, and books.

THE SOUND PRODUCED BY CONTRACTION OF THE TENSOR TYMPANI.—Dr. G. H. Felton, of Lynn, Mass., writes: "This sound, referred to by Dr. Cruse in a recent number of the RECORD, and by others previously, is one that I have always been able to produce at will, without contracting any facial muscle. I have the same control over the tensor tympani, to the contraction of which I also attribute it, as over any other muscle, except that I cannot cause its contraction in one ear without causing it in the other. This rhythmic character of muscular contraction, here apparent to the ear, may also be demonstrated by very powerfully contracting the flexors of the forearm, for instance, which causes a trembling of the arm, both seen and felt."

ELECTRO-MASSAGE.—Dr. J. Butler writes: "There are two articles in your issue of June 25th to which I am impelled to call your attention in the name of justice and fair play, the first on 'Electrolytic Urethrotomy,' on page 709, and the second, 'Instruments for Electro-Massage,' page 724.

"In regard to the first-mentioned article ('Electrolytic Urethrotomy'), I would say that in the spring of 1879 I wrote an article describing this operation in detail, and giving the result of several years' experience with it; giving also a description of the instrument which I had invented and used for performing the operation. This article was published in the *American Journal of Electrology and Neurology* for October, 1879, a copy of which I now send you. The method I adopted and recommended was precisely similar to that now described and claimed as original in your columns, as you will see by referring to the journal sent.

"In reference to the second article, permit me to say that in the *Medico-Chirurgical Quarterly* for January last, there appeared from my pen a description of a new treatment, to which I gave the name of 'electro-massage,' the name, the treatment and the instrument for carrying out the treatment being original. Since then, the substance of this article has been copied into a large number of medical journals. The leading physicians all over this country use the treatment, recommend it, and acknowledge its source. Previous to writing this article I had employed the treatment for years, tested its value, and made the instrument as perfect as possible before putting it before the profession. I mention these points to show that the treatment has been in use a considerable time, and also that it has been made thoroughly public. Imagine my surprise, therefore, on opening the pages of your journal, on finding an article on 'Instruments for Electro-Massage:' an article describing Duchenne's old roller, and claiming it as original; the old and well-known electric brush, and claiming it as original; and, lastly, *my* electro-massage—or, rather, an inferior imitation of it—is counterfeited and claimed as original, and not one word of credit given to the original source.

"In conclusion, I would remark that the article in question is peculiarly well written for a nurse. It is certainly rather unusual to hear a nurse talk about cords, arcs, degrees, tangents, radii, etc."

MENTAL DISTURBANCE IN CHOREA.—Dr. E. C. Spitzka writes: "In your issue of July 9th, a report of the proceedings of the New York Neurological Society represents me as denying the existence of mental disturbance in chorea. Without the qualifications which I added to that statement, I should be seriously misrepresented by such a report. What I did say was, that excluding a series of cases not exceeding ten per cent. of the total, and aside from the irritability naturally due to an annoying affection, that there was no mental disturbance in chorea of children. The contrary position taken by several members of the society was that mental disturbance was a constant feature, and one member stated that even where no other defect could be discovered, at least a decided moral obliquity would be found.

"I refrain from adding to what was stated at the meeting, as I trust to deal with this question *in extenso* soon. But I would ask for the insertion of this correction, in order that those whose large experience with cases of mild chorea enables them to come to a reliable conclusion on this head, may not suppose an extreme view to have been promulgated, which was in reality never entertained."

SMALL-POX AND THE EFFICACY OF VACCINATION.—This question has recently had new facts brought to bear upon it by Dr. Buchanan. During the past year the death-rate per million in London, from small-pox, was ninety among the vaccinated against three thousand three hundred and fifty among the unvaccinated. Similar statistics show that the mortality among children under five years of age was forty and one-half per million among the vaccinated, against five thousand nine hundred and fifty among the unvaccinated. Among adults the mortality rates are one hundred and eleven for vaccinated, to one thousand nine hundred and six for unvaccinated. These figures show very clearly the efficiency of vaccination, and also the need of revaccination.

GYNOMANIA ONCE MORE.—A subscriber sends us the following: "My attention has been called to Dr. H.'s description of a gynomaniac, as he has named him, and Dr. Spitzka's remarks on the same in your valuable journal. The latter remarks that they are very rarely committed to the lunatic asylum; but, I would add, they are more often sent to jail. In the summer of 1876 one of your city judges actually sentenced such a person to *six months* on the Island, in default of bonds for a *thousand dollars*. If this is recognized by the faculty as a disease, and is, as Dr. Spitzka remarks, incurable, should it be punished as a crime, especially when the practice of these little peculiarities injure no one but the poor maniac?

"I think it would be well to request some one of these peculiarly constituted men, who have such an irresistible passion for lady's attire, to exhibit himself to the faculty, or at least permit a committee of eminent men to examine him physiologically and psychologically, so as to ascertain, if possible, the laws that govern such phenomena."

## IMPORTANCE OF THE EARLY RECOGNITION OF EPILEPSY.

AN ESSAY READ BEFORE THE CONNECTICUT STATE MEDICAL SOCIETY, MAY 26, 1881.

BY E. C. SEGUIN, M.D.,

NEW YORK.

THE paper which I have the honor to submit to the society is one which treats of an eminently practical subject, handled, I trust, in a practical manner. It is upon the importance of the early diagnosis of epilepsy in its principal forms. This essay is also a logical correlative of the one which I presented to the Medical Society of the State of New York in February of this year, upon the early diagnosis of some organic diseases of the nervous system.*

My attention has for several years been attracted by the fact that most cases of epilepsy were allowed to go on for months or years, perhaps passing the stage of curability, without a correct diagnosis and proper treatment. The mistakes of this sort which come under the observation of specialists are very numerous, and many of them have been committed by leading members of our profession. I shall present a number of histories of cases illustrating these errors of diagnosis, and I would earnestly request my readers to bear in mind that I cite these mistakes only for the purpose of instruction, and not at all with the idea of fault-finding or of exalting my own diagnostic acumen. Several of the physicians referred to anonymously in the following pages are gentlemen who are really eminent as teachers and practitioners, and at whose feet I would be glad to sit. Their errors were not due to carelessness or ignorance, but to a too ready acceptance of medical laws which pass current, yet are wrong.

The subject in hand is really a very complicated one, and I cannot pretend, in a paper whose length is limited, to enter into full details concerning the diagnosis of all the forms of epilepsy, and of the various symptom-groups which may be mistaken for it. To do this would involve a prolonged and minute discussion of many mooted points.

All I can do is to show that in most cases even the first attacks of epilepsy, of grand-mal and of petit-mal, can be recognized as epileptic.

I shall first relate cases in which the grand-mal or regular spasmodic attacks were allowed to go on without proper treatment for want of a correct diagnosis, and offer some comments on each case.

CASE I.—Female child, aged eleven years, seen May, 1881. Was always a bad sleeper, of a restless disposition, and irritable. Was easily made to turn pale under excitement. Nights disturbed by talking, crying, and even by nightmare. Five years ago the family physician regulated child's diet and instituted some simple treatment; since which attacks of pavor have been infrequent—very rare during the past winter. Never had chorea. Indigestion has been a prominent feature in the child's life; she was fond of sweets. The urine was often found laden with oxalate of lime, and once, last summer, a trace of albumen was discovered.

As regards any tendency to epilepsy, it appears that the child's mother is very nervous, and that one of her brothers was epileptic from childhood, in consequence of a fall (?).

In June of last year the patient travelled about somewhat, alone with her father, without the supervision of mother or nurse. Was probably a great deal exposed to the sun. On or about June 20th, in the early evening, while out on the grass, fell in a severe convulsion. Seemed in poor health afterward, and the family physician, considering the attack as caused by indigestion, or at any rate as symptomatic, prescribed a strict diet and an occasional dose of calomel.

On September 29th, in the cars, returning home from the country, was excited and overheated. After arriving at the house had her second attack, characterized by loss of consciousness, universal spasm, frothing at the mouth. Did not bite tongue, and was not inclined to sleep after fit. Traces of albumen in urine. Treatment was still directed to the disordered state of the digestive apparatus as a cause of the epileptiform attacks.

A week later, October 6th, after some excitement, in presence of her mother, suddenly fell in a convulsion, lighter than the previous ones.

After this a moderate bromide treatment was added to the management of the case, and no attack occurred until April 25, 1881.

The bromides, though given judiciously and by a very skilful hand, produced irritability and other disagreeable symptoms, which led the child's mother to cease giving them some time in January.

An attack on April 25th was characteristic, but slight, and followed by sleep. After it urine found laden with oxalate of lime.

May 2d, while the child was being prepared for bed, she felt some warning sensation (not a definite one); rushed, nearly undressed, to her mother, stood speechless before her, and was slightly convulsed in the throat.

A sixth and last attack occurred in the evening of May 8th. Sat in a spasm, foamed at the mouth; was rigid one instant, and then had clonic spasms of extremities; face not convulsed (?); pupils not observed.

There have been no "dizzy spells" or petit-mal.

It is needless to add that I advised a resumption of the bromide treatment in this typical case of epilepsy, with special precautions against severe bromic symptoms.

This case is peculiarly instructive, because the physician who treated it as one of lithæmia and oxaluria, with symptomatic convulsions, is an unusually intelligent practitioner and a gentleman of high standing in the profession. His judgment was warped by the currently accepted notions of the frequency of eclampsia.

CASE II.—Mrs. C. S., aged thirty-four years, seen March, 1879. Former health good. During 1876–77 she had had much malarial fever, irregular chills, and attacks of fever.

In April, 1878, after having been confined to the house by an attack of fever, she had a first convulsion. This occurred in sleep, after dinner, at about two o'clock P.M. It was a full convulsive seizure, in which she bit her tongue, fell heavily from the lounge on which she was lying, and hurt her face.

A second attack recurred on the night of August 2d. She groaned, was convulsed, frothed at the mouth, and bit her tongue.

A third attack of grand-mal occurred in the night of January 1–2, 1879. This was less severe, but she bit her tongue.

* *Vide* THE MEDICAL RECORD, February 26, 1881.

Has had few attacks of petit-mal, consisting in momentary confusion.

The significance of the first attack was ignored in this case, and a bromide treatment was not begun until after the second seizure. Since then has had bromide irregularly, at times too little, sometimes none at all, and occasionally too much.

Etiology obscure. Owing to patient's age and the absence of any inherited tendency, I inquired particularly as to symptoms of syphilis, with negative result. Frequent examinations of the urine have shown no sign of renal disease. As regards syphilis, the subsequent course of events, improvement without mercury or iodide of potassium, has justified my conclusion at the time of my examination.

It is sufficient to state, with respect to treatment, that Mrs. S. was put on a careful course of chloral and potassium bromide, which last year was changed to ammonium and potassium bromides. She has never required very much of the anti-epileptic medicines, and at times has had various tonics.

To the present time, May, 1881, a period of twenty-nine months, she has had no attack of either kind, and her general health is excellent. Since the beginning of the year I have made a small reduction in the amount of bromide, and intend to make a further reduction of a few grains every three months. Her present dose of the mixture of ammonium and potassium bromides is .50 (7.5 grains) on rising, and 2.5 (37.5 grains) at bedtime.

If, after exclusion of uræmia and syphilis, the first attack had been diagnosticated as epileptic and treatment instituted, the probability of cure would have been greatly enhanced. The next case is an illustration of this statement.

CASE III.—Miss F. O., aged sixteen years, seen May, 1878. A well-developed, healthy girl, menstruating since three years, with little pain. Mother neurasthenic; one brother had an exquisite attack of articular neuromimesis (both ankles). Patient never hysterical.

Yesterday, May —, menses were flowing, when, in order to be able to go with comfort to a dancing-school *soirée*, she used a cold foot-bath and checked the flow. She danced a good deal in the course of the evening, and then took supper. To-day arose late, and seemed languid. At about seven P.M. had a severe fit; gave a cry, lost consciousness, fell heavily; body was rigid and pupils wide open, then had clonic spasm, frothed at the mouth, and bit her tongue; was stupid and sleepy after attack, whose actual duration was not timed. It was witnessed by a very intelligent young gentleman, who gave me the above particulars. I saw the patient at eight o'clock —one hour after the fit. She was conscious, complained of headache, of soreness in body generally, and of her bitten tongue. The pulse was rapid, the axillary temperature was over 37.8° C. (100° F.); the patient's face and neck were covered with numerous minute petechiæ resembling flea-bites; menses had returned.

The seizure was typically epileptic. I anticipated a return of attacks only at the menstrual periods, and consequently instituted a rather peculiar treatment, which was carried out with unusual faithfulness. Bromide of potassium, 1.50 (about gr. xx.), was to be taken night and morning for ten days, including the menstrual period; beginning three or four days before it; and the patient was to be kept in bed or on the lounge for two or three days at the beginning of the flow.

A few days ago (May 14, 1881) I had a note from the patient's mother, stating that her daughter had never had a return of spasm (or any other epileptic manifestation), and that she was still keeping quiet for two days in the menstrual week, and taking bromide of potassium.

This makes an interval of more than three years, and I must say that I consider a return of attacks exceedingly unlikely. Still I have recommended continuing the periodical treatment for six or eight months longer.

CASE IV.—Mr. C. D——, aged twenty-one, seen February, 1877. Patient is a large and well-developed young man, something of an athlete. Former health good, but hygiene bad; used wine and tobacco from twelve to eighteen years, and probably committed sexual excesses. No epilepsy in family; mother subject to migraine; patient not. No dizzy spells. Head not injured.

First attack occurred when he seemed in good health, on Christmas day, 1873. Was sliding down hill, when he lost consciousness and fell off the sled, remained stiff for a few minutes, and was sick at his stomach. From his knowledge of the circumstances and from what he was told, the patient is positive that the fall from the sled was not accidental, but that he first "fainted." In two or three days was well.

Remained perfectly well for ten months, and had a second attack in October, 1874. Was sitting chatting with friends; lost consciousness, became sick at the stomach; did not bite his tongue. Had muscular soreness the next day. In the summer of 1875, after rowing on Lake George, had a third attack, without aura; fell off a dock into the water. Fourth attack in May, 1876, preceded by an undefinable preliminary sensation; attack was again accompanied or followed by vomiting. Fifth attack in October, 1876. This was treated, by Dr. X., as stated in the letter which is appended. Another attack occurred toward the close of 1876, and the seventh (last) seizure was on February 9th of the present year (1877), without warning or vomiting. In the other attacks the warning sensation was quite prolonged; on one occasion was able to walk nearly a quarter of a mile before falling.

He has had no petit-mal, and general health has been unimpaired. Has done well at college.

The following letter was sent to me with the patient, and it well illustrates the erroneous notions which prevail with respect to the significance of a single epileptic fit, or of fits returning at long intervals.

NEW YORK, February 11, 1877.

"————:

". . . . This will be handed you by Mr. D——, who has been under my care for some time with epilepsy. At first I attributed his attacks to gastro-intestinal causes, and rectified all bad habits of life and regimen. The disease recurred, and then I put him upon a diet exclusively vegetable and interdicted stimulants. He will tell you how he has fared upon this plan. . . ."

It appears that Mr. D—— was first prescribed for by Dr. X., who is a very eminent practitioner and teacher in New York, after the fourth or fifth attack, in 1876, when the disease had been going on two years and more. No bromide of potassium or sodium had been given until within a very short time previous to the consultation.

Though foreign to my present purpose, I might add that a bromide treatment, consisting in giving only a night dose of from 4. to 5. (60 to 70 grains) of bromide of potassium, has greatly improved the patient.

After the consultation some attacks returned, and I find the following record, July 16, 1878: Mr. D—— returned from Germany a few days ago. He had had no attack since the beginning of August, 1877. Once in Europe had a slight threat of attack, without loss of consciousness. Has led a regular, quiet life, and has taken 4. (60 grains) of potassium bromide every night without omission. General health excellent.

August 4, 1869.—No attack since threat in Germany, twenty months ago. Takes 4. (60 grains) nocte; ordered reduce to 3.5 (50 grains).

October 19th.—Slight attack after an interval of twenty-eight months; fell and bit his tongue. Ordered 4. at bedtime.

December 6th.—No attack.

September, 1880.—In August, under excitement, fell faint, but this attack was not sudden, and he preserved his consciousness. It is now nearly one year since last attack. Takes only 2.75 (41 grains) bromide of potassium at night. He reduced without advice.

October 14th.—Slowly developed attack, without local aura; felt confused before losing consciousness; had spasm, but did not bite tongue. Ordered 4. (60 grains).

January 5, 1881.—No attack. Through erroneous weighing of bromide, has taken only 3. (45 grains) every night. Ordered 4. (60 grains).

March 23d.—No attack.

*Summary.*—Since August, 1877, only two epileptic attacks, and one "threat." This is a period of now (June, 1881) nearly four years.

Has finished the study of law, and is in good physical and mental health.

Case V.—Ira K., aged eight years, seen February, 1877. Was a healthy baby; no convulsions while teething. When two years old fell down a long flight of stairs without apparent injury. Remained well. When four years of age, fell from a horse, cutting the scalp in the occipital region; no loss of consciousness or vomiting.

In six or seven months after this injury, about three and a half years ago, had a first (?) nocturnal epileptic attack. Until lately has had chiefly nocturnal spasms. At first had a few diurnal seizures, and again lately.

Has had much petit-mal, increasing in frequency—of late almost daily. This consists in staring, loss of consciousness, a "hum" or "hem" noise, and sometimes slight jerking of the arms and throwing back of body.

In the last few weeks child has been less bright, and has exhibited a thick articulation.

During long periods of time the child was treated "for worms" and for "disorder of the stomach."

Case VI.—Mary C——, aged sixteen years, seen October, 1879. Born healthy and remained well until sixth year, when, after indulgence in green fruit, she had an attack of very severe convulsions lasting two hours; did not bite her tongue, and there was no consequent paralysis.

This was succeeded by numerous "fainting turns," as the mother calls them. In these the child was unconscious, pale, still, with eyes open and staring. This was petit-mal; the next attack of grand-mal occurred in two years, and afterward the convulsive seizures became frequent, from one or two in one day to one in two or three weeks.

The child had an irregular bromide treatment.

Since has had three types of attack: petit-mal (rarely now), grand-mal, and mixed attacks. One of the last kind was witnessed in my office, and is thus described in the case-book: "Makes complaint of aura, asks for amyl, dilatation of the pupils, pale face, general spasm of semi-tonic kind, muttering, raising of clothes, picking or grasping at chair, incoherent remarks, makes some swallowing movements, does not bite tongue, or froth; return to consciousness."

The aura referred to is almost always felt; it consists in a sensation just above the umbilicus, not ascending, but feeling as of a "soft whirling" or "trembling" sensation in the abdomen; no nausea.

I mention this case because of the apparent etiology. It may have been looked upon as a case of convulsion and vertigo from gastric irritations, and treated accordingly. It certainly appears that a serious bromide treatment was not given during the first two or three years of the disease.

Case VII.—Clara C——, aged five years, seen April, 1880. In February 1879, had a first attack of convulsions, on both sides of the body.

In four weeks experienced a second bilateral attack. In April there recurred an attack in which the spasm was wholly limited to the left side of the body, followed by a number of others, all within a period of twelve hours; no consequent paralysis. In the month of May passed through another *status epilepticus*, in which some of the spasms were on the left side, others bilateral. The bromide of potassium was then steadily given until June, when the mother suspended its use. Had no treatment and remained free from attacks until February, 1880, when a *status epilepticus* of forty-eight hours' duration occurred; most of the spasms were bilateral, and a few involved only the left arm and leg: never bit her tongue. Early in March several attacks in a group. Paralysis has never been observed after attacks, but the child is cross and has headache after them. Most of the attacks have been nocturnal.

Recently one dizzy spell.

After this consultation, a stricter bromide treatment was attempted, but never faithfully carried out by the mother.

*Status epilepticus* occurred in June and September, 1880: many attacks limited to left side. After June attacks, she was almost maniacal for one month.

From January 21st to February, 1881 (when last seen), many seizures, most of them of mixed type, some like petit-mal; calling out, with slight shaking of both arms, staring, and pallor of face. Very unmanageable; semi-maniacal at times in last few weeks.

Family neurotic; maternal grandfather subject to violent neuralgias about the head (specific?); mother of child had convulsions from eight years, for how long a time and of what kind it is impossible to learn.

Careful examinations of the child on two occasions, nearly one year apart, gave no objective symptoms indicating the existence of what one would naturally suspect, viz., a localized lesion (tumor?) in the right hemisphere of the brain.

For many months the physician in charge of the child, and the consulting physician, a man of great eminence, ignored the truly epileptic nature of the child's attacks, asserted their curability, and treated the child carefully for worms and for disorder of the digestive organs.

Case VIII.—Jas. W——, aged twenty-one years, seen October, 1878. Health has been good; denies masturbation, sexual excess, and syphilis. Married fifteen months ago, and has one healthy child.

First epileptic attack occurred three years ago, and the second after an interval of eighteen months.

Since the second attack, has had seizures with increasing frequency: thirteen in the last twelve months. Last seizure occurred yesterday. The attacks have all been nocturnal, occurring at from one to five o'clock A.M., and characterized by severe spasm, biting of the tongue, and passing urine in the bed, and followed by heavy sleep. The next morning has headache.

Did not have treatment until after attacks became frequent.

This case is interesting as showing the real significance of a first epileptiform seizure in a non-syphilitic and non-uræmic adult. The patient had epilepsy just as much after the first attack as he did when the seizures recurred every two or three weeks, and the proper time for successful treatment would have been after the first attack.

CASE IX.—Mary L——, twenty-two years, seen October, 1880. When only three weeks old, had a series of convulsions in the course of one week, followed by cyanosis. Afterward was subject to "screaming spells," in which she threw her body forcibly backward.

From fourth to eighth year no attacks of any kind. When eight or nine years of age had attacks of unconsciousness, in which the eye rolled up, the appearance was statue-like, with a cataleptic state of the limbs. These attacks have occurred daily since; on some days she has had as many as ten or twenty seizures.

Menstruation occurred at thirteen years, but the attacks continued unchanged. Went to school at usual age, but study was abandoned in twelfth year, nominally because of "indigestion," but in reality because patient's mind was feeble; she was to a degree imbecile.

In the last fourteen months has had five attacks of grand-mal; the first in August, 1879, the last one about two weeks ago. In these severe attacks she did not bite her tongue. Has had fewer attacks of petit-mal since these convulsions.

Patient states that she has no aura; as to frequency of petit-mal, she thinks that she may have had as many as one hundred "spells" in one day.

The existence of neuroses in the family is denied. The cause of the second series of epileptic phenomena (from eighth year) appears to have been masturbation, which was practised from the sixth or seventh year until some time after attacks set in. Positively denies self-abuse in the last few years.

This young woman's father was a physician, recently deceased, but the epileptic nature of the disease was not recognized until the convulsive attacks of 1879–80.

CASE X.—Mrs. C. A. R., aged twenty-eight years; seen December, 1878. Was a robust, healthy girl; menstruated in her thirteenth year. In the same year had a very severe attack of typhoid fever, followed by great debility of body and mind. Sexual feeling, which had already been experienced by the patient, disappeared and has never returned. Menses continued nearly regular. At an uncertain time (not long) after the fever, began to have petit-mal of the faintest kind; a mere momentary blurring or loss of consciousness, at frequent, but irregular intervals.

Married at eighteen, and has borne children. Petit-mal has continued occasionally. At about twenty-one had a first convulsion one morning after rising; she frothed at the mouth and bit her tongue. In about two months had a second equally severe attack, and a third one thirteen months later. Then was given bromide and valerian, but irregularly. Four years passed without any convulsions, but she continued having petit-mal at intervals of a few days to three weeks in length.

In 1876 was in Europe travelling, not eating much and using stimulants; had an attack in the summer (grand-mal), and three since. The last one occurred six weeks ago, in the night. Petit-mal occasionally.

In reality this patient was epileptic some twelve years without having a proper diagnosis and treatment.

CASE XI.—Lizzie B., aged twenty-seven years; seen July, 1880. Since the age of eleven or twelve years has had peculiar attacks, consisting of a sensation of something starting in the epigastrium and rolling up to the throat, lasting only a few seconds, not accompanied by tears or other emotional disturbance. Thinks that her consciousness is not lost; calls for hartshorn. At first these attacks occurred once in three or six months; in the last year has had them every two or three weeks. The true nature of these attacks was ignored, though patient was under the constant supervision of a good physician.

Menstruation established at fourteen years (long after first petit-mal); irregular and with pain.

In March, 1880, patient had a regular convulsion, and a slighter one a few days ago. These attacks are described by patient's sister; she herself thinks that they were "long faints." [This shows how much reliance is to be placed on her other statement that she preserves her consciousness in the slighter seizures.]

It was only after the spasm in March that a bromide treatment was instituted. Patient went home in October.

Since January, 1881, quite a number of attacks of grand-mal.

CASE XII.—Dr. ——'s son, aged twenty-two years, November, 1880. Patient not seen; statement made by the father.

From twelfth to sixteenth years had occasional "frightened spells" or "faint spells." No details.

In sixteenth year first recognized epileptic attacks; usually nocturnal; grand-mal at intervals of one or two months. Four attacks in the last four months. In attack spasm begins on the left side of the body, and is most severe on that side; the tongue is bitten, and there is frothing at the mouth.

In 1878–79 had no grand-mal (interval of nearly two years).

At age of six or seven years fell on the ice, striking on his forehead; lost consciousness and vomited.

Masturbation begun in eighth year, probably before petit-mal, which it appears began before the twelfth year, as stated in commencement of the history.

The father, though a practising physician, paid no special attention to the petit-mal, and attributed the first convulsions to late suppers and gastric irritation in general.

(To be continued.)

THE *Arkansaw Doctor* is a monthly medical journal, published in Harrisburg, Ark., and edited by L. J. Collins, M.D. The first number was issued June, 1881, and the editor gives no excuse for its appearance. This is a new and notable departure from "supplying a want long felt," and we wish the youngster success. The present number contains many good things.

## EXTIRPATION OF LOWER END OF RECTUM AND ENTIRE PROSTATE GLAND FOR SCIRRHOUS CARCINOMA.*

By CHARLES K. BRIDDON, M.D.,

NEW YORK.

The following is the history of the case, as taken from the notes of Dr. J. W. Stickler, house surgeon to the Presbyterian Hospital:

A male patient, sixty-nine years of age, entered the Presbyterian Hospital, February 28, 1881.

*Family history of phthisis; none of cancer.* Thirteen years ago patient had necrosis of right femur; had gonorrhœa twice forty years ago; three years ago experienced a sharp, cutting pain near the root of his penis; ten months ago micturition became painful, and caused a burning sensation along the entire course of the urethra; since last June has had griping pain in the rectum and in the territory of the penile portion of the pudic nerve. Fæces were passed without pain. Had retention of urine last December, relieved by hot hip-baths. During the last five months there has been constant difficulty in passing his urine; he has found it necessary to strain before the urine would flow, and after the bladder has been apparently emptied there would escape a few drops of urine. Has had pain in the region of the prostate gland, radiating into his back and down the thighs. During the last two months has been obliged to void his urine about every half-hour during the day, and every hour during the night. Three months ago he discovered an ichorous discharge from his rectum. Defecation has caused him much pain, especially when the fæces have been solid. He has a tearing pain in his rectum now, and lancinating pain in his loins. Fæces are somewhat flattened, and at times entirely covered with a foul, ichorous fluid. Bowels constipated. Pressure in the perineum over the prostate causes pain. Passes his urine every fifteen minutes. Has to strain now more than two months ago; sometimes the urine stops flowing very suddenly, and then, after the passage of some stringy mucus, it begins to flow again.

*Examination of urine.*—Specific gravity, 1008; color, light straw; reaction, alkaline; odor, foul. Amount in twenty-four hours, sixty ounces. Sediment, yellow and stringy.

*Microscopical examination.*—Numerous pus-corpuscles; bladder-epithelium; no casts.

*Chemical examination.*—Albumen, 1 to 6 per volume.

*Examination of urethra.*—An obstruction was found at the meatus, admitting a flexible, olive-pointed bougie No. 3. Another obstruction was found at the bulbo-membranous portion, admitting a No. 1 bougie.

*Rectum.*—An oval ulcer was found on the antero-lateral wall, immediately within the sphincter ani. It was about two inches in length, craterous in its conformation, and of almost cartilaginous consistence. The deepest portion appeared to be continuous with the prostate, and apparently was incorporated with the gland. The patient was told the result of the examination, and that it might be necessary at the operation to excise a portion or all of the gland, and that in such an event he would be obliged to pass his urine through the perineal opening.

*Operation,* March 11th, 3 P.M., by Dr. Briddon.—Patient etherized. An attempt was made just previous to the operation to pass an instrument into the bladder, the meatus having been divided, but the effort was unsuccessful. An incision was made from a point over the tip of the coccyx to the posterior extremity of the anus, thence around the margin of that aperture and along the medium raphe to the base of the scrotum.

These incisions, carried through the superficial and deep fascias, divided the ano-perineal region into lateral halves, which were retracted by means of strong silk. The levator ani was then divided on either side, and an attempt was made to separate the lower portion of the rectum from a more solid mass that appeared to be continuous with it, and which projected upward and forward in the direction of the pubic arch. It required long and powerful efforts to separate this portion from its deep connections, and it was accomplished principally by the fingers, aided occasionally by the curved scissors. In the concluding part of the operation the finger entered the bladder, and it was supposed that the detached mass was formed out of a part of the prostate. By further traction the whole mass was drawn down outside the external wound. The gut was divided in sections, each vessel being tied as it spouted, and no further difficulty was encountered. There was but little hemorrhage, considering the magnitude of the operation.

Retraction of the flaps permitted an accurate inspection of the large chasm exposed. The roof was formed out of that portion of the visceral layer of the pelvic fascia that lines the upper surface of the levator. Centrally was seen the small circular opening of the neck of the bladder, bounded on either side by the seminal vesicles; these bodies had a suspicious feeling of induration that led those of my colleagues who examined them to express the opinion that they also were invaded by the same deposit that existed in the rectum; there was no discoverable rent in the peritoneum, and no oozing of blood. The parts were left entirely open, with directions for frequent irrigation with a disinfectant. On examining the parts removed, it was found that the strong efforts which had been found necessary to draw the parts down, had separated the lower end of the rectum from the solid mass referred to in the details of the operation; that the rectal portion of the tumor was considerably broken up by the manipulations, and that the solid portion was formed out of the prostate gland enlarged to about the dimensions of a billiard-ball.

March 11th, 8 P.M.—Patient recovered well from the effects of the ether and operation. Was conscious and asked for things ten minutes after being taken to the ward.

Ordered ℞. Sol. morph. sulph., U. S. P., ʒ ij.; spts. vini. gallici, aqua, āā ℥ ij. M. Sig.—ʒ every half-hour; also milk ʒ j. every half-hour.

March 11th, 10 P.M.—Pulse, 140; temperature, 98° F. 11 P.M.—pulse, 120; temperature, 98½° F. 11.30 P.M.—pulse, 109; temperature, 98¼° F. Respiration regular and deep; but little oozing; no pain when quiet.

March 12th, 9.30 A.M.—Temperature, 98½° F.; pulse, 104, and quite strong. Respirations normal. No hemorrhage. Slight pain in hypochondriac region. No abdominal distention or tenderness. Passes urine freely through wound. A solution of carbolic acid 1 to 40 injected into the wound three times a day. Takes two teaspoonfuls of brandy with an equal quantity of water every half-hour. Takes milk and beef-tea, two ounces every two hours.

* Paper read before the New York Surgical Society.

Hot bottles kept in the bed, next the patient, during the day.

March 12th, 8 P.M.—Pulse, 115, not very strong. Respirations somewhat irregular. Ordered brandy, ʒ j. every fifteen minutes till further orders. 11 P.M.: pulse 128 and very weak. Respirations, twelve per minute and very shallow; hands and arms cold, feet and legs warm. Slight pulmonary œdema. Applied six dry cups to chest, gave brandy ʒ ij. every half-hour.

Dressings changed; no hemorrhage; ordered milk ʒ ij. every half-hour. 3 A.M.—Patient says he feels very comfortable.

March 13th, 8 A.M.—Pulse 130, very compressible; Temperature, 98½° F. Respiration, 14; patient very restless and drowsy; pulmonary œdema more marked. Gave brandy, ♏ xx. hypodermically, followed by ʒ ij. per ounce of milk and beef-tea every fifteen minutes. 9.30 A.M.—Temperature, 100½° F. Pulse 140 and very weak. Respiration, 12. Gave tr. digitalis and brandy, āā ♏ x. hypodermically, repeated in twenty minutes. 9.40.—Pulse somewhat stronger, but just as rapid. Gave brandy per orem, ʒ j. every twenty or thirty minutes.

March 13th, 10 A.M.—Tr. digitalis and brandy, āā ♏ x. hypodermically. 10.15 A.M.—Pulse, 138; respiration, 12; temperature, 99½° F. 10.40 A.M.—Tr. digitalis and brandy, āā ♏ x. hypodermically. 11 A.M.—Pulse, 128 and stronger; respiration, 14; answers questions imperfectly. Has considerable dyspnœa. Abdomen not sensitive or tympanitic. No hemorrhage. 12.30 P.M.—Pulse, 130; respiration, 11 and sighing. Temperature, 98½°; will not answer questions. 2 P.M.—Pulse, 153, and very weak. Cold, clammy hands, warm feet. 3.25.—Pulse, 160; respiration, 11, jerking. Hands and arms cold. Comatose. Died.

Necropsy, nineteen hours after death, by Dr. William H. Porter, Curator of the Hospital. Rigor mortis well marked. Body emaciated.

*Pericardium and heart.*—One drachm of fluid in the pericardial sac. One milk-patch on the anterior surface of the right ventricle. Slight adhesions round the base of the heart to the adjacent parietal pericardium. There was a small amount of fluid blood in the left cavities, with considerable coagulum in the right cavities. The aorta was extensively atheromatous. Weight of heart twelve and one-half ounces. Valves free and sufficient.

*Pleura and lungs.*—The left organ was free in the pleural sac. Portions of this lung were collapsed (apneumatosis). The right lung was adherent to the chest-wall by old fibrous bands, under which the lung was consolidated and indurated—so-called fibrous phthisis. There was some apneumatosis of the upper lobe of this lung, with hypostatic congestion and œdema of the most dependent portions of the inferior lobe. The left lung weighed eleven ounces, the right thirty ounces.

*Abdominal cavity.*—*Spleen* soft and flabby; weight, four ounces. The *liver* appeared normal; weight of organ, forty-eight ounces.

The pelvic cavity and genito-urinary tract presented many points of interest. No evidence of peritonitis. The contents of the pelvic cavity were removed by passing a knife close to the bone and cutting the pelvic contents from its bony attachment. The kidneys and ureters were removed attached to the bladder.

The anal orifice presented, instead of the normal appearance, a large, elliptical ulcerating wound four inches long, in the antero-posterior diameter. This opening communicated with a large, irregular cavity left after removal of a part of the rectum new-growth and the prostate gland. The superior limit of the cavity was bounded by the cut end of the rectum part of the neoplasm, the neck of the bladder to the right, and posteriorly by the pouch of Douglas, but to the left of the median line, between the bladder and rectum, there was an opening into the peritoneal cavity, leaving a communication between the cavity in the pelvic fossa and the peritoneal sac. Behind this opening, to the left of the median line, there was a triangular mass of the neoplasm left.

*Microscopical examination* of this indurated mass gave evidence of *scirrhous carcinoma*, but the fibrous elements made up the mass of the neoplasm with non-striated muscle fibres, widely interspersed, with only an occasional alveolar space filled with epithelial elements.

The bladder was contracted and hard; external circumference six inches; the walls one-half inch thick; the internal diameter from neck to fundus one and one-half inch. It felt, when first removed, of stony hardness, as if infiltrated by the new-growth, but close examination showed it to be from any change except those of chronic cystitis with atrophy.

The seminal vesicles contained a few round masses of a calcareous nature.

The ureters were distended with purulent fluid, and at the upper limit of the left ureter there were two valve-like projections into the lumen, which rendered the passage of a probe into it from the pelvis of the kidney extremely difficult. The right ureter was also distended with purulent fluid.

The pelves of both kidneys were distended with a thick, purulent fluid, and both glands were studded with many small abscesses, varying in size from that of a millet-seed to a large pea, or even larger.

*Microscopical examination* of the kidneys showed that some portions were nearly normal, the only noticeable change being a slight, cloudy swelling of the epithelia; in other portions there were marked collections of pus-corpuscles among the tubules, without any limited wall, thus forming minute diffuse abscesses; in other portions small cavities were formed, evidently due to the melting down of the tubules, filled with pus-corpuscles, so that a number of the tubules were entirely divided, destroyed, and replaced by pus. These cavities containing pus were surrounded by a zone of pus-corpuscles diffused among the renal elements.

REPORT UPON THE MASS REMOVED AT OPERATION.

This mass was composed of the anal orifice and rectum, prostate gland, and a neoplasm which lay to the left and between the prostate and rectum. The prostate gland measured six inches in its greatest circumference. The urethra passed through the anterior lobe about one-third nearer the anterior than the posterior surface. Connecting with this anterior lobe, and pointing downward and backward, were three smaller lobes representing a middle, right, and left lateral lobe.

The anal orifice appeared nearly normal, but one-half inch above the orifice there was a ragged edged ulcer, one inch in diameter and one-half inch deep. This ulcerating cavity, surrounded with an indurated mass (the new-growth), extended forward and to the left of the median line, and appeared to be continuous with the substance of the left half of the prostate gland. The remaining portion of the rectum was normal. The upper limit of the growth, which had some of the surrounding

tissue attached, was very irregular in outline. Upon the outer border of this neoplasm there were several rounded nodules—probably infiltrated lymphatic glands; otherwise, the surrounding glands of the pelvis were not involved.

*Microscopical examination.*—The neoplasm close to the ulcer showed marked evidence of carcinoma of the scirrhous variety, in the shape of wide bands of dense fibrillated connective tissue, forming alveolar spaces, irregularly packed with large, nucleated, epithelial corpuscles. The fibrous element was the predominating feature, with occasional non-striated muscle-fibres. Although the new-growth appeared to have extended into the prostate gland, careful microscopical examination failed to detect any evidence of carcinomatous disease in the prostate. The neoplasm appeared to be separated from the gland by a layer of fibrous tissue, probably the capsule of the gland.

*Remarks.*—In this case the prostatic obstruction was the most prominent feature, and it was evident that it would soon culminate in retention. A careful consideration appeared to warrant an operation that would anticipate that condition, and, as it appeared that the prostatic tumor was an outgrowth of the one in the walls of the rectum, it was judged best to attack both at once. In the operation it was found impossible to isolate the one from the other. A very careful inspection of the operation-wound was made after the removal of the diseased mass, and no wound of the serous sac was found; and that which was found at the autopsy, certainly had no influence on the result.

The mode of death was such as is found in cases of blood-poisoning and the advanced stage of surgical kidney. Pyelo-nephrosis will be recognized as sufficient cause for death, as is well known. Microscopic and chemical tests of the urine failed to give evidence of such condition. In repeated examinations no elements were found that threw any light on the condition of those organs.

## ON THE INDICATIONS FOR THE TREATMENT OF NASO-PHARYNGEAL CATARRH.

By ANDREW H. SMITH, M.D.,
NEW YORK.

In the discussion of the much-discussed subject of naso-pharyngeal catarrh, there seems to me to have been a lack of precise statement of the indications for treatment. Different procedures have been recommended with the general and vague object of suppressing the discharge, without a definite statement of the manner in which they are expected to contribute to that result. A step in advance will have been made when we have an exact idea of what is to be done, so that we may select the best method of doing it.

The indications for treatment, it appears to me, may be concisely formulated as follows:

*First.*—Keep the parts clean.

*Second.*—Remove all sources of irritation resulting from occupation, residence, climate, etc.

*Third.*—Enforce attention to hygiene and to the general health.

*Fourth.*—If there is obstruction to nasal breathing, remove the obstruction.

*Fifth.*—If there is ulceration, use strictly local applications, with a view to healing.

*Sixth.*—If there is hypertrophied glandular stricture yielding excessive secretion, remove the hypertrophied portion.

*Seventh.*—If, after the above indications have been fulfilled, there is still hyperæmia, use mild astringents and sedatives, and such constitutional treatment as is thought to be indicated.

*Eighth.*—Cease treatment the moment there is no longer a definite indication for it.

As to the first three indications, the reason for them is too obvious to require comment.

The fourth indication, relating to obstruction to nasal breathing, is of very great importance, chiefly, as I think, for a reason which I believe has not heretofore been brought forward. I refer to the effect of nasal stenosis in causing hyperæmia of the membrane behind it, owing to the rarefaction of the air with each inspiration. The influence of this diminished air-pressure behind the obstruction upon the development of the bony and cartilaginous structures of the nose in early life has lately been insisted upon by Dr. Roe, but he has overlooked the fact that all the tissues subjected to the action of this partial vacuum must suffer a proportionate congestion as certainly as the skin under a cupping-glass. From congestion to hypersecretion is but a single step, and here I think we have a key, not only to the persistence of the discharge in many cases, but to the prompt abatement of it which often follows relief of the stenosis.

The fifth indication, relating to direct applications to ulcerated points when practicable, should discourage the use of strong irritating solutions, sprays, or powders to the whole mucous surface, in order to heal ulcerations of a limited portion of it.

The sixth indication, as to hypertrophied glandular tissue, requires a discrimination between that which produces hypersecretion and that which does not. The former should always be removed, the latter never unless it obstructs nasal breathing, which would bring it under the fourth head.

If the preceding indications have been fulfilled, the one relating to the use of astringents and sedatives will seldom be present for any lengthened period. Still their use for a limited time will often hasten the return of the vessels to their normal calibre. As to the value of constitutional treatment in non-specific cases, nothing is as yet definitely settled.

The last indication is far from being the least important. Continuing random local treatment may perpetuate the disease indefinitely, and when the cure has reached a point at which we no longer know just what we expect our remedies to do, it is time to lay them aside and give nature an opportunity to complete the work.

Night-Calls and a Jealous Wife.—A physician is suing, at Shelbyville, Ind., for a divorce from his wife, on the ground of cruel and inhuman treatment. Having a large practice, he is frequently called out at night. His wife, being jealous, refused to believe that all his absences from home were professional, and demanded that he should stay in of nights. He said his patients would not stand neglect. Then she adopted the plan of taking poison whenever he had a night-call, thus compelling him to remain and doctor her. She swallowed a deadly drug in this way several times, and her life was saved with difficulty. The husband claims that such conduct is a just cause for divorce.

## A CASE OF STRICTURE OF THE URETHRA,

### With Polypi of Membranous Portion—Removal of Polypi by the Polypi Guillotine.

By HERMAN G. KLOTZ, M.D.,

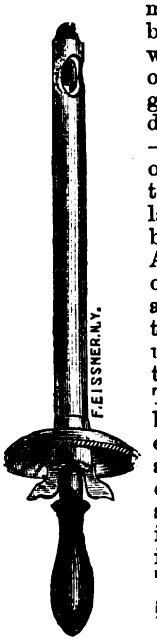
ATTENDING SURGEON, NEW YORK GERMAN HOSPITAL, DEPARTMENT FOR SKIN AND VENEREAL DISEASES.

Henry P——, aged twenty-six years, a grocer, a native of Germany, came to my office last August. He had contracted gonorrhœa, for the first time in his life, about three years ago; since that time, the discharge from the urethra has continued more or less until now. He is in good health otherwise; never had chancre or syphilis.

On examination, a stricture was found about thirteen centimetres from the meatus externus, an olive-pointed bougie, No. 14 Charrière, only being passed, steel bougies of the same calibre causing slight hemorrhage. After a few weeks of gradual dilatation by bougies, steel bougie No. 27 Charrière could be passed easily to the bladder; smaller olive-pointed bougies, however, were always arrested near the seat of the stricture. At the same time the discharge showed very little abatement. To ascertain the cause, I resorted to the endoscope. After several fruitless examinations, I discovered the presence of polypoid growths at a distance of thirteen centimetres from the meatus. Application of caustics (nitrate of silver, liquor ferri, etc.) having proved unsuccessful for the destruction of the polypi, I had to think of other means for their removal. Circumstances prevented the patient from continuing the treatment until February of the present year. Having mentioned the case at the January meeting of German physicians, Dr. F. Zinsser kindly offered me his assistance, and the use of his more perfect endoscopic instruments. With his aid, the polypi were found to be distributed quite numerously over the length of about one centimetre of the membranous urethra, and, during several sittings in February and March, about a dozen of them were removed, varying in size from a canary-seed to a pea. Even now, after having been kept in alcohol for several months, the largest piece measures four millimetres at the base, and six millimetres in height. After that, no more polypoid growths could be detected, but the affected part of the urethra showed the mucous membrane considerably swollen, and of a velvety appearance; at some places small excrescences, which bled very readily, seemed to indicate the former seat of the polypi. Under the application of caustics and astringents (nitrate of silver in substance, or in twenty per cent. solution, tincture of iodine, etc.), the mucous membrane is returning slowly to its normal condition, the seat of the former stricture being recognized by the scar-like, perfectly white appearance of the mucous membrane of the upper wall of the urethra, immediately in front of the seat of the polypi.

The removal of these growths was effected partly by a wire snare, which, except as to size, is very similar to Blake's wire snare for the removal of polypi of the ear. At a short distance from the meatus externus it works quite well, but greater difficulty is experienced at a distance of twelve and thirteen centimetres. On account of the soft walls of the urethra caving in immediately on withdrawal of the endoscopic tube, there never is a clear space wherein to manipulate the snare, so as to bring it around the base of the growth. To overcome this difficulty, I had a new instrument, the polypi guillotine, constructed by Mr. F. Eissner, of New York, which is essentially a modification of the "polypenkneipe" described by Grünfeld ("Die Endoskopie der Harnröhre und Blase," Deutsche Chirurgie, No. 51. 1881).

It consists of two concentric metallic endoscopic tubes, the calibre of which is 25 and 22 respectively of Charrière's scale. The ocular ends bear differently shaped handles, which allow the revolving of the inner tube without obstructing the view. Beginning four millimetres from the visceral end, both tubes have removed from their walls an elliptical-shaped segment, of somewhat less than ninety degrees, the conjugate and transverse diameter being 8 and 6 respectively —6 and 5 millimetres. The edge of the elliptical opening of the inner tube, the visceral extremity of the latter for about four centimetres, being made of steel, is ground sharp. After having closed the elliptical openings, by turning the inner tube as indicated by marks on the handles, the instrument is introduced into the urethra, by means of a common obturator, beyond the seat of the polypi. Then the position of the instrument being ascertained by inspection, the elliptical apertures of the two tubes are made to correspond. On withdrawing the instrument, in slow, screw-like manner, the polypi come in sight through the elliptical opening, as soon as their seat is reached. They are easily distinguished by their generally somewhat lighter color and by their shape. Sometimes they make their appearance quite suddenly, falling into the tube as into a trap. By revolving the inner tube to its former position, its sharp edge cuts through the base of the polypus, thereby separating it from its seat. On withdrawal of the whole instrument, the polypus is safely removed from the urethra. Pain is very inconsiderable; bleeding seldom requires any particular applications. After a few days the operation can be repeated.



I have taken great pains to ascertain that no part of the healthy mucous membrane can be cut off by this instrument. In good light, especially in sunlight, which I prefer for endoscopic purposes to any artificial one, when it can be had, I could see the mucous membrane bulge in considerably, but give way before the revolving inner tube, without ever being caught or injured by the sharp edges. Some difficulty is experienced at first, by seeing parts of the interior surface of the urethra, by the elliptical opening as well as by the visceral end of the tube, which can be distinguished only in very good light. To obviate this, Dr. Zinsser has suggested a closure of the instrument at the visceral end, thereby giving it the appearance of the point of a catheter; this would at the same time do away with the obturator. But to allow thorough cleaning of the instrument it would be necessary to have the visceral tip made removable. Finally, using the outer tube alone as an endoscopic tube, polypi could be isolated completely from their surroundings, thus considerably facilitating the application of a wire snare around their base. It might also be used for isolation and safe cauterization of otherwise diseased circumscribed parts of the mucous membrane.

222 East Nineteenth Street, New York.

# MILK.*

By E. F. BRUSH, M.D.,

MOUNT VERNON, N. Y.

The position that milk occupies in scientific works at the present day is very unsatisfactory to the busy practitioner. Almost every author gives a different analysis, and many of the phenomena remain still unexplained. The lactometer seems to be merely a source of dispute, and is in no way accurately scientific. The latest work on "Milk Analysis"—that of Wanklyn—lacks precision in detail; he leaves out albumen in his analysis—a very important constituent to be considered—and he masses together all the salts as milk sugar. This seems to me an unsatisfactory method, for it is a fact regarding these substances, that on the proportion existing between them and the caseine the quality of the milk depends. I have previously stated in the *New York Medical Journal* the fact that, as caseine decreases, the milk, sugar and the albumen increase, and *vice versa*. By ascertaining these we can determine the wholesomeness of any given specimen of milk.

I am engaged in simplifying the analysis of milk. The process I adopt is as follows: I have a water-bath arranged with three funnels and one flask. In the first funnel I place milk, having previously coagulated the caseine with chloride of sodium; I boil the filtrate and throw it on the second funnel to obtain the albumen. The second filtrate I precipitate with Fehling's solution, to ascertain the amount of sugar. From the residue in the first filter I wash the fat with ether. This ethereal solution I place in the flask. I wash the caseine with pure water, thus removing the salt. I then start my water-bath, which dries the three filters and expels the ether, leaving the fat. When these are dry, all that is necessary is to weigh the results.

As the other salts contained in specimens of milk are found to occur in only very small proportions, and, as their significance thus far is of slight importance, I have not attempted to ascertain them with strict accuracy.

In testing with the lactometer, we are led astray both by the presence of water and by an excess of cream. I obviate these difficulties by first coagulating the caseine, and then taking the specific gravity of the filtrate. This, as you can see, removes both the sources of error. There is, I think, only one possible source of error in taking the specific gravity this way—that is, the addition of salt may keep up the specific gravity of the serum. This can be eliminated, if one suspects its existence, by precipitating the chloride with nitrate of silver. Of course a considerable amount of labor is required to obtain a standard. I have not done so. Having dealt in milk for years, I have relied on this test, and as our ingenious milkmen have not discovered it, I have not thought it necessary to guard against a fraud which might be perpetrated if the test were known.

So much, then, on the modes of testing. But, in examining milk, we must consider another point, that is the position it occupies as a producer and distributor of disease. Compared with this acknowledged fact, simple dilution with water is of slight importance. Diseases may be conveyed by milk taken from an animal suffering from disease, or by milk contaminated in the dairy, or by contact with diseased or infected persons. There is no definite law forbidding the sale of milk from diseased animals. On reading the last Report of the Department of Agriculture, I find a statement made by a dairyman on Long Island, in which he declares to the commissioners that for twenty years he has had cases of pleuropneumonia in his herd. In this disease the flow of milk is not usually entirely suspended, and it is only lessened slightly during the first few days of active fever. When the flow is suspended, it is during the extreme heat of summer, when the disease attains its utmost violence—that is, when the animal is about to die. There can be no doubt that the milk of a cow suffering from a disease of this character must be poisonous. On analysis of milk thus diseased, I have discovered an increased amount of albumen as the only difference. Garget, an inflammatory condition of the internal substance of the udder, is another vaccine disease which causes unwholesomeness in milk. In cases of foot-and mouth disease—a disease producing in the cow aphtha, diarrhœa, and enlarged glands—Dr. Joseph Weil writes that the "raw milk produces a feverishness, swelling of the tonsils and submaxillary glands, and pemphigenous eruptions on the lips and tongue." I need not, even if time permitted, enumerate all the other diseases which infect milk. But this dissemination of disease by diseased milk is a fact which we medical men ought to recognize. We ought to bestir ourselves to procure legislation defining the duties of milk-producers as regards the health of their animals. At present the whole law seems to have been made for the pecuniary protection of corporations and herdsmen. In fact, half of the laws are enacted to protect butter and cheese factories from skim-milk and oleomargarine. It is significant that the first law passed in this State respecting milk was passed, not to prevent the Orange County Association from selling diseased milk, or for protecting the thousands of children whose food it supplies, but to prevent their agents from defrauding them. The whole tenor of the law is in the same direction. There is indeed a law saying unhealthy milk must not be sold, but the definition of "unhealthy" as given in the law is "milk from cattle feeding on distillery swill, or on any substance in a state of putrefaction." The factories are further protected by the prohibition of the sale of tainted milk, or milk kept in dirty vessels. They are also protected by a law prohibiting the sale of skim-milk. This insane law is the only definite one, except the one against the addition of water. We all know that if the same energy had been directed by the New York Board of Health against diseased milk, which has been directed against watered milk, the lives of thousands of children would have been saved. From what I have seen of the dairies in Westchester County, and from what I have learned by conversations with dairymen, I am convinced that the greatest cause of disease among infants in New York City actually arises from the use of diseased milk, and the mixture of colostrum with sound milk. This is a most serious and important subject, and utterly neglected by the law. Calves taken immediately from their mothers, "bob-veal," is denounced because it produces disease in his majesty the adult citizen. But no law prohibits the wholesale administration of colostrum to the luckless infant. In none of the numerous works that I have consulted, either scientific or intended for farmers, have I found any allusion to this evil. Thus, even the conscientious man has no warning and no guide. Many of the milkmen informed

* An essay read before the Medical Society of the County of Westchester, at the Annual Meeting, held at White Plains, Tuesday, June 21, 1881.

me that the third milking after calving was considered fit to mix with other milk. In the course of conversation I casually inquired what effect the third milking would have on a calf three months old. The farmer innocently replied, "It would probably give him the scours." This disease in the calf corresponds to cholera infantum. Last summer I attended a child suffering from cholera infantum. I proposed to give it whey, and to procure it I took some of the milk on which the child had been fed, and attempted to coagulate it with rennet. I failed utterly. I threw the specimen away and sent to the same place for some more milk. The same result ensued. I then left out the rennet, and boiled the milk. It coagulated on boiling. As this is what takes place in colostrum, the cause of the attack was plain. By changing the diet the child recovered. This would be an easy test if it were not for the fact that the colostrum is mixed in most cases with a large proportion of milk, and hence only negative results would be attained. In regard to the time when milk is fit to use after calving, I am undecided, as I am still engaged in the investigation. If I succeed in interesting medical men to procure legislation on this subject, I shall be able to give definite and scientific rules. I will say here that, according to Lehman, colostrum corpuscles remain till the third or fourth day, and occasionally to the twentieth day, and as a general rule returns when any disease supervenes after delivery, or in case the mother is attacked by any acute affection. Colostrum becomes acid more rapidly than milk, and contains less sugar. Let me beg of you not to forget this matter: we owe it to the community to protect their children. I would even go so far as to desire that every dealer in milk be compelled to take out a license, and that in every death-certificate of an infant the name of the milkman supplying it with milk be inserted. The officials of the Board of Health would thus be able to see if the same name occurred repeatedly, and to take steps to stop his sale of poisonous milk. I hope to see the day when the matter will receive due scientific and legislative attention.

There are of course other items of great importance relating to the milk of the cow. As we who use the milk belong in the animal kingdom to the non-ruminants, we have to study cows' milk as designed for the stomach of ruminants. If it were possible for us to feed children on the milk of non-ruminant animals, as the human being or ass, there would be much less difficulty attending the artificial feeding of children. Looking at it in this light, there is no doubt we could mend the matter considerably. Calves always regurgitate and chew the milk before it enters into the digesting stomach. Some people argue that milk, when drawn from the gland and kept, loses at once its vital principle, and thus seek to account for its indigestibility. To my mind this is proved to be false reasoning by the fact that the most successful stock-raisers do not allow the calves to suck. This is not from economy. I can cite a case in point. A farmer with a herd of pedigree stock, in which he took a great pride, allowed his calves to suck. They became so fat as to excite the admiration of all beholders. When the weather became hot they all died. The mode of death was peculiar. They gave a strange cry, which attracted the attention of the farm-hands, reeled round, and, before the men reached them, were dead. One after another they all thus perished. Since then the breeder has fed his calves from a trough with about half the milk from their mothers, and none have died in this manner. These breeders, I need scarcely add, are very particular about the colostrum.

From these facts I have reached the conclusion that, to feed a child properly on cows' milk, we must imitate the first process of the calf, by coagulating the caseine either with rennet or dilute hydrochloric acid, and beating up the caseine very fine. I have kept two babies, now eight months old, on milk with the caseine thus broken up, with the most satisfactory results. Even milk that is sour, if the caseine is broken up before it is introduced into the stomach, not only will not disturb it, but is more wholesome than fresh milk with the caseine unbroken. After a thunderstorm, when nearly all the milk in the community is soured, we all know how many children at once fall sick. This, I candidly tell you, can be avoided if you will coagulate the caseine before giving the milk. This phenomenon of milk-souring and sometimes coagulating immediately after the electric disturbance, has not hitherto been satisfactorily explained. I was led to the solution of the problem while engaged in the manufacture of kumyss. Having the bottles closely packed together in a large pile, I found that when one of them burst, the contents of the bottles in the immediate neighborhood always were coagulated. It seems to me, therefore, that this phenomenon is susceptible of the same explanation as the fact that water which is quiescent at a temperature much below the freezing point, will not freeze till it is jarred, and that bodies rise from the bottoms of ponds and rivers when cannon are fired. It is due to molecular change produced by atmospheric concussion, just as rain is precipitated after a battle.

In regard to some of the popular modes of feeding children artificially, I will here explain a few of them. We will first consider boiled milk. By this procedure we of course lower its nutritive value by coagulating the albumen, thus rendering it insoluble. Boiling kills the lactic germs, thus delaying the development of lactic acid. It emphatically benefits milk polluted with colostrum, and probably the coagulation of the caseine in the stomach is less rapid. From these facts it seems to be proved that, if we do not coagulate the caseine as already mentioned before introducing the milk into the stomach, or if we have milk of unknown purity, boiling is undoubtedly beneficial. The addition of lime-water or soda—a favorite method—is beneficial from the fact that coagulation takes place more slowly and that we are not apt to have the large, leathery coagulum. Last summer, while talking to an eminent practitioner on the subject of feeding infants by artificial means, he stated that one of his children was not doing well with ordinary dilute milk with sugar, and had all the symptoms of defective nutrition. He stopped the milk and gave cream diluted with water. From the very first the child improved and was kept on cream till weaned. In commenting on the case the doctor expressed some surprise, as he considered that cream contained nothing much but fats. In this he was mistaken, as the following analysis will show. I removed eight ounces of cream and carefully avoided any removal of milk with it. From this cream I removed twenty nine and one-half drachms of butter, one hundred and thirty-nine and one-half grains of caseine, eighteen grains of soluble albumen by coagulation through heat, and thirty-eight grains of sugar. The analysis proves that in buttermilk we have a wonderfully nutritive fluid. Even after the caseine is removed, the amount of nu-

trition in the whey of buttermilk is quite large. This fact is enforced by the experience of the Orkney Island fishermen. They precipitate the caseine from buttermilk by boiling water immediately after churning, and place the whey in small kegs. This they take with them on their voyage, and subsist on it for several days without other food or drink.

I do not profess to have exhausted in any way the theme I have taken for this paper. There are several other points to which I would like to allude if time permitted. Before I close, I will, however, briefly call your attention to another point, that is, the removal of the ovaries from milk cows by the operation known as spaying. If this operation were more generally adopted by the owners of dairy cows, we would avoid many of the influences which affect the value of milk. If, after a cow has calved and the flow of milk has attained its normal condition, this operation were performed, we would avoid those conditions in the cow which have a deleterious effect on the milk, such as the recurrence of the sexual desire, pregnancy, and the like. A cow once spayed will continue to give milk during the remainder of her life.

# Reports of Hospitals.

## NEW YORK HOSPITAL, N. Y.

### Service of Dr. H. B. SANDS.

#### LATERAL LITHOTOMY.—THE THIRD OPERATION FOR STONE PERFORMED UPON A CHILD SIX YEARS OF AGE.

This operation, performed December 4, 1880, was interesting because it was the third one to which the patient, a boy of six years, had been subjected for the removal of vesical calculus. It is reported that at the age of eight months he showed signs of stone in the bladder. He was in the habit of pulling at his prepuce, and suffered from incontinence of urine. On the 17th of July, 1877, median lithotomy was performed, the stone requiring crushing before it could be removed. Six months after this, symptoms of calculus again reappeared, and in October, 1878, another large stone was removed, dark-colored and smooth, according to the father's statements. For a year following this relief was complete, but then signs of stone showed themselves once more. The patient had a history of occasional attacks of cystitis. Diagnosis in this instance was verified by touching the stone with the sound in the bladder and the finger in the rectum.

#### CARBOLIC ACID POISONING AFTER AMPUTATION OF THE THIGH.

This patient had been subjected to the operation of amputation of the thigh for ununited fracture of the femur. For five days after the operation the urine was green in color, an effect due to the absorption by the wound of carbolic acid, used in accordance with the antiseptic method of operating.

#### DEATH RESULTING FROM EXTERNAL URETHROTOMY.

A death was reported resulting from an operation performed October 16th, for the relief of an urethral stricture in an old man. The patient came to the hospital with a fistula in the perineum, which fistula had contracted, gave trouble, and rendered an operation necessary for his relief. The injury occurred forty years prior to his admission, and was the result of an accident, the man falling from aloft and striking his perineum on a plank. The continuity of the urethra was destroyed. He was operated upon by the distinguished Sir Benjamin Brodie, but without permanent success. Last summer the opening in the perineum contracted, and he was forced to use a catheter. After a while this mode of relief failed. He was sixty years of age, a fact which prompted the operator not to subject him to the operation of perineal section proper, but merely to pass a tunnelled sound into the fistula and enlarge the latter sufficiently. The incision was minute, not important in situation, and there was every reason to believe that the operation would be successful. Shortly after the patient had a simple nervous chill. The orifice was allowed to remain undilated until October 20th, on which day several instruments were passed through the orifice into the canal to the extent of half an inch. There was then no reason to believe that anything serious would happen. On Thursday, October 21st, at five in the afternoon, the patient was in a state of collapse. The abdomen was distended, and a catheter passed into the bladder revealed the fact that that viscus was nearly empty. The patient had not passed water since ten o'clock of the preceding night, and it was therefore inferred that he had suppression of urine. He was given a hot-air bath, stimulants and digitaline were administered, and cups were applied over the kidneys. These procedures proved unavailing, and he expired half an hour later. He died of syncope, and the autopsy failed to discover any other cause of death than fatty degeneration of the heart. Nothing was found in the abdomen and nothing in the pelvis to explain it. Dr. Sands referred to this patient in order to explain that very trifling operations upon the urethra may be followed by disastrous results. He also mentioned another case, which is interesting in this connection. In 1879 he was consulted by a gentleman from Curaçoa for a deep-seated and close stricture of the urethra, upon which he had operated eight or nine years before by dilatation. The gentleman was then told to use a catheter, which he, however, neglected to do. He tried several operations, and came back to Dr. Sands with letters from his surgeons, warning any man against repeating them, on account of the disastrous results liable to follow in his particular case. Dr. Sands finally decided to perform an operation, which he did by inserting the urethrotome, and dividing the stricture without difficulty. For twenty-four hours the patient seemed to do well, but then serious symptoms appeared. He had a chill, and ceased to pass urine, delirium came on, the pulse was rapid and feeble, and for three days the man's life was in danger. He finally recovered, though his constitution was much shattered.

---

### Service of Dr. R. F. WEIR.

#### URETHRAL FEVER—THE USE OF ACONITE AND MORPHINE.

A case of urethral fever was alluded to by Dr. Weir. It was of that form which occurs when the urine passes over the cut surface, for the first time, rarely before. In such instances the temperature may rise to 104°, 105°, or 106°, rapidly falling the next day. To prevent this rise, aconite and morphia are to be given, in doses of three to five minims of the former to one-eighth of a grain of the latter. This is to be repeated after a lapse of two hours, and, if necessary, a half dose may be given at the end of two hours

more. This is done because the fever is nervous and due to irritation communicated from the wound to the nervous plexuses supplying the kidney. Dr. Weir's experience with quinine in these cases has been rather negative.

ESMARCH'S OPERATION FOR CONTRACTION OF THE JAW.

The patient was a woman who several years previous had fallen, striking upon the chin and left side of the face, but not breaking the skin. As a result of this accident extensive inflammation took place, and finally cicatricial contraction interfered seriously with the separation of the jaws, necessitating the removal of several incisor teeth in order that she might be able to take thick food. In 1878 the woman entered a hospital, where she was subjected to a variety of treatment, such as incisions into the cicatrix, and the separation of the jaws by means of forceps. Only temporary relief was, however, afforded. Becoming discouraged, the patient entered another hospital, where the cheek was split, a procedure which was followed by a reforming of the cicatrix. Dr. Weir proposed to make a false joint and to take away enough of the lower jaw to secure non-union. Accordingly an inch and a half of bone was removed from the posterior part of the horizontal portion. The operator deemed it best to leave no cicatricial bands, as they would confine the joint. After the operation, it was possible to introduce two fingers into the patient's mouth. The residual contraction was due to disuse of the normal parts. The further progress of the case was favorable. Three weeks later the patient could open and shut her mouth, and exercise a firm grip upon a piece of rubber placed between her teeth. She was rather weak, owing to the fact that she had been confined to a diet of milk and slops for so long a time. Dr. Weir was confident of a final satisfactory result.

REMOVAL OF THE TESTICLE FOR ROUND-CELL SARCOMA.

February 12th.—The patient's age was twenty-nine years. Nearly all his life he thought he had had an enlarged testicle, but this did not give him any trouble until last October, when it increased greatly in size, became painful, and prevented him from sleeping. Three and a half weeks previous to date, the lower portion of the testicle became reddened, ulceration took place, and a mass protruded which was about the size of a pigeon's egg at first, but grew to be as large as a goose's egg. Four years prior to his admission he had acquired syphilis, consequently, at first sight, it was thought that this might be a case of syphilitic testicle, with a hernial protrusion through the ulcerated portion. Even before this idea was given up, it was decided to remove the organ. A portion of the growth was submitted to the pathologist, who declared the disease to be round-cell sarcoma, a rare affection of the testicle. In this case the absence of enlarged glands in the groin spoke against cancer. The scrotum having been laid open, the cord was reached and tied *en masse*, and the testicle and growth enucleated. Dr. Weir stated that tetanus does not occur when the ligature is passed around the whole of the cord.

---

How to Tell the Age of an Egg.—In a solution of common salt, one gramme to one litre, says *El Médico Práctico*, an egg a day old will sink to the bottom, one two days old will descend to half the depth of the liquid, and an egg older than this will float.

# Progress of Medical Science.

Pilocarpine in Scarlet Fever and Diphtheria.—An extended article on this topic, by Demme (*Jahrbuch für Kinderheilkunde*, vol. xvi., pts. 3 and 4), begins with some general remarks on the administration of pilocarpine, which may be summed up as follows:

*First.*—The conflicting accounts, given by different observers, as to the action of this drug, are attributable to its contamination with jaborin, a second alkaloid obtainable from jaborandi, and which, according to Harnak and Meyer, resembles atropine in its physiological action, while the effects of pilocarpine are more like those of nicotine.

*Second.*—The initial dose by subcutaneous injection, up to the tenth year, is 0.005 gramme; children less than one year old should not receive more than 0.001 to 0.0025 gramme. If well borne, the dose may be repeated several times a day, and may even be increased. The dose for internal administration should be two or three times as large as the above-mentioned, dissolved in fifty to seventy-five grammes of water, and should be given in mucilage, or with the addition of other suitable drugs, when there is a tendency to diarrhœa.

*Third.*—When very prompt action is required, as for example in uræmia and croup, pilocarpine should be injected hypodermically. In other cases it may be given by the mouth or the rectum, and in divided doses, especially when prolonged action is desired.

*Fourth.*—Hypodermic injections of pilocarpine are frequently followed by vomiting and symptoms of collapse. These may be prevented by the previous administration of cognac brandy, wine, strong coffee or tea, or an injection of sulphuric ether.

*Fifth.*—There is no danger to the heart from ordinary doses of pilocarpine, but when quantities of more than 0.01 are given several times a day, or continued for two or three weeks, the energy of this organ becomes impaired, as manifested by an irregular and fluttering pulse, lowering of the temperature, and general symptoms of collapse. Associated with the latter we sometimes notice loss of consciousness, and the development of the Cheyne-Stokes type of respiration. These symptoms are usually quickly relieved by suspending the administration of the drug and giving stimulants.

The greater part of the article is then devoted to the consideration of special indications, the mode of application, and uses of the drug in scarlatina and diphtheria. Demme concludes his carefully prepared paper as follows:

*First.*—In those cases of scarlatina where the eruption is, from the outset, slow to appear and imperfect, and where there are concomitant symptoms of severe cerebral irritation or depression, such as clonic or tonic convulsions, tetanus, sopor, etc., the indications are best met by the hypodermic injection of a full dose of pilocarpine. This induces an increased afflux of blood to the skin, thereby relieving the overloaded heart and brain, and the profuse diaphoresis which follows also carries off more or less of the specific scarlatinal poison.

*Second.*—Scarlatinous nephritis varies in degree from moderate inflammatory hyperæmia to the most intense glomerular and interstitial inflammation, and may develop at any period in the course of scar-

latina. It cannot be prevented by the early and regular administration of pilocarpine, but when present, the symptoms can frequently be relieved by the employment of this drug—at any rate, more surely and rapidly than by any other agents.

*Third.*—Pilocarpine is not a specific in diphtheria, as claimed by Guttman (*Berliner klinische Wochenschrift*, No. 40, 1880), but it does act favorably by increasing the secretion of the diseased parts, and thus hastening the loosening and exfoliation of the diphtheritic membranes. It has a similar action in catarrhal laryngitis, croup, and bronchitis with deficient secretion, catarrhal pneumonia, etc. It may also promote the expulsion of membranes and mucus by the initial vomiting, which frequently follows its subcutaneous administration.

Demme states that he obtained the purest samples of pilocarpine from Trommsdorff in Erfurt, and Merk in Darmstadt. Finally, it may be remembered that the drug does not act well administered hypodermically to patients with excessive œdema, or in those affected with scleroderma.

Tincture of Convalaria in Paroxysmal Cardiac Palpitation.—Semonowski reports a case of nervous paroxysmal palpitation of the heart, associated with pain radiating into the left arm, occurring in a pale, nervous woman of thirty years. All kinds of remedies had been employed without benefit, until Botkin advised the administration of tr. convallariæ majalis, in ten-drop doses, four times a day. In the course of a week all the subjective symptoms had subsided, while a previously demonstrable moderate dilatation of the right ventricle and of the left auricle diminished so far as to leave only slight dulness on percussion in the upper part of the left parasternal line. —*St. Petersburger medicinische Wochenschrift*, May 7, 1881.

Chromidrosis.—Dr. T. Colcott Fox reported two interesting cases of chromidrosis to the Clinical Society, London (*Lancet*, June 4, 1881), in which a deep blue-black pigment had exuded upon the skin of the circumorbital region. One case occurred in a girl aged eighteen years, whose menses appeared first at the age of fifteen, and had never since been regular; and since that age the girl had suffered from general malaise, severe headache, and habitual constipation. She was not a hysterical subject. The pigmentation was first noticed in September, 1880, on the lower lids, whence it gradually spread over the adjoining portions of the cheeks. It was always less at the catamenial periods, but seemed to bear a direct relation to the very obstinate constipation, and was more intense and extended the longer the interval between the relief of the bowels. It was found on many occasions that whenever the latter became regular the pigmentation disappeared. As a proof of its genuine character, Dr. Fox described the precautions taken to watch the case on one occasion for thirty-six hours, after the face had been thoroughly cleansed, but the pigmentation steadily returned. The urine was examined on several occasions for indican, which was found always to increase markedly in amount *pari passu* with the constipation and the exudation of pigment on the face. This fact, and the relation of the exudation to habitual constipation, are new points in connection with the affection. Examination of the pigment showed it to present characters in all respects similar to those hitherto recorded by Charles Robin and others. The indian-ink-looking amorphous granules were found insoluble in almost all reagents, hot or cold, but displayed a deep blue color when moistened with glycerine, and when dissolved in hot sulphuric acid, at first gave a beautiful purple hue, and finally, a bistre tint. The pigment was evidently indigogenous.

The second case was a girl of eighteen. She was hysterical and phthisical, and suffered also from flatulent distention and constipation. The black, powdery pigment afforded similar reactions to that in the first case, but the pigmentation was slighter and more fitful in appearance. In both cases, any heat, emotion, etc., which determined the blood to the face, increased the pigmentation. Dr. Fox, in consideration of the fact that these were the first cases presented to a London society, with the exception of one shown by Sir Benjamin Brodie in 1845, entered into a short *résumé* of the subject, and, in reply to the many inquiries of the members, said that there was very little, if any, altered sensation in his cases. It was impossible to say whether the pigment was exuded from the sweat or from the subaceous glands, but it contained no oily matter, which was evidence against its being a steatorrhœa, as Nelligan supposed. No constitutional disturbance followed the removal of the pigment, no bacteria were found in the pigment, and the effect of emotion in producing it was very marked. The indican rapidly became oxidized on exposure to air, and if its occurrence in sweat be admitted, there would be no difficulty in explaining the deposition of the pigment.

A Novel Method of Treating Caries.—Dr. Oscar Kollmann, house physician to the prison for women in Würzburg, reports the perfect recovery of four cases of osseous caries under the employment of inunctions of green soap. In the first case the disease affected the sternum and bodies of several vertebræ, the patient being completely bedridden; the second case was one of caries of the small bones of the foot, while the last two patients had caries, respectively (carious ?) periostitis of one or more ribs. The inunctions were made twice a week, with a sponge, along the back of the trunk and thighs as far as the knees, followed after a half-hour with ablution with warm water. The quantity of the agent employed was fifteen grammes—about a tablespoonful. No other treatment was resorted to, except the internal administration of cod-liver oil. Meanwhile the patients received ordinary prison diet, with the exception in the first case of a glass of beer daily. The author cautions against employing the inunctions oftener than twice a week, in order to avoid exciting an artificial eczema, which would require the discontinuance of the applications for a prolonged period.—*Berliner klinische Wochenschrift*, May 9, 1881.

Antipyretic Action of Conchinin.—Freuderberger (*Deutsches Archiv für klin. Med.*, vol. xxvi.) has found conchinin (Van Heyningen's betachinin and Pasteur's chinidin) very similar to quinine as an antipyretic and as a specific for malarial fevers. It may be given in aqueous solution with the addition of ac. sulphuric., q. s., or in wafers. The dose should not exceed three grammes. In typhoid fever two grammes were sufficient to reduce the temperature 2° C. (3.6° Fahr.) and sometimes even 3° C. (5.4° Fahr.) and more, without producing collapse. In disease having a typical fever-curve, two grammes of conchinin were as efficacious in reducing the temperature as ten grammes of salicylate of soda, while its secondary effects were much less disagreeable and violent than those of the latter.—*Allgem. med. Central-Zeitung*, No. 41, 1881.

# THE MEDICAL RECORD:

## A Weekly Journal of Medicine and Surgery

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 6, 1881.

## THE PRESIDENT'S PROGRESS.

PRESIDENT GARFIELD, at the present writing, is doing extremely well, and he seems to have the best prospects of ultimate recovery. To be sure, it cannot be positively said that he is out of danger, or that a relapse similar to the one of two weeks ago may not occur. But the possibility of any complications is growing less every day.

The reported finding of the ball in the abdominal wall, to the right and below the umbilicus, clears up, in a very gratifying manner, some of the grave misgivings as to the extent of injury inflicted and the ultimate chances of recovery. The instrument by which it is claimed that the location of the ball has been found is fully described in another column. If it really has the value asserted for it, the surgical art has received an important addition to its armamentarium.

But, after all, the question of the exact position of the ball is now of secondary importance compared with the precise relations of the ball to the suppurating track.

The best that can happen is the enclosure of the hidden ball in a cyst, and the gradual closing of the wound from the bottom toward the surface. Possibly this has already occurred. There are many things to favor this desirable result in the case. The ball, although more or less flattened, is probably not ragged, as its shallow cup is not capable of sufficient expansion to spread out and serrate its edges. Its extremity is squared off instead of being sharply conical, and it is not therefore more liable to cause irritation than an ordinary rounded or bluntly wedge-shaped bullet. It is, according to latest accounts, quite deeply imbedded in its present locality, a condition most favorable for the encysting process. On the other hand, the missile may be in such a condition, and in such a relation to surrounding parts, as to resist nature's efforts to enclose it in a cyst, and thus be a constant source of irritation and consequent danger. In the absence of positive proof to the contrary as to the ball being such an irritant, its presence in President Garfield's body will be always a natural cause for great anxiety. It is a pertinent question, in view of this fact, whether the time has not come for determining, by some explorative procedure, the real conditions of the surroundings of the ball, and thus clear up all the harassing doubts which must continue to hang around the prognosis. Of course there are many circumstances that have to be taken into account in dealing with individual cases. There is no doubt that such have been duly weighed by the distinguished surgeons in attendance, but in studying this interesting and important case we are privileged to argue on general principles, and make our applications of the same in accordance with the evidence before us.

We have repeatedly taken the ground against probing gunshot-wounds of the abdominal cavity. Consequently, we have heretofore applauded the forbearance of the gentlemen in charge of the President in regard to that point. Now, however, in view of the apparent necessity of clearing up any doubts in regard to the actual state of the entire bullet-track, and the possibility of extracting the missile itself, thus making a complicated case a simple one, it appears warrantable to make a more careful and thorough examination of the wound than has yet been done. The objections against probing a wounded cavity do not longer obtain. Time enough has seemingly elapsed to surround the track of the wound by firm adhesions, thus protecting it from injury of any contiguous organs. If nothing more can be found than the extremity of the cul-de-sac, an important point can be gained in reference to deciding upon the practicability of more direct and, consequently, more effective drainage. If the drainage can be proved to be perfectly satisfactory by actual exploration of the wound, all the difficulties in the case will be cleared up. If the contrary be found to be true, the sooner the necessary outlet is made the better. The danger would appear to be not so much in obtaining a free discharge from the wound of entrance, as in insuring it at all times during the suppurative processes from the deeper portions. The mere extraction of the ball, desirable as this may be, is altogether secondary to the establishment of the most thorough drainage. But these are such self-evident propositions, that we cannot believe they have not been thought over and acted upon by the distinguished surgeons in attendance upon the case. As yet, however, there is no report of the exploration of the sinus farther than was necessary to insure the extraction of the fragment of rib found at the bottom of the pus-pouch.

It is quite true that the case involves an unusual responsibility in its management. There is a nat-

ural and laudable desire to lean toward conservatism, but in an ordinary case, as it occurs in the hospital ward, we do not think that any surgeon would hesitate, at this stage of its progress, to satisfy himself by the necessary explorations not only where the missile was hidden, but whether or no there was any removable obstacle to the rapid healing of the wound. In view of the fact that the President is never safe so long as deep seated suppuration is present, the course and condition of the entire wound-track are matters of much anxiety.

Concerning the general condition of the distinguished patient, there is little to be said that is not favorable. The main indications are at present to insure the freest possible drainage from the wound, and to give the most liberal support to the general system by food and stimulants. These indications fulfilled, there is no reason, barring accidents, why the improvement should not continue and the case should not be brought to a satisfactory conclusion.

We take pleasure in affirming again that the treatment thus far is beyond criticism, and it is fair to suppose that so long as the present medical staff remains in attendance nothing will be left undone to insure the comfort, safety, and ultimate recovery of the illustrious patient.

---

### AN INSTRUMENT FOR MEASURING THE PRODUCTION OF HEAT IN LIVING BODIES.

At a meeting in June last, of the Société de Biologie, of Paris, M. d'Arsonval claimed to have invented an instrument which measures with exactness the amount of heat produced by living beings. It is automatic in its working, and tells the amount of heat generated at any given period of time.

The usefulness of such an instrument, if it really performs with exactness what is claimed for it, will be keenly appreciated by physiologists and pathologists. The clinical thermometer, as is well known, shows but one side of the heat-processes going on in our bodies. Thus, the high temperature that it registers may be due to several different causes, such as heat-retention, increased heat-production, or both. H. C. Wood has shown that the actual heat-production may be less when the temperature, as recorded by the thermometer, is high, as in fever, than it is when the healthy animal is richly fed. Again, there may be a largely increased heat-production while the thermometer registers a low temperature, as when the skin of a rabbit is shaved and varnished. Altogether, it is easy to see that the clinical thermometer gives us but an imperfect idea of the real changes that underlie variations in bodily temperature.

M. d'Arsonval has as yet experimented in but a few directions, but he already announces some novel facts. He has studied the differences that exist between mammals and birds as regards the production and retention of heat. Making the experiments upon dogs and cats, he finds that these animals produce heat at an average rate of between seven and nine calories per hour to every kilogramme of body-weight, the temperature of the surrounding air being at 12° C.

On the other hand, pigeons and fowls generate only between four and one-half to five and one-half calories per hour for each kilogramme of body-weight. The experiments, therefore, seemed to show that birds generate less heat per pound of body-weight than mammals. As the temperature of birds is 9°, or more, higher than that of mammals, the conclusion must be that they are good retainers, but small producers of heat.

Some further experiments tended to confirm the above conclusions. When the mammals were starved for forty-eight hours, no very great decrease in heat-production was noticed. In pigeons and fowls, however, which were starved for the same length of time, the heat-production fell to one-third or one-half the normal. This would indicate perhaps a weakness in the heat-producing power, which accords with the previous experiments.

The above are all the results that have as yet been communicated by M. d'Arsonval. It remains to be seen whether they can be corroborated, and whether his instrument possesses the accuracy which is claimed for it. If it does, a great advance can be made in settling vexed questions in the pathology of fever.

---

### NEW EXPERIMENTS IN PREVENTIVE INOCULATION.

M. Pasteur recently made a communication to the Paris Academy of Medicine which, according to the *Gazette Médicale de Paris*, "makes an epoch in the annals of science." Without admitting such a claim as this, the communication is certainly of interest in connection with previous remarks which we have made upon the subject of preventive inoculations.

When Pasteur discovered a method of so cultivating the specific germs of chicken-cholera as to give them the power of preventing the disease when inoculated, he asserted it to be possible to treat other specific organisms in the same way. This he has recently done for the virus of charbon. He was furnished with an unusually good opportunity of testing the power of his modified virus. The Agricultural Society of Melun put at his disposal sixty sheep, to be experimented with as he chose.

Ten of these were separated from the rest and kept subject to inspection. Twenty-five others were inoculated twice with the cultivated virus of charbon. After a sufficient time these and another twenty-five sheep were inoculated with the pure virus of the disease. The fifty sheep were then allowed to mingle

together in the same inclosure. The twenty-five not "vaccinated" did not take the disease, while the others did. Those of the latter that died were buried in an inclosure together. A certain number of vaccinated and unvaccinated sheep were then turned into this inclosure and allowed to pasture there. The unprotected were soon attacked with the charbon, while the others were not. Thus M. Pasteur claims to have demonstrated not only the protective power of the modified virus, but also a previous assertion, that sheep pasturing upon ground where animals killed with charbon are buried, will catch the disea e.

M. Pasteur made similar experiments with ten animals of the bovine species, and asserts that the same protective power was secured to them.

Pasteur's communication was received with applause by the society, yet it was not allowed to pass without criticism. M. Colin claimed, and with justness, that the same results had been obtained by himself a year ago, and by Toussaint a little later. He might have added that Greenfield and Burdon-Sanderson had also experimented successfully in the same line. Still no one has ever obtained successful results upon so large a scale or with so much uniformity.

It was also suggested that it yet remains to be proved that the preventive power of the inoculations lasts for any considerable length of time.

Whatever be the question of priority, however, it is certain that Pasteur's results have attracted the most attention of any yet made in this line. And they will probably give a fresh impulse to studies in this direction. It must be remembered that the successes in preventive inoculation have, so far, been with diseases having a close pathological resemblance. And before the experiments of Pasteur, their practical application did not seem easy.

---

### OUR INCREASED DEATH-RATE.

Dr. Nagle has published the mortality report of this city for the six months ending June 30, 1881. It shows the number of deaths and the causes of the same during that time. In view of the agitation over our dirty streets last spring, and the strong views promulgated by some medical men on the subject, the statistics published in another column have an especial interest.

It will be seen that the mortality for this year has so far been about twenty per cent. greater than it was during the corresponding period in 1880, the actual excess of deaths being three thousand one hundred and eighty-nine.

This excessive mortality represents an absolute as well as a relative increase. The death-rate per thousand last year in the same period varied, most of the time, between twenty-four and twenty-six. In the past six months it has kept at or above thirty per thousand, and it has been, on the whole, rather higher in the last half of the six months.

The great severity of the past winter was, no doubt, the chief factor in thus raising the death-rate. Examination of the tables, however, shows that the unusual coldness did not act powerfully to increase the mortality from lung diseases. The increase in deaths from pneumonia, bronchitis, and consumption is comparatively small.

On the other hand, the increase in deaths from zymotic diseases is very striking, amounting to about forty per cent. What is still more ominous is the fact that this increase is a continuous one. Last year we called attention to the fact that the mortality from several zymotic diseases, but especially from diphtheria, was almost double that for the year 1879. We now find that the death-rate from this disease has again more than doubled. Scarlet fever, which was not very prevalent in 1880, has increased five-fold in the last half-year. An increase in deaths from typhus, typhoid fever, and small-pox, also swells the list.

The notable feature, therefore, in the statistics, is the evidence it gives of the prevalence of the acute infectious diseases. The severe cold and deep snow, combined with bad drainage and foul streets, are sufficient, in part at least, to explain the increase.

We have just received, as we go to press, the statistics of mortality for the month of July last. They confirm the facts above given regarding an increased death rate. There were 4,378 deaths in this city in July, 1881, while in the same month of last year the number was 3,487. This is a little remarkable, in the light of the fact that a year ago the weather was extremely hot, while the present season has been a cool one.

---

Chaulmoogra-Oil in Leprosy—The Nervous Origin of the Disease.—A case of leprosy is described by Dr. William Alexander (*Lancet*) which was markedly relieved by the use of chaulmoogra-oil, after gurjun-oil and cod-liver oil had been tried to no purpose. The symptoms in the case were redness and tubercularization of the face, with symmetrical pigmentation and anæsthesia of thighs, trunk, and arms. The anæsthesia closely coincided with the pigmentation. The pigmented skin was raised in tubercles over the course of the ulnar nerves, and those nerves were felt standing out like cords.

The same writer reports also a case of symmetrical anæsthesia and pigmentation in another patient. This was not a case of leprosy, but the similarity in symptoms, up to a certain point, seemed to prove that there was a similar lesion in the two diseases. As it has been proved that the central nervous system has some control over pigmentation, this fact, taken in connection with the anæsthesia, points toward a nervous origin for leprosy. Danielsson and Boeck, in 1848, Tschirew, Piffard, and others, have made contributions to this view of the pathology of this disease.

THE HUMAN BODY: an Account of its Structure and Activities, and the Condition of its Healthy Workings. By H. NEWELL MARTIN, M.A., M.B.D.S.C. New York: Henry Holt & Co. 1881.

THE present work is one of a series designed to supply the lack of authoritative books upon different branches of science which shall be intelligible to others than specialists or strictly scientific men. In the present work Dr. Martin has, we think, succeeded admirably in the object which he has attempted. It presents a clear, succinct, and not very technical account of the physiology of the human body, as given by the best and latest authorities. Besides the purely physiological part, which is the most prominent one, we have a great deal of anatomy, especially microscopic, and there is some attention paid to the subject of hygiene. The physiological part of the work is taken, to a large extent, from Foster and Hermann, but the matter is admirably condensed, and is rearranged with additions of the author. The book is not unworthy, in many respects, to be the text-book of a beginner in medical studies, and there are parts, indeed, which the average reader will probably find rather too abstruse. The chief danger to its popularity, indeed, is that it may be thought too technical for the laity, and too popular for the medical or scientific student proper. Still we would recommend it to both classes, as presenting the latest facts of physiological science in an admirably lucid manner.

The author admits that he is obliged to be somewhat dogmatic in order to be brief, but we can find no fault with the judgment which he has passed upon different disputed questions in physiology.

The hygienic part of the work is excellent also, although it is quite brief. It has additional force from the fact that all the hygienic suggestions follow naturally from physiological facts previously given.

The book is well illustrated and well printed, and is in every way creditable to its author and to the university in which he teaches.

A MANUAL OF THE PRACTICE OF MEDICINE. Designed for the Use of Students and the General Practitioner. By HENRY C. MOIR, M.D. New York: Steam Press of the Industrial School, H. O. A. 12mo, p. 455. 1881.

THIS little manual is one of the best condensations of the theory and practice of medicine that has been published. It contains very much more in its pages than ordinary manuals of four times its size. Those who are familiar with the system of hospital "cram-quizzes" in this city will at once recognize that this book is based chiefly on the notes and abstracts that are prepared by the best quiz-masters for their students. Such abstracts differ very much from ordinary condensations. There is in them no attempt at elucidation of a subject, no unnecessary word, and no discussion of theories. We have presented in this manual, in the same way, only the naked facts, carefully classified and arranged, so that they can be committed to memory as readily as possible.

We look over the book with a feeling of pleasure, for it brings back the times when we sat up till the small hours, cramming up on much the same tables and statistics so well presented here.

The book is based upon the standard text-books, especially Niemeyer, Roberts, and Loomis. There is necessarily a certain amount of incompleteness and lack of harmony in the book, some subjects being better treated than others. There are also a few classifications and tables which can hardly be accepted. Indeed, the fault of such a work in any case is, that in presenting facts briefly and by table, it is necessary to make sharper distinctions, to announce things more dogmatically, and to give greater prominence to some symptoms and some phases of a disease than they deserve. The book of itself would certainly be a dangerous one, but it is something that will help the student vastly in cramming, if that can be considered a desideratum. In the back of the book there is a large number of prescriptions which we do not think add much to its value. Many of them are very commonplace. The author, however, seems to think highly of them, claiming that each one has received the endorsement of experienced physicians.

A TEXT-BOOK OF PRACTICAL MEDICINE, WITH PARTICULAR REFERENCE TO PHYSIOLOGY AND PATHOLOGICAL ANATOMY. By DR. FELIX VON NIEMEYER, Prof. of Pathology and Therapeutics, University of Tübingen, etc. Translated from the Eighth German Edition, by special permission of the Author, by GEO. H. HUMPHREYS, M.D., one of the Physicians to Trinity Infirmary, etc., New York, and CHARLES E. HACKLEY, one of the Physicians to New York Hospital. Revised Edition. New York: D. Appleton & Co. 2 vols. 8vo, pp. 861.

THIS new American edition of Niemeyer fully sustains the reputation of previous ones, and may be considered, as to style and matter, superior to any translation that could have been made from the latest German edition. It will be recollected that since the death of Professor Niemeyer, in 1871, his work has been edited by Dr. Eugene Seitz. Although the latter gentleman has made many additions and changes, he has destroyed somewhat the individuality of the original. The American editors have wisely resolved to preserve the style of the author, and adhere, as closely as possible, to his individual views and his particular style. Extra articles have been inserted on chronic alcoholism, morphia-poisoning, paralysis agitans, scleroderma, elephantiasis, progressive pernicious anæmia, and a chapter on yellow fever. The work is well printed as usual.

THE INDEX CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE, U.S.A. Authors and Subjects, Vol. II.—Berlioz—Cholas. Washington, D. C. 4to, pp. 990.

THE second volume is equal in size to the first, and is, of course, arranged on the same general plan. It includes 12,459 authors' titles, representing 4,934 volumes and 9,810 pamphlets, with 11,550 subject titles of separate books and pamphlets, and 37,310 titles of articles and periodicals. It has been compiled under the direction of Surgeon J. S. Billings, and is a monument of industry and a model of accuracy.

PHOTOGRAPHIC ILLUSTRATIONS OF CUTANEOUS SYPHILIS. By GEORGE HENRY FOX, A.M., M.D. New York: E. B. Treat. 4to.

NUMBERS 7, 8, and 9 of this series contain excellent photographic illustrations of syphiloderma tuberculosum, in its ulcerated, squamous, crustaceous, tuberculous, gummatose, and serpiginous varieties.

THE DIET-CURE: An Essay on the Relations of Food and Drink to Health, Disease, and Cure. By T. L. NICHOLS, M.D. New York: M. L. Holbrook & Co., 1881.

THE author of this work says that he has written it in order "to do good and to get good." His different chapters cover the usual subjects treated of under the head of diet and disease. Their contents seem to be for the most part correct, and well put. The book is a sufficiently useful addition to the list of popular works on this same subject.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

### SARCOMA OF THE THIGH.

DR. A. C. POST presented a specimen of sarcoma, which apparently originated in the periosteum of the femur, near its lower extremity. It was removed from a male patient, nineteen years of age, who first became aware of the existence of the tumor a short time before Christmas of 1880. The tumor had grown rapidly, was very painful, and had given rise to emaciation and loss of sleep. There was no enlargement of the glands in the groin. Dr. Post amputated the thigh a short distance below the lesser trochanter, two weeks ago. Although the patient was very feeble at the time of the operation, he rallied well, and the stump healed mainly by first intention. His general condition, since the amputation, had improved very markedly. In dressing the stump, Dr. Markoe's plan of thorough drainage was adopted.

As a singular coincidence, Dr. Post mentioned a similar tumor existing in a man forty years of age, who first noticed its presence early in the present year. The glandular enlargement was very slight. He proposed to operate for its removal on the following day. The disease had been painful from the mechanical stretching of the parts covering it. The pain had been relieved considerably by smearing the parts with belladonna ointment.

Dr. Post remarked that, in the same class of cases, there would probably be greater security in amputating at the hip-joint, rather than below it. There are many cases in which the disease has advanced so high as to preclude any other operation than amputation at the hip-joint, and in such cases that operation should be performed, although it is natural that the disease should return more speedily than if it had made less progress. The reason why there should be more cases of return of the disease after resection than after amputation through the continuity of the bone, is because there are so many cases which do not admit of any operation other than resection.

One of his colleagues had expressed the opinion that the operation was scarcely justifiable, because the disease is so likely to recur; but Dr. Post answered that, if the duration of life would not be increased, the patient's comfort would be greatly increased, and therefore, as a matter of euthanasia, it would be desirable to remove the diseased mass. He believed that amputation would be justifiable even if the glands in the groin were considerably enlarged.

DR. J. C. PETERS referred to a case in which operative interference was refused, and the patient suffered extremely from pain, and died in consequence of a sarcoma developing after-fracture through the lower part of the femur.

DR. JOSEPH W. HOWE suggested division of the larger nerves of the lower extremity, merely for the purpose of relieving the pain; and he also thought that the growth of the tumor would be diminished by such an operation.

DR. POST remarked that the disability of the patient would not be relieved by such an operation, as the lifeless, motionless, heavy mass would remain.

THE PRESIDENT remarked that, according to his observation, periosteal sarcoma returns in the cicatrix, and he cited one case in which the disease reappeared in the cicatrix several times after amputation.

DR. BRIDDON remarked that heterologous growths increase after division of the nerves.

DR. HOWE thought that Dr. Briddon had no authority for such an assertion, as sometimes the nerve-supply is cut off by the pressure produced by the tumor, and in just those cases the growth is usually most rapid.

The PRESIDENT remarked that it had been proved that, after the vascular supply had been cut off, such tumors will grow just as rapidly as before; but he thought that cutting off the nervous supply would diminish the growth of the tumor.

DR. BRIDDON doubted the existence of nerves within these tumors, and also doubted if cutting off the nerve-supply would in any way influence the growth of the tumor. As to the propriety of removing such growths, there was no doubt that they should be removed early. He thought it would be well, in such cases, to make a primary amputation through the continuity of the bone, and subsequently amputate at the hip-joint when the stump had atrophied, as the latter operation would be much less dangerous than when done primarily.

DR. C. S. BULL presented a specimen of

### GLIOSARCOMA, OR SMALL-CELL SARCOMA OF THE RETINA AND CHOROID.

The patient was a child, about three and one-half years, in whom the parents had noticed a yellow reflex from the fundus of the left eye for more than a year. When the patient was first seen by the physician in charge, there was intense intra-ocular inflammation, very shallow anterior chamber, the lens and iris pushed forward toward the cornea, the exophthalmus quite marked, and a distinct orbital growth. The eyeball and contents of the orbit were at once removed, and the orbit cleaned so far as was practicable; but within a month the growth returned in the orbit and grew very rapidly. The physician very justly did not deem any further operative interference advisable. The child lingered for several months, and then died, apparently from asthenia, with no head-symptoms till toward the end of life.

A microscopical examination showed that nearly all the tissues of the eye were involved, the main growth being a dense infiltration of small, round cells, with some fibrous matrix, not specially marked. It was not possible to say definitely where the growth began, but from indications in some of the sections, it was probable that the growth was at first retinal, beginning in the outer granule layer, and thence extending in all directions. This was also rendered probable by the age of the patient, choroidal tumors

being very rare indeed in young children, while retinal tumors are not very infrequent.

PACHYMENINGITIS HEMORRHAGICA.

Dr. George L. Peabody presented the dura mater removed from the body of a woman, forty-seven years old, who died comatose after an illness of two weeks. The history was incomplete. She was found unconscious on a doorstep, continued unconscious for several days, and then became conscious sufficiently to be able to answer certain questions by movements of her head, and to say yes and no. She was hemiplegic, the paralysis being entirely upon the right side of the body. She died completely comatose. At autopsy he found pachymeningitis hemorrhagica, not confined to, but most marked upon the left side of the head. A very copious hemorrhage had occurred. There was fluid blood which was undergoing retrograde metamorphosis, and deposit of pigment had begun in the tissues. The entire left hemisphere had so changed in shape as to make it nearly unrecognizable as a central mass. Fluid blood had accumulated upon the surface of the brain to the extent of *six* ounces, the hemorrhage occurring apparently into a portion of the false membrane, or else between the tissues of the dura mater; for it had filled all the available space, and had evidently burst through the false membrane and made its way into the space between the dura mater and the pia mater. The patient also had chronic diffuse nephritis.

THE VAPOR OF WICKERSHEIMER'S FLUID FOR PRESERVING SPECIMENS.

Dr. Peabody presented a specimen of gangrene of the foot and lower part of the leg, which had been mounted in the vapor of Wickersheimer's fluid under a bell-glass for one month, and was in a perfect state of preservation. He also presented two hands mounted in the same manner, removed from the body of a negro, each of which had a supernumerary finger. The man died of phthisis, at the age of thirty-two. His father and grandfather had supernumerary fingers, and also toes.

VESICAL, RENAL, AND BILIARY CALCULI.

Dr. E. C. Wendt presented a vesical calculus removed at autopsy, which had a portion of a soft catheter for a nucleus. The man had suffered from vesical catarrh for a number of years, had been accustomed to use a catheter, and finally the soft instrument broke, and a portion of it was left in the bladder. From that time his vesical symptoms were much aggravated, and at times there was a bloody discharge. The man died of pneumonia.

He next presented an almost perfect cast of the renal pelvis. The patient had suffered from repeated attacks of renal colic.

Dr. Wendt also presented numerous specimens of biliary calculi, and in each instance hepatic symptoms had been absent. In this connection he made the suggestion that the gall-bladder may not be absolutely essential to the human economy. Gall-bladders distended with biliary calculi are found very frequently at autopsy, and it is impossible for bile to enter them when so filled.

Dr. Post asked if there was any special reason why the foreign body was not removed from the man's bladder?

Dr. Wendt replied, "the patient's general condition was so poor that it was believed an operation would be inexpedient."

Dr. Briddon remarked that he had presented to the society, some time previously, two vesical calculi in which the nucleus was a portion of an elastic catheter. In one case the fragment of the soft instrument remained within the bladder only a short time, but became so encrusted that it could not be removed through the urethra, and perineal section was made.

Dr. Post remarked, concerning removal of foreign bodies and calculi from the bladder under unfavorable circumstances, that a paper had been written by a Scotch surgeon, who had shown that by operating upon unfavorable cases he had obtained a favorable degree of success; and the opinion also was given that surgeons had been too much in the habit of regarding unfavorable cases of foreign bodies and stone in the bladder as beyond the reasonable reach of surgical aid. He thought there was no condition in which the patient was likely to survive an operation in which he was not likely to derive benefit from it, and therefore it was desirable that such foreign bodies should be removed.

The society then went into executive session.

## NEW YORK SURGICAL SOCIETY.

*Stated Meeting, April* 26, 1881.

Dr. H. B. Sands, President, in the Chair.

Dr. E. L. Keyes read a paper on

ARTERIO-VENOUS ANEURISM.

Dr. J. C. Hutchison, in 1864, in a military hospital in Newark, saw a case which was the result of a wound of the femoral vein and artery, inflicted nine years before with a penknife. The patient had suffered no inconvenience from it, and no marked tumor had developed until about the time he was operated upon. It was at first supposed to be a traumatic aneurism of the femoral artery pressing on the femoral vein, and for its relief the external iliac artery was ligated without benefit. Six months subsequently a surgeon applied a ligature to the common iliac artery, and the patient died of peritonitis a week after the operation. The surgeon cut directly through the peritoneum, because he found it impossible to reach the artery in any other manner. Dr. Hutchison thought that a ligature above and below the tumor might have cured the patient.

Dr. Van Buren referred to the case of an American from St. Louis, reported by a London surgeon, in which the patient was wounded by the accidental discharge of a Derringer, the bullet passing into the front of the thigh, wounding the artery and the vein, and an arterio-venous aneurism finally resulted, which led to a great deal of diffuse swelling and weakness of the limb, and also more or less disease of the skin. The patient applied for relief on account of the general eczema of the limb with ulcers. Apparently the mixture of the arterial and venous blood kept up the cutaneous disease. The case was reported at one of the London societies; several prominent surgeons were consulted, and all declined to interfere by operation. After one or two years it was decided that the patient should wear a laced stocking, which relieved him to a very great extent. It had always seemed to Dr. Van Buren that the case conveyed a practical lesson of a great deal of value, for experience has taught us the uncertainty of all means heretofore applied for the cure of this condition, and it has also taught us that the incon-

venience which follows the malady is really not sufficiently great to warrant an operation, which places the patient in danger. He believed that the London surgeons did right concerning the man from St. Louis.

The recent success by Annandale rather revived the feeling that it would be proper to undertake an operation with the view of effecting a radical cure, and that was the consideration which influenced him in advising operative interference in Dr. Keyes' case. But, after the additional experience which it had given, he would advise *against* any operation whatever, for this man's condition really was not a serious one.

There is no real danger to be apprehended from letting them alone, other than using such treatment as is commonly adopted for varicose ulcers; and probably the most serviceable is properly graduated pressure, for example, by means of Martin's bandage.

Dr. Keyes said that in Mr. Cox's case the aneurism burst.

Dr. Van Buren further remarked that Nélaton directed attention to the fact that the bruit is unequal in the direct and return current; that there is a bruit with the contraction of the ventricle, and a second bruit with the return current, which he regarded as pathognomonic of this form of aneurism. That statement was valid in two cases which Dr. Van Buren then had in mind.

The President asked how the second bruit was explained, and Dr. Van Buren said that it was due to the crossing of the currents of blood. In Dr. Moth's case the gangrene which followed was quite evidently due to the fact that the blood was always of a mixed character, and did not furnish the requisite amount of nutrition.

Dr. Keyes ascribed the absence of gangrene in his case to the peculiar character of the aneurism.

Dr. L. A. Stimson was inclined to believe that gangrene following the Hunterian operation is not due so much to the mixed character of the blood as to the mechanical condition, which is similar to that which exists when two aneurisms exist in the course of a vessel, or when a second ligature has been applied higher up in the course of the vessel. In that case two collateral circulations are required to maintain the nutrition of the limb, and in a case of arterio-venous aneurism in which the ligature is applied high up, the blood which makes its way around does not pass over the limb to be distributed to the distal portions, but enters the venous current and returns to the heart. In other words, the pre-existing condition remains, with the addition of a decrease in the supply of blood for the limb below. If that be so, the principle which governs the treatment of traumatic hemorrhage would seem to require the application of a ligature close to the sac, and then the only danger would be from a recurring strain through the distal segment of the artery. Whether that would be sufficient to continue the disability he was not able to say, but thought it would not.

Dr. Keyes said that that operation had been performed by Anel, and in all of his cases it failed. A single ligation of the artery above the sac is quite likely to result either in secondary hemorrhage or gangrene.

Dr T. M. Markoe had always regarded the condition of a limb which was the seat of arterio-venous communication as one in which vitality was diminished by reason of a mixture of arterial and venous blood. If that be true, cutting off all direct supply of blood, as in the Hunterian operation, leaves the opportunity for intermixture of the two kinds of blood without the benefit which is derived from the force of the direct current of arterial blood. With that view, it had always seemed to him that the condemnation which the operation had received from the profession was a just one. All these dangers from intermixture might be entirely avoided by ligating the artery both above and below the injured point, thus leaving the parts in very much the state of a simple varicosity of the veins opposite the point of communication. In cases of mere arterio-venous communication, he was disposed to let the limb alone; but when an artery had communicated with a vein so as to produce a tumor between the vessels, or to make a tumor on the vein, he thought a condition existed which justified the consideration of an operation, and he would be disposed in those cases to ligate the artery above and below.

Dr. Keyes thought that Bryant recommended such a procedure, but that Spence's case was the only one which he had found recorded.

Dr. Van Buren remarked that the alteration which exists in the veins in this form of disease is so constant, that when we attempted to tie the artery above and below, it would be difficult to distinguish between arteries and veins, and the operation would finally not differ very greatly from that of Antyllus.

The President thought that it would be difficult to adopt the plan proposed by Dr. Markoe, as the operation might not be practicable. The topography of the parts is often so much changed by the disease, that it would be impossible to secure the artery above, and especially below, without opening the sac or cutting through veins, which pulsate as do the arteries and carry the same kind of blood. Dr. Sands then referred to a case which came under his care in Roosevelt Hospital, in 1875, on account of an arterio-venous aneurism of the right leg. Although the leg was considerably enlarged, there was no circumscribed tumor, but arterio-venous communication was evident, and a loud murmur was heard over the site of the original wound, which was made with a penknife. It was supposed to have implicated the peroneal artery and vein. Pulsation extended over nearly the entire length of the leg, and the superficial veins of the leg and foot were distended, and pulsated with the same force as the arteries. The murmur was systolic, and besides this there was a rough sound which was continuous. The patient had, in addition, some eczema, and an ulcer on the leg of the size of a silver half-dollar, which it was feared would open some vessel, and thus give rise to serious hemorrhage. That was the main reason why the patient sought medical advice. Rest, position, and the application of a bandage to the limb, caused the ulcer to heal. Afterward he wore an elastic stocking, and since then he had from time to time reported himself to Dr. Sands as being very comfortable. A similar case also came into Bellevue Hospital, and was under the President's observation, and in that instance also all the surgeons were averse to operative interference. He had never seen an arterio-venous aneurism which was so threatening in character as to render an operation expedient.

Dr. Markoe said that most of these tumors have communication from the side of an artery into the side of a vein. Dr. Keyes' case presented a remarkable exception in that the artery opened into the dilated vein and was not continuous from above downward, which is the usual condition. He thought

it would not be difficult to follow a continuous vessel either from above downward or from below upward, and operate by ligating the vessel above and below.

THE PRESIDENT asked if it would be practicable to do so when the arterial passages were overlaid by the tumor?

DR. MARKOE thought that such an overlapping might embarrass, but not forbid, the operation. He thought it was the only reasonable operation, if any was to be performed.

THE PRESIDENT said, that in certain cases of arterio-venous aneurism, the Hunterian operation, if it does not always cure, rarely does any harm.

It is well known that most of the cases of orbital aneurism are cases of arterio-venous communication between the internal carotid artery and the cavernous sinus. Some of these cases have been cured by ligating one or both carotid arteries in succession, while many have not been affected by such operations; but only a very few patients have been injured by it. The ligature in his hands had been serviceable in two cases within the last eighteen months, diminishing the protrusion of the eyeball and the buzzing noise; but in neither case did it cure, and in neither case would ligation of the opposite carotid artery have effected a cure, because it was ascertained that pressure made so thoroughly upon the artery as to arrest all circulation through it did not cause the murmur to disappear; for that reason he did not ligate that vessel.

DR. MARKOE remarked that it had been done successfully several times. Further, in aneurism in the cranium, the lesion is within the cavernous sinus, which has strong walls, is on the artery itself, and is generally due to traumatism. There is a communication with a cavity which has non-yielding walls.

DR. BRIDDON referred to a case in which he ligated the carotid artery for a pulsating tumor of the orbit. The patient died twelve days afterward from causes not well ascertained, but the exophthalmos had greatly subsided before death occurred.

### OSTEOCHONDROMA OF THE FEMALE BREAST.

DR. LANGE presented a specimen with the following history:

A woman, widow, fifty-one years of age, from a healthy family, noticed a small nodule about the size of a berry in her left breast, below and laterally of the nipple, something like twenty years ago. About seven years ago the same was about the size of a nutmeg, and since her climacteric period, about three years ago, it has grown distinctly, without, however, causing any discomfort. A yellowish fluid here and there was discharged from the nipple, which ceased to flow about five months ago, and since then the growth became rapid, and a troublesome, burning pain set in. About the time of the operation, the greater part of the breast consisted of a hard mass, in which one large and several smaller nodules could be distinguished. Two weeks previous a cystic cavity had been opened by incision, containing fluid of the same quality as that discharged from the nipple before. Several axillary glands were slightly increased in size. The operation consisted in entire removal of the breast, together with the contents of the axilla, in one piece. Speedy recovery took place under the permanent antiseptic dressing.

The tumor—its greater part—consisted of true cartilaginous and osseous tissue, the former mostly in its variety as hyaline cartilage. One large, roundish division, about one and one-half inch in diameter, contained a large, bony nucleus. Otherwise the tumor consisted of a number of smaller roundish divisions, separated from each other by strong layers of fibrous tissue, and showing partly glandular structure with cartilaginous nuclei scattered.

The case seems to be the first of this variety observed, beyond doubt. Billroth, as well as Gross, in their very exhaustive treatises on tumors of the mammary gland, doubt its occurrence altogether, and do not regard the few cases heretofore described as such by Astley Cooper and Cruveilhier, as stated beyond doubt.

### HERNIA INGUINALIS PROPERITONEALIS INCARCERATA GANGRÆNOSA—RESECTIO INTESTINI—MORS.

Mr. W——, forty-five years of age, an otherwise healthy man, had noticed a right inguinal hernia about one year and a half. He always wore a truss, which gave him entire relief, and proved to be sufficient for keeping back the intestine.

On April 6th he was taken, without apparent cause, with nausea and vomiting. He had a passage on the evening of that day, but none after that. The following two days vomiting became very vehement, the abdomen somewhat tympanitic, and the patient commenced to feel weak. The physician, who saw the patient on the second day, administered narcotics, and on the fourth day vomiting subsided, but repeated ructus and nausea remained.

The case was considered to be one of internal incarceration. At no time had anything of the hernia been visible, nor had manipulations been made by the physician or the patient himself. A certain tenderness of the abdomen, and especially so in the right hypogastric region, had existed since the patient was subjected to medical treatment.

Dr. Lange was called in consultation on the 10th of April, and found the patient somewhat exhausted and in a state of anxiety; voice weak and slightly hoarse; very slight elevation of temperature, if any; pulse a little accelerated, tolerably strong; abdomen tympanitic, tender spot above Poupart's ligament on the right side, where, on deeper pressure, a resistant, roundish mass could be felt, its location being about the internal opening of the inguinal canal. There existed no protrusion of the abdominal wall whatever above it. Inguinal canal empty.

There was no doubt about the existence of an obstruction of the intestine, and the probability of its being seated above the right Poupart's ligament. He therefore proposed to make laparotomy corresponding to that spot, to ascertain the nature of the obstruction, and then to do whatever might seem advisable. The patient, being afraid of a cutting operation, declined, and asked him to call again at noon, that is, about four hours later. An ample injection of lukewarm water was administered, and morphine by the mouth. At noon the patient felt easier. He had no vomiting, but repeated eructations; had two watery passages, in which small, hard pieces of fecal matter were found, and said that wind had passed. Abdomen decidedly less tympanitic, pulse rather better, expression of face more quiet. The resistant mass above Poupart's ligament could now be felt more distinctly. It was tender on pressure as before, and presented the apparent size of a hen's egg. Dr. L. expressed distrust in this seeming improvement, and advised immediate operation, in case of repeated vomiting. The latter set in a few hours later, but Dr. Lange was not called, and I saw the patient about nine o'clock in the even-

ing, when all the symptoms and a more advanced collapse had made their reappearance. Laparotomy was at once performed above the suspicious spot, and after opening the peritoneal cavity, two pads of small intestine were traced to a small incarcerating opening in the peritoneum, in the direction of the internal opening of the inguinal canal. A roundish mass slightly protruded the parietal peritoneum toward the abdominal cavity, and it was also noticed that quite a slight elevation had marked itself, after the patient was under the influence of the anæsthetic, on the anterior aspect of the abdominal wall.

A very cautious traction was made on what seemed to be the upper part of the incarcerated gut, but without result. It therefore seemed advisable to cut down to the incarcerating ring. For that purpose Poupart's ligament had to be cut across, when the hernial sac, being about the size of a small hen's egg, emerged. So far everything went on satisfactorily, but now, in the attempt to keep back the intestine from protruding through the abdominal opening, while the patient vomited, the contents of the gut at once discharged into the peritoneal cavity. The incarcerating ring was separated as rapidly as possible. A gangrenous hernia, involving the whole thickness of the small intestine, was pulled forward, whose walls, corresponding to incarceration, presented gangrenous defects, the closure having been effected by peritoneal adhesions only. There existed peritonitis, as it seemed, exclusively along the upper largely distended end of the gut, which here and there was covered with yellowish, fibrinous exudations. A great quantity of thin, fecal matter was discharged, and resection of the gangrenous intestine was performed according to the method of several German surgeons. The gut removed in this manner measured about five to six inches on the convex border. The edges of the intestine were united by a double row of Lembert's sutures, for which disinfected silk was used. A stream of warm water was constantly directed through the lower part of the peritoneal cavity, in order to remove as much as possible of the contents of the gut which had escaped into it, and to counteract the loss of warmth, it being imposible to keep back the tympanites and distended gut in a desirable manner. During the operation the upper part of the gut swelled enormously before the provisory ligature, and was punctured once to relieve it from its contents. The little wound thus made was likewise closed by suture. No antiseptic precautions, except spray, were used. The whole operation lasted more than two hours, and the patient became more collapsed and died six hours later. Post-mortem was refused from ritual scruples.

The case belongs to the group of those lately described by Kroenlein as hernia inguinalis properitonealis.

Dr. Lange remarked that further consideration had led him to believe that, taking into account the advanced gangrenous destruction of the incarcerated gut, every task to separate the incarcerating ring must inevitably be followed by breaking of the tender adhesions which closed the gangrenous holes, and that the immediate neighborhood of the latter to the peritoneal cavity must have been followed by escape of fecal matter into the peritoneum. The only chance for the patient, if there existed one, was in opening the sac without disturbing the incarceration, and in establishing an artificial opening above the incarceration.

The latter, as well as the anus præternaturalis, remaining after entire separation of the incarcerated gut, would have to be subjected to operative interference later. Resection of the gut, if carefully performed, is an operation of long duration, which could not be borne by the patient in his state of advanced debility.

Further, it was important to decide what was the cause of the peritonitis already in existence, whether the latter was due to infection from the gangrenous inflammation at the spot of incarceration, or to the hyperdistention of the gut above, which perhaps could involve alterations of the walls, and their diffusibility, giving in this way issue to a peritonitic inflammation. At all events, it was striking that peritonitis seemed to have seized the upper end of the intestine, while the lower seemed to be free from inflammation. On the other hand, cases were not so very rare in which inflammation of the incarcerated gut passed through all its stages without proceeding toward the peritoneal cavity.

Regarding the surgical interference, it will always depend upon the patient's general condition whether we at once ought to resort to resection of the gut, and thus offer the chance of recovery without the very troublesome stage of anus præternaturalis. Individualization in these cases might be particularly important.

An advanced state of debility being present, it might in general be preferable to choose an operation which could be performed in as short a time as possible.

## Correspondence.

### THE TRADE-MARK SYSTEM.

To the Editor of The Medical Record.

Dear Sir—The letter of "Franciscum," in your issue of July 23d, is polite and courteous, but not convincing. The original resolution is so ambiguous and so faulty in syntax that its real intent is masked. Apparently it is framed in the interest of trade, dictatorially assuming to force the physician into the observance of certain rules to be prescribed by pharmacy. Objectionable and entirely beyond the pale of legitimate medicine though it be, the resolution becomes the more obnoxious when used as a species of grotesque advertising. It is here that its real animus shows distinctively. This is seen in the action of the Medico-Legal Society of Philadelphia, wherein it is asserted that there are only two legitimate manufacturing pharmacists in the United States, and that the products of laboratories other than those of these two mentioned must be placed upon an "index expurgatorius." The circular sent out broadcast, professing to be solely in the interest of scientific medicine, winds up as a glaring, presumptuous advertisement, and must, *ex necessitate rei*, defeat the very object which it seeks to gain.

The resolution offered at Richmond lacks every element of strength, of logic, or of legal soundness, and its weakness is most painfully apparent when it has to be bolstered up by devices equally weak.

Should we look at it simply as an emanation of trade rivalry, then we must admit that the system of trade-marks is of great commercial value. Mr. Edmund Johnson, F.S.S., of London, says, in a re-

cent article (*Chemist and Druggist*, May 14th): "The manufacturer, by the registration of a trade-mark, can secure to himself, his successor, and assigns, the absolute and exclusive right to use that mark in connection with his goods, and to identify any particular class of them sold with that mark as being of an unvarying and standard degree of excellence. The public, on the other hand, learn to look upon the manufacturer's trade-mark as a guarantee of such standard degree, from which they know he cannot depart, except under penalty of losing both credit and custom. Thus, the trade-mark affords security to the purchaser, and makes honesty the best policy on the part of the manufacturer."

All medicinal, pharmaceutical, and hygienic trade-marks, or patents, are required by law to be registered. Any one can for himself find out the nature of any trade-mark preparation, since the ingredients entering into its composition are registered and published. Every physician is daily in the habit of prescribing certain preparations of cod-liver oil, of the hypophosphites, of malt, etc., all of which bear trade-marks—and this he does without infringing upon any ethical law whatever. Secret remedies, unpatented, in which no clue to working formulæ is given, are, of course, contraband, and are not prescribed by the enlightened practitioner. The argument is singularly weak which would foist dishonesty upon pharmacists using trade-marks. The active physician can never certainly declare that his prescriptions are always compounded *secundem arte*. The abolition of trade-marks would not secure to him any greater certainty that his prescriptions would be filled with pure, fresh ingredients. He must trust somewhat to the honor of his druggist. If such an one has for years proven himself reliable, the physician may naturally suppose that he will continue so to be. If a trade-mark preparation has for years given satisfaction and accomplished the ends claimed for it, we may also suppose that the best interests of the manufacturer will be subserved by keeping it up to its high standard. The prevention of competition *does not* increase price. Some of the articles without trade-marks are sold at prices which, when relative doses are considered, would send opium up to $150 per pound. Including freight from Jamaica, the price to the importer on one of these drugs is thirteen cents per pound, and it is sold for three dollars per pound. And with this enormous profit, what assurance have we that the drug is pure and genuine? Only the *ipse dixit* of the importer. So much for the resolution as a trade device. How does it concern us professionally? The profession is regarded as an enlightened body, and will not fancy any infringement upon its prerogative. Its members are in the habit of conscientiously discriminating in the use of their remedies, and they do not solicit or require any advice from those outside of medicine upon matters of ethics or of therapeutics. If a medicine is inoperative, they cease using it. If a preparation has lost its efficacy because it bears a trade-mark, they will not prescribe it. If the pharmacists quarrel among themselves, or if they are divided in opinion upon matters of trade, they will consult lawyers and not physicians. In matters of praxis the physician will not feel disposed to yield his judgment to the demands of trade. The whole matter belongs to the manufacturing pharmacists alone, and should not have any place in the discussions of the American Medical Association.

HORATIO R. BIGELOW, M.D.

1502 FOURTEENTH STREET, WASHINGTON, D. C.

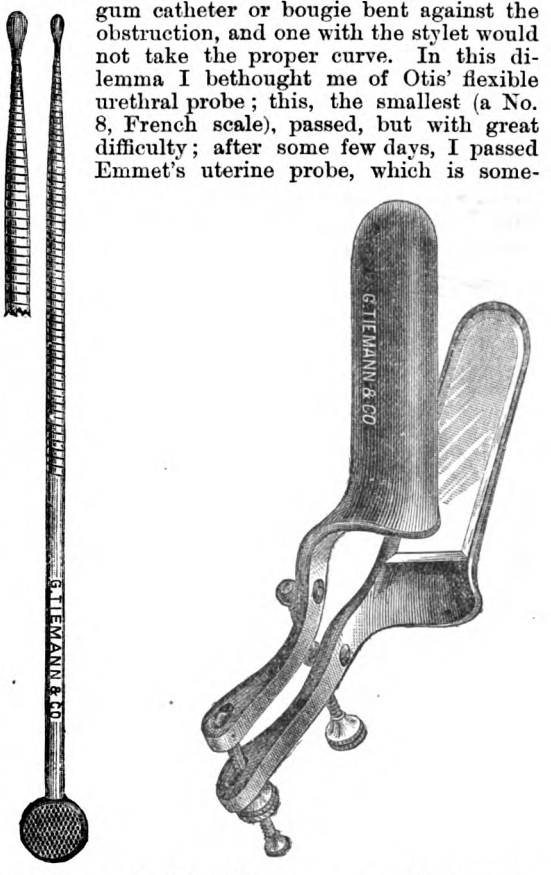
# New Instruments.

## DESCRIPTION OF A NEW DILATOR FOR STRICTURE OF THE ŒSOPHAGUS, AND OF A NEW SPECULUM VAGINÆ.

BY I. L. CRAWCOUR, M.D., M.R.C.S., ENG.,

FORMERLY PROFESSOR OF MEDICINE, NEW ORLEANS SCHOOL OF MEDICINE.

SOME time ago I was called to a case of stricture of the œsophagus. A child, eight years of age, had accidentally swallowed some condensed lye. Four months had elapsed since the accident, and nothing had been done. When I saw the child it had not been able to swallow anything for three days. The smallest œsophageal sound would not pass, a small gum catheter or bougie bent against the obstruction, and one with the stylet would not take the proper curve. In this dilemma I bethought me of Otis' flexible urethral probe; this, the smallest (a No. 8, French scale), passed, but with great difficulty; after some few days, I passed Emmet's uterine probe, which is somewhat larger, and in this way was enabled gradually to dilate the stricture. The child meanwhile was fed by enemata. The stricture was gradually dilated by means of ivory bulbs attached to a flat metallic wire. It struck me that a series of flexible bougies, made on the spiral wire system, would be useful, not only in such cases, but also as urethral dilators, and I asked Messrs. Tiemann & Co. if they could make me some. It was a question whether they could be made of sufficient size and yet retain their elasticity. Messrs. Tiemann have made me a set of four, which are admirable and answer every purpose.



As will be seen by the cut, they are fifteen inches long, and have a broad, flat handle. They terminate in an acorn-shaped bulb and are as follows:

No. 1. Bulb No. 15, French gauge, attached to a short and narrow neck, rapidly increasing to No. 17.

No. 2. Bulb 17, shank 19.

No. 3. Bulb 19, shank 21.

No. 4. Bulb 21, shank 24.

These are the sizes which I think will be found in practice most useful, and, thanks to the skill and patience of Messrs. Tiemann, they are perfectly flexible.

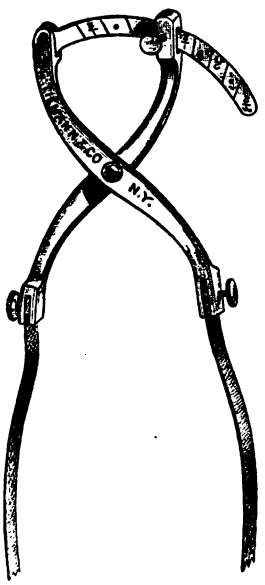
Messrs. Tiemann have also made, at my suggestion, a new speculum. In using nitrate of silver, iodine, or nitric acid, we are very apt to injure our ordinary metallic speculums. To avoid this I suggested hard rubber as the material, and proposed the valves should be lined with mirror-glass, in order to get sufficient light. This also has been done, and I find the instrument works most admirably, and I think supplies a want which has been long felt.

## A NEW CYRTOMETER.

By THEO. A. WEED, M.D., L.R.C.P., London,

CLEVELAND, O.

The accompanying cut represents a cyrtometer, made for me by Messrs. Tiemann & Co., of New York, which I have used for the past five months with very much satisfaction, and knowing it to meet the many requirements not fulfilled by others, I cannot but feel certain that it will be appreciated by all those who employ it.



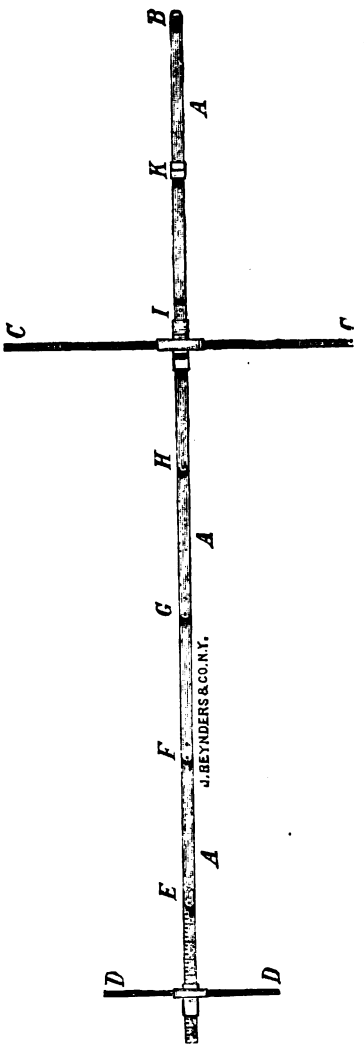
The instrument consists of two arms, each 2½ inches long, joined together by a screw, after the scissors pattern, holding narrow strips of aluminium long enough to completely encircle the chest. To the distal ends of the arms is attached an indicator, which may be set at any point on the scale. The manner of using the instrument is as follows: set the indicator at any given point, by means of the thumb-screw; place the strips tightly around the chest, and mould them to fit exactly the various depressions and elevations; loosen the thumb-screw on the indicator; open the scissor-arms, and remove the instrument without displacing the strips; place the indicator in its former position, and lay the instrument on a large sheet of paper; trace carefully all the curves of the strips with a lead-pencil, and the result will be an accurate outline of the chest-wall. Now, if the instrument be reversed, end for end, upon the paper, the position and character of the difference between the two sides of the chest will become apparent. It is unnecessary for me to discuss the many different diseases of the lungs in which a knowledge of existing elevations or depressions of a localized part of the chest-wall is of paramount importance to the physician.

This instrument, with shorter strips, will be found very useful in many of the local deformities which are found in the practice of every physician, and I am sure that all those who may use it will appreciate its worth.

## AN INSTRUMENT FOR MEASURING THE LOWER EXTREMITIES CORRECTLY.

This instrument was constructed in the early part of 1875, but a description of it has not heretofore been published; being called for by the profession, it is described as follows:

*A, A, A* is a bar of spring steel nine-sixteenths of an inch wide, one-twelfth of an inch in thickness, and five feet six inches in length, at the end and under surface of which, *B*, is fixed an olive-shaped ivory point. *C, C* is a piece of spring steel, one foot and ten inches in length, three-eighths of an inch wide, and one-twelfth of an inch in thickness; this, by means of a slide, into which it is fixed, is made to move upon the bar *A, A, A* at right angles to it. *D, D* is another piece of spring steel, eleven and one-half inches in length, one-fourth of an inch wide, and one-twelfth of an inch in thickness; this also is fixed in a slide, and moves upon the bar at right angles to it.



The subject whose extremities are to be measured with this device, is placed in the horizontal position on the back, the ivory olive-shaped point is placed in the intraclavicular notch, or angle formed by the ascent of each sterno-cleido mastoideus muscle from its sternal origin, and allowing the bar to pass downward over the symphysis pubis, between the lower extremities to beyond the feet; the pelvis is then set at right angles by setting the superior spinous process of each ileum to the edge of the sliding cross-bar *C, C*; then move the cross-bar *D, D* up to the soles of the feet, and if there is any dif-

ference in the length of either extremity, it will be manifest.

The instrument has lock-joints at *E, F, G, H, I,* and the lengths slide upon each other at *K*, so that it can be folded into a space of eleven inches. The cross-bar *D, D* can be withdrawn, and placed in its slide so as to be parallel with the long bar, and the cross-bar *C, C,* being in two sections, can be changed as in the case of *D, D,* making it take up so little space that it can, without inconvenience, be put in the breast-pocket.

For measuring the extremities of persons of diminutive stature, it can be shortened by folding one or more joints, and using the clamps, which are a part of the instrument, to retain the folded part in line. Its weight, when closed, is less than eleven ounces, and it can be obtained from John Reynders & Co., surgical instrument makers, No. 303 Fourth Avenue, New York.

THOMAS H. HOLGATE, M.D.

149 WEST FOURTEENTH STREET, NEW YORK.

## PATELLA HOOKS.

BY JOHN M. WHITE, M.D.,

PLEASANT RIDGE, ALA.

THE accompanying sketch is a modification of Prof. Levis' Patella Hooks.

Two nickel-plated hooks, and a little, hollow rubber cord, are all that are needed to make the instrument. The blunt ends of the two hooks are slipped into the hollow ends of the rubber cord and tied securely with a thread, and this completes the instrument. The rubber cord, instead of Levis' screw arrangement, is much more convenient, besides being more simple,

cheaper, and easier applied. The instrument will adjust itself—will gently and constantly draw and keep the fragments together. (The rubber cord can be made long or short to suit any case.) In its application, the instrument being shorter than the patella, the cord is stretched and the hooks inserted over the fragments; the contraction of the cord then draws and keeps the fragments constantly together. A *set* is required to treat a case of fractured patella, if one will not answer. "They will answer, also, in cases where you do not wish to fasten them into the bony structure, but hook them into two layers of adhesive plaster placed upon the upper and lower fragments, where union had nearly taken place." The set Messrs. Tiemann & Co. sent me were beautifully made, with the proper curve, so they will hold when applied. Rubber pressure, too, may have some advantages.

AN ICE-COOLER on a small scale, but one likely to be very useful in the sick-room, is described by Dr. Rand (*College and Clinical Record*). It consists simply of a cylindrical case of thick paste-board, large enough to hold the tumbler loosely, over which slips an outer closed cylinder, with a button on top. Besides the badly conducting paste-board, there are two strata of included air, which are non-conducting.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending July 23, 1881.

| Week Ending | Typhus Fever. | Typhoid Fever. | Scarlet Fever. | Cerebro spinal Meningitis. | Measles. | Diphtheria. | Small-pox. | Yellow Fever. |
|---|---|---|---|---|---|---|---|---|
| July 16, 1881. | 24 | 12 | 108 | 9 | 44 | 104 | 16 | 0 |
| July 23, 1881. | 19 | 24 | 108 | 8 | 32 | 91 | 26 | 0 |

THE JAPANESE MEDICAL JOURNAL.—We have received from the editor the initial number of the *Jdzo-Shin Bun*, a Japanese Medical Journal, published fortnightly in Tokio, Japan. This is the first of its kind that has been published in the empire, and as far as we can understand from a necessarily casual review of its pages, it contains some "valuable contributions to the science of medicine, and should be in the hands of every working practitioner". who can read the language in which it is written.

SIX MONTHS' DEATHS IN NEW YORK CITY.—The following table shows the actual mortality during the six months ending June 30, 1881, compared with the first six months of 1880, and the number of deaths from the principal diseases:

| | 1881. | 1880. |
|---|---|---|
| Total from all causes | 18,635 | 15,446 |
| Total under one year | 3,873 | 4,177 |
| Under two years | 5,530 | 5,641 |
| Under five years | 7,870 | 6,955 |
| Over seventy years | 1,152 | 1,025 |
| Zymotic diseases | 5,566 | 3,993 |
| Constitutional diseases | 3,936 | 3,447 |
| Local diseases | 7,475 | 6,649 |
| Developmental diseases | 1,085 | 981 |
| Deaths by violence | 586 | 676 |
| Small-pox | 291 | 2 |
| Measles | 268 | 425 |
| Scarlet fever | 1,022 | 206 |
| Diphtheria | 1,114 | 432 |
| Croup | 588 | 387 |
| Whooping-cough | 99 | 150 |
| Typhus fever | 111 | 1 |
| Typhoid fever | 141 | 86 |
| Malarial fever | 266 | 191 |
| Erysipelas | 138 | 129 |
| Diarrhœal diseases | 749 | 1,477 |
| Alcoholism | 114 | 106 |
| Rheumatism and gout | 140 | 112 |
| Cancer | 362 | 338 |
| Consumption | 2,679 | 2,299 |
| Bronchitis | 860 | 639 |
| Pneumonia | 1,981 | 1,653 |
| Heart diseases | 711 | 413 |
| Marasmus and scrofula | 341 | 292 |
| Hydrocephalus and tubercular meningitis | 450 | 255 |
| Diseases of brain and nervous system | 1,703 | 1,455 |
| Apoplexy | 318 | 306 |
| Convulsions | 408 | 381 |
| Meningitis and encephalitis | 450 | 344 |
| Direct effects of the heat | 10 | 58 |
| Bright's disease | 833 | 697 |
| Suicide | 72 | 82 |
| Drowning | 88 | 143 |

BOYLSTON MEDICAL PRIZE.—It is announced that the above prize has been awarded to Herbert W. Page, F.R.C.S., Assistant Surgeon of St. Mary's Hospital, London, for a dissertation on "Injuries to the Back, without Apparent Mechanical Lesion, in their Surgical and Medico-Legal Relations." No prize was awarded for any dissertation on the first

subject proposed for 1881, "The Effect of Drugs, during Lactation, on either Nurse or Nursling."

This is the second time that the Boylston prize has been captured by an Englishman.

The following are the questions proposed for 1882:

I. Sewer Gas, so called (the Gas found in Sewers): What are its Physiological and Pathological Effects on Animals and Plants? An Experimental Inquiry.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of Three Hundred Dollars.

II. The Therapeutic Value of Food Administered Against, or Beyond, the Patient's Appetite or Inclination.

The author of a dissertation on the above subject, considered worthy of a prize, will be entitled to a premium of Two Hundred Dollars.

Dissertations on the above subjects must be transmitted, post-paid, to D. H. Storer, M.D., 182 Boylston St., Boston, Massachusetts, on or before the first Wednesday in April, 1882.

The following are the questions proposed for 1883:

I. Measles: German Measles and their Counterfeits.

II. The Differential Diagnosis of Abdominal Tumors; Especially those Connected with the Genito-Urinary Organs.

THE FIRST CASE OF YELLOW FEVER brought to New York this season was found on the steamer British Empire last week. The patient caught the disease in Havana. It is not expected that there will be much yellow fever here this summer.

THE PRESIDENT'S CONDITION at date of writing (August 3d) showed great improvement over that of a week ago. His pulse has kept between 94 and 100, his temperature has been normal in the morning with a slight rise, not often more than one degree, in the afternoon. Nourishment is well taken, and the patient sleeps without morphine. Quinine continues to be given. The wound has discharged healthy pus, and there have been no signs of obstruction or abscess-forming.

The most interesting event of the week was the attempt to locate the bullet by means of an induction balance, invented by Professor Bell. It is claimed that this apparatus has shown with reasonable certainty that the bullet lies in the front wall of the abdomen, about five inches to the right and below the umbilicus. It was near this place that a large ecchymosis is said to have appeared soon after the wound was first inflicted.

The instrument used for determining the position of the bullet consists of two flat coils about four inches in diameter, and one-half an inch in thickness, of insulated copper wire, a battery, a condenser, an interrupter, and a telephone. The ends of the primary or inducing coil are connected with the poles of the battery, and in the same circuit are a condenser and a small interrupter, whose vibrating tongue opens and closes the circuit with great rapidity. The ends of the secondary coil, in which the current is to be induced, are carried to the binding posts of a Bell telephone. When the connections have all thus been made, the secondary coil is laid on the primary or inducing coil, so that their respective circumferences exactly coincide. The circuit-breaker is then set in motion, and the rapidly interrupted current through the primary coil induces another current of higher intensity in the secondary coil, and as it does so a loud musical tone is heard in the telephone, with which the secondary coil is connected. As long as the current is maintained, and the circumferences of the two coils are kept in exact coincidence, the musical note in the telephone does not change its pitch or intensity. If, however, the experimenter slides the upper coil along an inch or so upon the lower, so that their circumferences no longer correspond, the intensity of the musical tone is diminished, and just in proportion as the centres of the flat coils are separated by a greater or less distance, the intensity of the musical tone is lessened or increased. When the upper coil is pushed over the lower so that they simply overlap, the centre of one corresponding nearly with a point on the circumference of the other, the musical tone in the telephone ceases. If the upper coil be pushed a little further to one side, so that it overlaps still less, the tone is again heard. By delicate manipulation it is possible to adjust the centres of the overlapping coils at such a distance one from the other that a perfect balance is brought about, and when this is the case the telephone makes no sound whatever. The centres of the overlapping coils cannot then be moved either toward or away from one another without causing the telephone to break its silence. When the coils are thus balanced and the telephone is mute, it is found that what may be called the area of coincidence, or in other words, the area of the overlapping parts of the two flat coils, has become highly sensitive to the approach of metal, and manifests its sensitiveness by a low note in the telephone. As long as metal is kept away from this area the telephone remains silent, but if a piece of lead, for example, is brought within a distance of four or five inches from the overlapping parts of the coils, there may be heard in the telephone a faint, but clearly perceptible note, which becomes louder and louder as the metal approaches the sensitive surface and throws the coils more and more out of balance.

Experiments have shown that a leaden bullet will excite a musical tone at a distance of between one and five inches, depending on the shape and size of the bullet.

In every case a very low musical tone was produced when the instrument was placed over the region of the abdomen indicated above. And nowhere else was the noise excited.

TREATMENT OF TETANUS. ISOLATION.—Regarding tetanus as an exaggerated reflex irritability of the spinal cord, provoked by various causes, Dr. Ria imposes strict isolation upon his patients, separating them from friends and relations, removing all possible sources of sensory disturbance, and carefully watching the influence of this treatment. Four cases have been cured. In one instance, chloroform in small quantities was applied externally by means of an atomizer, while to insure rest and slumber small doses of morphine and chloral were administered. In another instance, one-sixteenth of a grain of atropine was added to the chloral. The remaining two cases were treated by isolation and the administration of the bromide of potassium.

THE METRIC SYSTEM.—Dr. J. B. Stair, of Spring Green, Wis., writes: Sir—In answer to what Dr. Eames has said in the RECORD of June 4th, I will only say this: If we desire a system that *is* simply *practical* without being *mathematically* accurate, we had better retain the one we have by all means, for aside from the possible variation in our weights and measures—a condition likely to exist in any system

—our system is certainly not open to the objection of inaccuracy.

It is true that these inaccuracies are of minor importance practically, but if we admit, as Dr. Eames does, the fact of their existence, we also admit the utter fallacy of the great argument with which the system was once urged upon the profession—its exactness.

Despite Dr. Eames' notions to the contrary, I oppose the adoption of the new way conscientiously, and because I yet fail to see any necessity for its adoption. For myself, I can prescribe metrically quite as well as by the American plan, and it appears to me that it is about time those who advocate the metric system should cease to impute ignorance, prejudice, etc., to those who oppose it. Let us exercise less enthusiasm and more common sense.

BILLROTH'S PATIENT, ON WHOM HE FIRST PERFORMED EXCISION OF THE PYLORUS, recently died. The operation took place January 29th, and the patient lived for over three months. A post mortem was made, and it showed that death had taken place from metastatic deposits of cancer throughout the entire peritoneum, the duodenum and jejunum being likewise coated with a similar deposit. The stomach had retained its form, and showed few traces of the operation upon it. The woman had not suffered from any digestive troubles.

There is now, we believe, only one remaining of the patients that have been operated on for cancer of the pylorus.

EXTIRPATION OF THE LARYNX.—In regard to the operation performed by Dr. del Toro, of Cadiz, we have the following data. Laryngoscopic examination revealed a papilliform epithelioma, involving the entire posterior aspect of the epiglottis, the right aryteno-epiglottidean ligament, the right superior vocal cord, and part of the left. An incision was made in the median line, and both superior thyroids, the two linguals, and the left inferior thyroid artery were ligated. A cut was made through the crico-thyroid membrane, and through the cricoid cartilage posteriorly, leaving a circular ring of this cartilage. The body of the os hyoides and the base of the tongue were then extirpated, and the larynx removed. A silver canula was placed in the larynx, and a caoutchouc tube in the œsophagus. The operation was performed on March 9th. The patient continued well until the afternoon of the 12th, when he began to suffer from fever and extreme dyspnœa. He died on the 13th, at five o'clock in the afternoon, in consequence of a pulmonary emphysema—the only lesion revealed by the autopsy.

THE SUMMER CORPS OF TENEMENT HOUSE INSPECTORS during the past week visited 4,791 houses, containing 23,833 families, and prescribed for 1,038 patients, besides distributing free excursion tickets.

THE HEAT IN CINCINNATI.—During the week ending July 16th, there were 264 deaths from sunstroke, and 150 from the effects of the heat. There were 86 deaths from the heat in one day.

ANECDOTES OF SKODA.—In the *Staatszeitung*, Dr. L—— gives a short sketch of the life of the great master, the late Josef Skoda, the son of a locksmith, who was born in Pilsen, in the year 1805. His youth was one of hard struggles. At the age of twenty he repaired to Vienna, to pursue the study of medicine, graduating in 1831. His straitened circumstances induced him to accept a position as circuit physician, during the cholera epidemic in Bohemia, but subsequently he returned to the capital, where he entered the "Allgemeines Krankenhaus" as an assistant. His scientific career dates from this period. As early as 1835, we find him elucidating the mysteries of physical diagnosis to classes of eager students. In derisive allusion to his use of the stethoscope, the higher powers of the hospital conferred upon him the title of "the master with the little post-horn." His immortal work on auscultation and percussion, upon whose principles the diagnosis and management, not only of diseases of the thoracic viscera, but also of wounds of the abdominal organs are based, was ignored by those in authority. He afterward took charge of a newly established department for thoracic diseases. To the professorship he was not appointed until 1847, but long before this he contributed largely to the fame of the Vienna Medical School. From all parts of the world poured in those who were anxious to perfect themselves in auscultation and percussion; even gray-haired doctors condescended to play the student's role once more under Skoda. In 1848, at the founding of the Academie of Sciences, he became a member of the institution. In 1871, ill-health forced him to resign his professorship. Skoda was a man who never sugar-coated his bitter pills, but the public recognized the reliability of his diagnosis and the fact that his blunt manners and his precise way of speaking made him appear harsher than he intended. He remained single all his life; his unbounded love for science crowded out every desire for domestic happiness. When Rokitansky died, Skoda, bowed down with physical and mental pain, accompanied his friend's remains to the grave. "Why must *I* still live?" he said, in his calm but indescribably expressive way, to those who, with heavy hearts, endeavored to console him. Now he also has passed away. Skoda and Rokitansky will be remembered as long as man shall continue to study medicine. Never, in scientific history, have there been found two friends who criticised each other so impartially, and complimented each other's labors as thoroughly as these.

The journal mentioned also quotes several anecdotes about Skoda, some of which are a good index to his character. One day he was invited to dine at court. After having delivered his lectures and attended to his patients, he repaired thither in his customary, well-worn, old-fashioned apparel. "But the Herr Professor might have appeared with a frock-coat," reproachfully intimated the official charged with the reception of the guests. "Well, then," said Skoda, "I'll ride home and send my frock-coat here to dine." Upon another occasion, by ministerial decree, certain changes were to be made in the hospital, the utility of which Skoda denied, in spite of the Burgomaster's opinion to the contrary. "Your Excellency," he said bluntly, "we physicians are the best judges of such things." The angry retort that the government was paying the money, and intended exclusively to control it, was met by the argument that the funds belonged no more to the government than to the medical authorities, but that they were the property of the tax-paying multitude, who looked to the opinion of competent persons as to the disposal of them. Skoda, ever since his student days, was in the habit of attiring himself in exceedingly antiquated style. Decades passed by, but the cut of his "inexpressibles" remained the same, in spite of the bantering remarks of his friends. One day, however, to the great surprise and amusement of every one, the great clinician appeared in an elegant

pair of pantaloons, of faultless style. "As a student," he explained, "I lived with a tailor, who rendered me a good many services, and greatly assisted me, so I always remained his customer. He had his own antiquated notions about cutting goods, but I wore them as they were cut. The poor man is dead now, and *I*—have to wear fashionable pantaloons." For a pain in the foot, Skoda employed a salve prescribed by a colleague. Questioned as to the result of the treatment, he remarked, "Where I applied your salve, the pain was arrested, but where I did not, *it ceased much sooner.*"

PHOSPHATE OF SILVER as a substitute for the nitrate is to be given in doses of one-third to one one-half grain. It is claimed that it does not discolor the skin or produce gastric irritability. It is especially useful in subacute myelitis and scleroses.

ENFORCEMENT OF MEDICAL LAW.—The Board of Censors of the Medical Society of the County of New York is persistent in its determination to eradicate the evil of unlicensed practitioners and prescribing druggists. Action was brought against a certain Louis Widman, who was charged by plaintiffs with falsely registering as a graduate of Breslau, and of the Eclectic Medical College of this city. Although defendant held that he had studied seven months at the latter institution, examination before Judge Smith proved his inability to speak English. The grand jury discharged him, although the Board claims its evidence to have been sufficient to convict. In the case of De Kraft, who is registered as a graduate of the Electro-Therapeutic Institute of Philadelphia, 1868, the defendant swore that he cured by means of electricity and magnetism; this the court held was not practising medicine or surgery in the sense of the statutes. In the third case, one in regard to a prescribing druggist, decision has not yet been rendered.

AN ACT TO REGULATE MEDICAL PRACTICE IN PENNSYLVANIA has passed the State Legislature, and has been signed by the Governor.

The law much resembles that in this State. It compels all persons who are practising or who intend to practise medicine or surgery in Pennsylvania to appear before the prothonotary of the county, show that they have a degree from a legally incorporated medical college, and be registered by the clerk. Persons who have been continuously practising since 1871 will be allowed to register without a diploma. Persons from outside States must have their diplomas examined and countersigned by the dean of some medical college in the State.

Failure to register or registering fraudulently is punishable with a fine of $100, one-half going to the informer, as in this State.

The passage of the law is said to be largely due to the efforts of Dr. R. L. Sibbet, of Carlisle, chairman of the Committee on Medical Legislation.

THE FLUORIDES IN MEDICINE.—Dr. J. M. Da Costa (*Archives of Medicine*) has been making some experiments with the salts of fluorine. Fluoride of potassium, of sodium, and ferrous fluoride were the preparations chiefly tested. The fluoride of potassium was best borne and more used. This was given in doses of two or three grains. It was first given in a case of subacute rheumatism with considerable pain. The pain was considerably relieved without producing drowsiness. Gastric disturbance soon set in, however, and the drug had to be stopped. In other cases of rheumatism like effects were produced.

Reviewing the experiments, Dr. Da Costa says that the fluorides, especially the fluoride of potassium, in large doses are prompt emetics without depressing. They seem to relieve pain without producing sedation or sleep. They cannot be given long without producing gastric trouble. Their most singular effect, which is manifest especially with the iron salts, is the anorexia that is produced even by small doses. It is suggested that they may be of use in bulimia, or to counteract the craving for drink. On the whole, however, it seems unlikely that their therapeutic usefulness will be great.

ACTION AGAINST A "RATIONAL" MEDICAL COLLEGE.—From the *Buffalo Evening News* we learn that an action has been brought against Dr. Samuel W. Wetmore and *confrères* to restrain the College of Physicians and Surgeons, formerly Buffalo College of Rational Medicine from exercising the functions of a medical college. The action was brought to the notice of the State Attorney by the regular and the homœopathic societies of Erie County, and is in the nature of a *quo warranto*. By the former society, through the zealous efforts of whose older members a school of good standing and repute has been established, the above-named institution is held to be a bogus concern. The defendants claim to have been incorporated under the act of 1848, amended in 1871, relative to the formation of benevolent, charitable, scientific, and missionary societies. The complainants hold that no authority is given in these acts for the organization or incorporation of the institution in question. Prior to 1846 medical schools were founded in accordance with the provisions of special acts, but in 1853 a general provision was made for such incorporations, as alleged by the complainants. The Buffalo College of Physicians and Surgeons is not a benevolent, charitable, scientific, or missionary society in the sense of the Act of 1848, but a purely business corporation, operated for pay and profit, exercising the functions of a college of medicine and surgery. Its incorporation is provided for by the statute of 1853, now in force. The case is exciting considerable interest in the medical profession of Buffalo and vicinity.

THE AMERICAN OTOLOGICAL SOCIETY.—At the last annual meeting, held in Newport, R. I., July 26, 1881, the following gentlemen were elected officers for the ensuing year: Dr. J. Orne Green, of Boston, *President;* Dr. J. S. Prout, of Brooklyn, *Vice-President;* Dr. J. J. B. Vermyne, of New Bedford, Mass., *Secretary and Treasurer;* Drs. J. J. B. Vermyne, C. J. Blake, and J. Orne Green, *Committee on Publication;* Drs. John Green, of St. Louis, C. H. Burnett, of Philadelphia, and H. G. Miller, of Providence, *Committee on Membership.*

THE AMERICAN OPHTHALMOLOGICAL SOCIETY.—At the last annual meeting, held in Newport, R. I., July 27 and 28, 1881, the following gentlemen were elected officers for the ensuing year: Dr. H. D. Noyes, of New York, *President:* Dr. William F. Norris, of Philadelphia, *Vice-President;* Dr. Richard H. Derby, of New York, *Secretary and Treasurer;* Dr. J. S. Prout, of Brooklyn, *Corresponding Secretary;* Drs. E. G. Loring, D. B. St. John Roosa, and Richard H. Derby, *Committee on Publication.*

CREMATION.—A crowded meeting was recently held at Bologna, in favor of cremation. The medical profession has taken much interest in it, and it is expected that a crematory will soon be erected.

# Original Communications.

## IMPORTANCE OF THE EARLY RECOGNITION OF EPILEPSY.

An Essay read before the Connecticut State Medical Society, May 26, 1881.

By E. C. SEGUIN, M.D.,

NEW YORK.

(Continued from p. 144.)

The foregoing cases indicate that the error usually committed in judging of the true nature of first epileptic seizures is in considering them to be sympathetic convulsions, due to remediable causes—in other words, eclamptic attacks.

This capital diagnostic error is founded upon two erroneous conceptions, in my opinion:

1. A physiological misconception. In the first two years of life there is great convulsibility; the spinal axis is excessively irritable, and many causes, local, diathetic, and thermal, may produce convulsions. Thus, pneumonia, exanthemata, infantile spinal paralysis, intestinal worms, gastric irritation, gingivitis, sexual irritation, etc., may cause convulsive attacks, which are usually called eclamptic. If the cause be removed, such attacks do not recur. In the third and fourth years of life, more or less rapidly according to the constitution of the child, this mobile state of the spinal axis diminishes, the inhibitory cerebral influence is more and more shown, and the tendency to reflex spasmodic manifestations almost disappears.

The misconception lies in admitting, beyond the truly infantile age (three to four years), a liability to symptomatic or eclamptic convulsions.

There are exceptions, of course—some few children, and even adults (especially females), show convulsibility; but I believe that it may be stated, as a law most useful in estimating the significance of a first fit, that after the third or fourth years eclamptic attacks (except from uræmia) are excessively rare. A first rule for the study of convulsions then is, that convulsibility diminishes rapidly after the third year.

2. An etiological misconception, consisting in overestimating the exciting powers of local, internal, and peripheral causes. The doctrine of reflex neuroses, reflex neuralgia, reflex spasms, reflex paralyses, and of reflex psychoses, has fallen from the very high standing it acquired, mainly under the influence of Brown Séquard, some fifteen or twenty years ago. Reflex diseases of all kinds are now rarely reported by reliable observers, and more especially is this true of paralysis. That there are reflex nervous diseases I recognize, but I claim that they are not by any means so common as is usually believed.

More especially would I maintain this with respect to convulsions occurring after the third year of life. Cases of convulsions, or epilepsy, in individuals above three years of age, due to cuts, blows, worms, adherent prepuce, etc., abound in older medical writings, books, and journals; but in the last ten years physicians have become much more guarded, and such cases, when reported, are considered very interesting because of their rarity. Leaving out injuries about the head, I am not sure that I have met with such a case.

I would suggest, as a second safe rule in studying first convulsions, that, after the third year of life, local irritations, internal or external, are not likely to cause convulsions without the pre-existence of a morbid state of the nervous centres, inherited or acquired.

The terms eclamptic and epileptic as applied to convulsions accompanied by loss of consciousness, have been the source of great confusion. The words are often used as if they designated different symptom-groups, whereas, in reality, as sanctioned by observations and by the best authorities in our art, they mean the same symptom-group, occurring under different conditions.

I might support this statement by numerous citations, and by a minute description of a variety of attacks of each kind; but my time is short, and I will content myself with giving the opinion of a few authorities.

In the first place, Professor Trousseau says:*

"I have often known epilepsy and eclampsia to be confounded one with another, and I have also said that this confusion is almost inevitable, because, if we study only the convulsive manifestations of these two affections, they are indistinguishable.

"If you observe a woman attacked with eclampsia in the eighth or ninth month of pregnancy, or during confinement, or a child who is convulsed, either at the beginning of an eruptive fever or during dentition, however you may be on your guard—however careful you may be in your observations, you cannot make out any [symptomatic] differences between these attacks and the convulsive form of morbus caducus."

Dr. Day, in the recent edition of his excellent work on diseases of children,† quotes with approval Trousseau's statement as to the similarity of eclamptic and epileptic attacks—the latter being the former repeated in a series—and adds, when speaking of eclamptic attacks:

"In many respects they (the convulsions) resemble epilepsy, from which, indeed, they cannot invariably be distinguished."

An encyclopedic treatise on diseases of children is being issued in parts, in Germany, and the opinions of its numerous authors, all men of high standing, will be received with respect.‡

Dr. Otto Soltmann, of Breslau, in treating of epilepsy, says (p. 103):

"The eclamptic attack cannot be distinguished by its symptoms from the epileptic attack."

Nothnagel, an authority upon the subject of epilepsy, writes as follows of eclampsia, in Ziemssen's Cyclopædia:§

"What is there now remaining of what was formerly recognized as eclampsia? Are we altogether justified in still retaining the name? We believe so, and are of opinion that the title of eclampsia should be reserved as the name of an *independent affection*, which, it is true, can at present be defined only by its clinical symptoms. We propose that the designation eclampsia should be made use of for those cases of epileptiform spasms which—independently of positive organic diseases—present themselves as an independent acute malady, and in which, so far as our present knowledge allows us to judge, the same processes arise, generally in the way of reflex excitement, and the same mechanism in the estab-

* Clinique Médicale de l'Hôtel-Dieu de Paris. Seconde édition, vol. i., p. 88. Paris, 1865.

† The Diseases of Children, p. 607, American edition. Philadelphia 1881.

‡ Handbuch der Kinderkrankheiten: Herausgegeben von Dr. C. Gerhardt. Bd. v., Abth. i. 1ste Hälfte: Krankheiten des Nervensystems. Tübingen, 1879-80.

§ Cyclopædia of the Practice of Medicine. Edited by Prof. H. von Ziemssen. American edition. Article on Eclampsia, vol. xiv., pp. 201-2.

lishment of the paroxysms comes into play, as in the epileptic seizure itself. In this way, as we see, *the designation of eclampsia as an acute epilepsy finds greater authorization* [the italics are my own]; at the same time it is distinguished from true epilepsy by the lack of a persistent central change, which latter i npresses upon epilepsy the character of a chronic condition. In the case of eclampsia, where this chronic change is absent, the manifestations, the seizures disappear with the removal of the exciting irritation."

We may sum up these statements of high authorities by saying that eclamptic and epileptic attacks are similar in character and practically indistinguishable.

This being admitted as being true of the *symptoms*, we yet have the two *affections*, eclampsia and epilepsy, to differentiate; and it is this differentiation or differential diagnosis which is all-important for the welfare of our patient. It is not so very serious to consider eclampsia as epilepsy for a few months; but the converse mistake—the one illustrated by the cases I have read, the mistake which I believe is common, is in one sense fatal to the patient. The non-recognition of epilepsy allows of recurrence of paroxysms and the establishment of the epileptic habit.

Upon what grounds can a reasonably accurate diagnosis be made? I believe this can generally be done by attention to the physiological law of convulsibility, and to the relatively small importance of local irritations, internal and external, after the third year of life, as a cause of eclampsia. These two points have already been referred to at some length. A third rule which must be borne in mind is that at almost any period of life uræmia may cause eclampsia. This is more especially true of young subjects who have just passed through scarlatina with nephritis, or who have had symptoms of renal disease from any cause; and also of adults—males between thirty-five and fifty, who are liable to contraction of the kidneys.

A fourth diagnostic rule is that, in adults particularly, syphilis may cause eclampsia (*i.e.*, acute, curable epilepsy).

Plumbism and alcoholism sometimes cause eclampsia, but probably in most cases by producing renal changes and uræmia.

To apply these principles to practice, let us suppose cases of first convulsions with loss of consciousness, occurring in subjects of various ages.

1. Convulsive attacks in young children under three years.

If we can exclude injury to the head, gross organic disease of the brain, and microcephaly from premature closure of the fontanelles, the attack is probably eclamptic. This probability is increased to almost a certainty if we can accurately determine the existence of sufficient systemic or local causes for the attack.

Upon this question of sufficiency of the cause, much might be said. Often the physician is satisfied with merely determining the coincidence of a fit with a local irritation, or a supposed local irritation. Soltmann* is especially emphatic in his advice to judge these coexistent conditions carefully before pronouncing them to be causes, and the attacks to be merely eclamptic.

The occurrence of a single fit enhances the probability of its being the first seizure of epilepsy.

The occurrence of repeated attacks in the course of an hour or two makes it probable that the convulsions are caused by fever, by gingival, gastric, or intestinal irritation, or perhaps by some peripheral cause.

2. Convulsions in young persons from three to fifteen years of age.

These are quite certainly epileptic, if we can exclude renal disease. The occurrence of attacks of an eclamptic nature (*i.e.*, ephemeral and curable) in such subjects from intestinal, or gastric, or sexual irritation, is exceedingly rare, and the mistake—the terrible mistake of assuming such to be the pathology of convulsions, is frequently made, even by experienced physicians.

I would repeat, and the foregoing cases bear me out, that convulsions from worms, from indigestion, from lithæmia or oxaluria, in youth are exceedingly rare, and that in the treatment of such a case the patient should be given the benefit of the doubt and be put upon a rigid anti-epileptic treatment by means of bromides, while the treatment for the supposed local or diathetic cause is being carried out.

3. Convulsions in adolescents and adults.

These are to be judged by the same general rules as No. 2, with the addition that two morbid conditions should be carefully searched for, especially when the first convulsion occurs after twenty.

*a.* Syphilis. This may be acquired at almost any age, but especially after sixteen or eighteen years. Nothing in the social standing of the patient should deter the physician from inquiring delicately, yet deeply, into this question.

*b.* Chronic interstitial nephritis, more particularly in subjects of forty years and upward. The presence of a hard pulse, of over-action and hypertrophy of the heart, the passage of an excessive amount of urine of low specific gravity, sometimes containing albumen (never much), and a few hyaline or granular casts—these symptoms go to justify the diagnosis of contracted kidneys, consequent chronic uræmia, and the recurrence of eclamptic attacks.

If we exclude these two pathological conditions, a convulsion in an adult, especially if a single fit, is quite certainly epileptic, and will be followed by others, after a lapse of time which may vary from a few days to more than a year. Of course the existence of a long interval of health after one epileptic attack in no wise justifies a physician in pronouncing the disease not to be epilepsy, as is shown by some of the cases I have read, and by numerous others which I might cite.

To sum up the early diagnosis of convulsions:

1. After the third year such attacks are very probably epileptic. The possibility of uræmia and of syphilis should be borne in mind, and a careful investigation be made as to their existence.

2. Under the third year the attack may be eclamptic—probably is, but its causes should be carefully judged.

3. In many cases under three years it is well to give a moderate amount of bromide of potassium (or sodium) with regularity for several months after a convulsion, that is to say, in such cases as do not present an evident, indisputable pathological condition sufficient to cause eclampsia.

4. In all cases above three years the bromide treatment should be at once instituted and kept up for many months.

This will not interfere with the treatment by appropriate remedies and by hygiene of gastric or intestinal indigestion, of worms, of sexual irritation, of uræmia, and of syphilis.

* L. c., pp. 49–54.

Besides bromides, a variety of treatment is demanded by different forms of epilepsy, according to the pathological condition; but the consideration of these indications is foreign to this paper, whose main object is to encourage the prompt and proper treatment of epilepsy at the earliest possible moment, viz., in most cases after the first attack.

I am confident that, if this were done, the prognosis of convulsive epilepsy would be greatly changed for the better.

I now pass to the consideration of the diagnosis of petit-mal, consisting of epileptic vertigo (so called), and of imperfect or aborted spasmodic seizures.

In this category I do not include the localized or hemiplegic epileptic spasms, which I have treated of in a former paper.

Petit-mal, or epileptic vertigo is often allowed to pass for vertigo caused by indigestion. In my experience, physicians are very loath to call these slight attacks by the terrible name of epilepsy, and so delude themselves and their patients until the recurrence of a convulsive attack settles the question.

Besides, I find that, even when the attacks are recognized as epileptic, a most unfortunate statement is made that these are slight and manageable attacks, whereas the truth is that petit-mal is much more intractable than grand-mal, and often leads to more evident mental deterioration.

The correct diagnosis of petit-mal is feasible, provided a good description of the seizures be had.

From vertigo it is distinguished by:

1. The subjective phenomena. In vertigo there occurs a sensation as if the patient himself or objects about him were whirling around; in petit-mal there is no such feeling, but a sensation of confusion, or of something rising from the throat or epigastrium to the head. In some cases there are no sensations in the head beyond the consciousness that something is wrong for a moment.

The sensations of petit-mal are, moreover, usually sudden, or even flash-like, whereas in vertigo, cardiac syncope, and some hysterical attacks, there elapses quite a time in which the attack is growing. This suddenness of onset is very characteristic of minor epilepsy.

2. By objective phenomena. In faints and in some hysterical states the patient is limp from the start, and in other hysterical attacks there is spasm lasting many minutes. In petit-mal there is nearly always spasm, but not as in grand-mal. It usually expresses itself by a momentary rigidity of the whole body, with staring eyes and wide pupils. To express it otherwise, there is for an instant an unnatural immobility—the patient is, as it were, petrified for a few seconds. The friends of patients will usually accept the suggestion that the patient is statue-like in the attack.

It is to be borne in mind that in some cases the patient keeps his equilibrium, or even continues to walk. Nearly always, however, the action which the patient was doing at the moment (eating, talking, walking) is impeded or interrupted, to be resumed naturally after a few moments.

Some of these attacks of petit-mal are literally like a flash—just a moment's obscuration of consciousness. The consciousness is wholly lost in the various forms of petit-mal, though many patients will claim the contrary. The truth is usually easy to learn from the patient, or friends of the patient, and is at once evident if you happen to witness a paroxysm. I am in the habit of not relying upon an epileptic's statement that he is conscious during an attack, without sufficient corroborative testimony.

The dilatation of the pupils and their immobility, and the open state of the eyes, are capital symptoms.

In syncope and hysteria the eyes are closed and the muscles limber. The eyes in hysterical "faints" present an almost pathognomonic appearance; they are rather tightly closed, and present vibrations or quivering motions due to the prolonged effort at closure. In neither of these conditions is the pupil fixed and widely dilated, as in epilepsy; this is a symptom which cannot be imitated.

Vertigo from gastric disorder is characterized by a sense of whirling in the head, and often a sensation as if the ground were opening in front of the patient, or falling away from before him, with impending precipitation. The observer notices no dilatation of the pupils, or staring, or momentary stiffness of body; the patient can speak at any time. In severe cases the vertigo is very frequent and is produced by the least motion.

I cannot enter fully into a description, for diagnostic purposes, of each and every variety of petit-mal. This would take a long time.

Allow me to refer to the intermediate attacks, in which there is some jerking of one of the limbs, or in which the patient says or does something odd. In some cases the patient will rise suddenly from a chair, walk rapidly about, muttering something. In other cases the patient will lie back in his chair with the epileptic facies, and jerk both arms or the limbs on one side of the body for a few moments. In other cases, the patient being out of doors walking in the street, loses himself for a few blocks, and is surprised at his change of location. In other cases there may be incoherent or semi-coherent talking. Other patients simply stare and make swallowing movements, with or without drooling. Other patients fumble and fuss about with their hands, while staring and unconscious.

The unconsciousness and the attendant pupillary phenomena are the chief diagnostic symptoms in these cases; but a very important element in the differential diagnosis between these attacks and hysterical ones is that the latter present variations each time, whereas the mixed epileptic seizure is almost a stereotyped performance, one or two sets of movements being done by the unconscious subject.

Still other cases of non-spasmodic epilepsy occur in the shape of periodic or paroxysmal attacks of mania or melancholia. In some of these cases the careful observer finds that a nocturnal fit or an unobserved diurnal paroxysm ushers in the psychosis; but in other cases the mental disorder appears in a periodic epileptoid manner, and convulsions or petit-mal make their appearance later on.

I have already given it as my opinion, or rather as the summary of my experience, that petit-mal is often ignored for years, and is usually looked upon as a trivial affection.

It is my present purpose to urge the early recognition and careful treatment of this seemingly insignificant symptom. It appears to parents, and too often to physicians, as infinitely less serious than grand-mal or fits; yet I can assure you that the contrary is true.

Petit-mal, especially the flash-like form, is exceedingly rebellious to treatment. I have now several little patients who continue to have several "turns" a day, despite the use of as much bromide, etc., as their systems will bear. I have repeatedly had to produce severe bromism in order to barely control these

minor forms of epilepsy, and any reduction of the medicine to a safer dose was followed by a return of symptoms. In taking charge of a patient who has such petit-mal I always explain to the parents or relatives the difficulty of the task they have brought to me. In my experience, spasmodic attacks—even the most severe fits—can nearly always be controlled by a proper dosing of the bromides—they may also be suspended for months and years; but we have little control of the minor manifestations of the disease.

Still, in all forms of epilepsy the date of its recognition as epilepsy is an all-important factor in prognosis. By repeated seizures a condition of the nervous system (epileptic centre?) becomes established, which we designate as the epileptic habit, a condition which explains the remarkable fact that in some cases of symptomatic or reflex epilepsy the attacks continue after removal by surgical means of the morbid focus whence the attacks seemed to be produced.

By instituting treatment very early, if possible after the first or second attack, we eliminate this factor, and the chances of cure are greatly increased.

## OSTEOTOMY FOR GENU VALGUM.*

By C. T. POORE, M.D.,

SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, NEW YORK.

Section of bone for the correction of deformities of the lower extremities is not a new operation. It was performed in 1826 by Barton, of Philadelphia, for bony anchylosis of the knee-joint, but with an open wound; and Langenbeck, in 1852, performed a subcutaneous osteotomy of the femur for an anchylosis at the hip-joint, the section being made with a saw. In 1854 he performed a similar operation for rachitic deformities of the legs. Meyer, in 1851, divided the femur and tibia with a chain-saw, for the correction of an aggravated case of genu valgum. In May, 1876, Mr. Ogsten performed the operation that now bears his name, for the relief of genu valgum. Since then, osteotomy for this deformity has met with great favor among English and German surgeons, while in France it is scarcely ever practised, where osteoclasis has many advocates. In 1871 Delore practised forcible straightening of the limb, causing a separation of epiphysis of the femur or tibia, and within the past year Collin has devised an apparatus to accomplish the same end; it is said to do this with great precision. Delore's operation has failed to gain any advocates in England. In this country it has been attempted several times, but, I believe, with doubtful results.

Osteotomy for genu valgum was first performed in this country by Dr. Fowler, of Brooklyn, and since then by several members of this society. A discussion of the pathology of genu valgum is foreign to the object of this paper.

It is assumed that knock-knee is due to changes taking place in the plane of the condyles of the femur or head of the tibia, so that, in the former class, the internal condyle occupies a lower position than in the normal limb; that this is caused either by a bend in the lower third of the femur, by a true lengthening of the internal condyle, or by an atrophy or flattening of the external condyle—in the latter class similar changes may take place in the articular end of the tibia; and finally, changes may be found in the terminal ends of both bones. It is also assumed that the remote cause of the changes mentioned above, at least in children under ten years of age, is a rickety condition of the bones of the skeleton; and from the statement of Mr. Macewen, genu valgum coming on during adolescence may, in some cases, have a similar cause. Whether all cases belonging to the latter class are due to rickets, further observation must determine. I may add that, in a careful examination of nearly one hundred cases of this deformity, I have found but one case in which undoubted symptoms of rickets did not exist.

Having referred to immediate cause of genu valgum, the practical question to be solved is, how can this deformity be relieved? and is there any limit to the period at which we may hope to correct the deformity by mechanical means? Without going into the question of orthopedic appliances, it may be said that, while the bones are soft—before that ossification peculiar to rachitic bones has taken place—correction can be made; if, however, this period has passed, or we fail to make any impression upon the deformity within a few months, splints are worse than useless, and our only resource is in osteotomy. There have been seven cutting operations devised, namely:

*First.*—A section below the tubercle of the tibia (Shede).

*Second.*—A section of the internal condyle with a saw, the joint being entered (Ogsten).

*Third.*—A section of the internal condyle with a chisel, the joint not being necessarily entered by the instrument, but probably fractured into (Reeves).

*Fourth.*—The removal of a V-shaped piece from the internal condyle, its apex being directed downward and outward (Chiene).

*Fifth.*—A section of the shaft of the femur just above the epiphyseal line (Macewen).

*Sixth.*—A section of the shaft of both femur and tibia (Barwill).

*Seventh.*—A section of the shaft of the femur from the outside (Taylor's).

Of these operations, I have personal experience in only two, namely: the division of the internal condyle with a chisel (Reeves's), and the section of the shaft of the femur from the inner side (Macewen's). Mr. Reeves performs the operation in the following manner: an oblique incision is made above the inner tuberosity of the femur, down to the bone, a chisel is introduced, and the internal condyle separated down to the cartilage; the limb is then forcibly straightened. The object of the operation is to make a section of the internal condyle in a line running from a short distance above the epiphyseal cartilage to the inner side of the intercondyloid notch, the line being as near the perpendicular as possible; otherwise the partially detached bone will not slide up readily, and difficulty will be experienced in making the correction. The operation aims to plant the condyle higher up, and thus make its lower tip correspond to its position in the normal limb. The articular surface of the femur is left irregular. This, in some cases, at least, is afterward filled in with osseous and fibrous tissue. I have performed, or attempted to perform, this operation in five limbs: once successfully, once partially so, and in three I failed to make the correction.

It is evident that, in order to be able to slide the internal condyle up, it must be freely divided,

* Read before the New York Surgical Society, May 10, 1881.

and that the ligaments holding the tibia in apposition to the external condyle must be not only unrelaxed, but sufficiently strong not to stretch during the bending inward of the tibia, which must be used as a lever to cause the displacement of the partially detached condyle. In the three limbs on which I failed to displace the condyle, the external and crucial ligaments were so altered that they permitted the tibia to assume its normal position without making any impression on the position of the condyle, and I was deceived by this apparent correction. Again, it is not an easy section to make, and it is difficult to know just where the cutting edge of the chisel is, and from this fact it takes longer to complete the operation. In cases where the internal condyle is very much lengthened (as in the palm I now show, taken from a case recently operated upon), the condyle would have to be so much displaced, in order to correct the deformity, that the articular surface of the femur would be very uneven, and I would fear the functions of the joint might be seriously crippled. There is no question but that Reeves's operation, in cases not very marked, has given excellent results. In my first case, the deformity was completely overcome, and the functions of the joint perfect. I think, also, that the limb can be used earlier than after any other operation. While, therefore, the theory on which Mr. Reeves based his operation would seem, in some cases, to be correct and the more perfect, yet they are outweighed, I think, by the difficulty mentioned above. I have, therefore, in my last twelve cases, abandoned it, and adopted that of Mr. Macewen, of Glasgow, which he describes as follows: the limb having been rendered bloodless, laid in an extended position on a sand-pillow, and with strict antiseptic precautions according to Mr. Lister's method, an incision is made down to the bone, at a point where the two following lines meet: one drawn transversely a finger's-breadth above the superior tip of the external con-

FIG. 1.

FIG. 2.

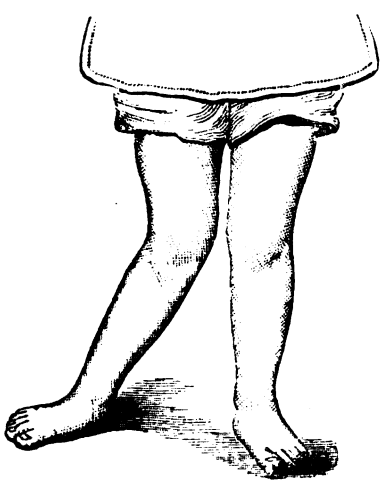

FIG. 3.

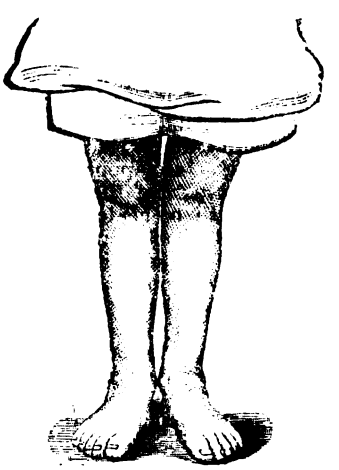

FIG. 4.

dyle, and a longitudinal one drawn half an inch in front of the adductor magnus tendon, the incision is made sufficient to admit the largest osteotome and the finger, if the operator desires it. Before withdrawing the knife, the largest osteotome is slipped by its side until it reaches the bone. It is then turned at right angles to the long axis of the limb, and the instrument is made to penetrate the bone. After the inner portion of the bone is divided, a finer instrument may be slipped over the first, which is then withdrawn, and a third, if necessary, may take the place of the second, when the outer portion of the bone comes to be divided. After penetrating the inner, anterior, and posterior portions of the bone, and the operator thinks that sufficient of the external shell has been divided, the osteotome is laid aside, and the wound covered with a sponge saturated with a one to forty watery solution of carbolic acid, the point of section is grasped with one hand, the leg with the other; using the latter as a lever, it is jerked if the bone is hard, or bent slowly if the bone is soft, in an inward direction, when it will snap or bend, as the case may be. After bandaging the sponge over the wound, the webbing is removed and the other limb operated upon. Before dressing, he ascertains whether any cellular tissue is so prominent as to protrude beyond the lips of the wound. If this is the case, it is excised, as he thinks that it will prevent the wound from healing by an organized clot, and will favor suppuration. Lister's dressings are then applied, and the limb placed in a kind of fracture-box, its outer portion extending up to the third or fourth rib.

If the temperature keeps normal, and there is no pain in the limb, it is left undisturbed for a fortnight, and is then placed in a well-padded splint for several weeks longer. He thinks that ten weeks are necessary from the time of the operation until the patient is able to walk freely. The object of the operation is to divide the shaft of the femur above the epiphyseal line with an osteotome, the form of the incision in the bone being wedge-shaped, with its apex directed outward, the bony tissue on either side of the cutting instrument being condensed by the shape of the chisel. If the deformity is not great in straightening, the two sides of the V-shaped cut are simply brought into apposition and no hiatus is left on the outer aspect of the limb; if, however, much correction has to be made, the outer portion of the shaft is made to contribute to rectify the deformity, and an angle is left with its apex directed inward. The aim of the operator in the after-treatment of the case is to obtain immediate union of the cutaneous wound—in other words, to convert the compound into a simple fracture, and to retain the limb in its corrected position until firm bony union has been obtained.

I have been rather minute in describing Mr. Macewen's method of operating and mode of treating the wound, because I find that certain rules may be abandoned without any detriment to the patient, and with much comfort and advantage to the operator.

*And first*, in regard to the use of the spray: so far as my experience goes, I cannot see that it in any way contributes to the immediate closing of the wound, or to the freedom from suppuration. I have performed seventeen osteotomies for genu valgum: one, strictly antiseptic, the wound was reduced to a mere ulcer on the seventh day; there was slight suppuration. In sixteen osteotomies done without the spray, the wound being kept damp in some cases with a one to forty carbolized water solution while operating, and after completing the section syringing it out with a one to forty solution of carbolic acid, in four cases (eight limbs) where the wound was examined on the third day, in seven the wound was closed, and in one case there was slight suppuration. Of the remaining, two limbs were not looked at until the splint was finally removed; the wounds were found closed and showed no mark of having suppurated. Two were opened on the fifteenth day, two on the twelfth, and two on the seventh. In only one of these was there considerable suppuration, to which reference will be made later. Thus, in sixteen limbs operated upon without the spray, the wounds may be said to have closed in all but three limbs by the third day. In regard to the temperature, in only one case was it above 99.5° during the two weeks, and then it rose to 102° for one evening in two cases—no cause could be assigned for it. I may add that in osteotomy for bow legs, I have very often seen the temperature suddenly rise to 102° or 103° during the latter part of the second or beginning of the third week after the operation, and as suddenly go down, for which no cause could be found. From some remarks of Mr. Macewen I infer that a rectal temperature of 101° is seen in some cases.

*Second.*—Mr. Macewen operates with the limb in an extended position. In all my operations the leg has been strongly flexed and the thigh rotated outward. I think that one can get at the bone easier, and obtain a firmer bed to place it on. There is another advantage, that after the section, then the limb is extended, the tissues between the skin and bone slide forward and shut off the point of section in the femur from the cutaneous wound. Thus, in case suppuration should take place, it is subcutaneous. The ridge of bone running from the tubercle for the attachment of the tendon of the adductor magnus backward and upward, I think, is an easier point to cut down upon, and a better landmark for the longitudinal incision than "a point half an inch in front of the adductor magnus tendon." The suggestion of Mr. Macewen, to remove with scissors any piece of cellular tissue or fat that may protrude between the edges of the wound in the skin, is a valuable one, and upon this alone, it seems to me, depends the rapid closing of the cutaneous wound and the freedom from suppuration. In those cases where I have had suppuration I neglected to take this precaution, and I attribute the tardy union to this cause. A piece of adhesive plaster about one-half the width of the wound, and several inches long, I have placed over the incision to better approximate the edges. I have used it in my later cases, and I think it has been an advantage in aiding immediate union. This gives sufficient room on either side to allow the escape of any collection of blood that might do harm. Mr. Macewen seems to think that in his case the wounds were closed by an organized clot of blood—in other words, by plugging. I think that in those cases where I got early union it was by perfect coaptation and absolute rest. It does not seem probable that a clot of blood would become "organized" by the third day. After having completed the section of the second limb, I syringe out the wound in the first limb with a one to forty watery solution of carbolic acid, apply the adhesive plaster, and over this a compress of Lister gauze about three inches square, then a bandage, and over this a plaster-of-Paris splint extending from the foot nearly to the perineum. The limb is then held in a

straight position until the plaster has hardened, after which the patient is put to bed. On the third day I cut a fenestra over the point of incision, remove the compress, and look at the wound. I do this because in one case I had quite an extensive abscess, subcutaneous, extending upward from the point of section as far as the upper third of the thigh, and this without any elevation of temperature to mark its advent. It did not connect with the bone. My explanation of its formation is as follows: there was a small piece of tissue protruding from between the lips of the wound; against this was the compress. Suppuration, slight at first, took place, but the gauze, being full of dry blood, did not absorb it, but rather dammed it in. It then increased, separated the lips of the wound, and then dissected a cavity for itself, as mentioned above.

In those cases where the bone is very hard, or where the deformity is marked, it will be impossible to make the correction without a complete fracture of the bone, and in these cases care should be taken in putting the limb up that there is no lateral displacement of the fragments. I noticed this condition in one of my cases. In one case I had to make a section of the tibia just below the tubercle, in addition to the section of the femur. The hemorrhage from an osteotomy is slight. After putting up the limb there is generally enough oozing to come through the plaster-of-Paris bandage and discolor it. I have never used any drainage. There is not much pain after the operation; the patients are generally sitting up in bed on the following day. Those cases where there is much relaxation of the ligaments about the knee-joint are not as favorable ones for osteotomy as those in which this condition does not exist. In all my cases, after a Macewen's operation, that are up, the patients are able to stand with the malleoli touching. A sufficient time has not elapsed in my own cases to determine the permanency of the cure.

In order to add further proof to the statement that the spray gives no additional protection against suppuration and elevation of temperature, I would like to record the fact that, in thirty osteotomies on the tibia and fibula, twenty-six of which were performed without the spray, in only three or four have I had any suppurations, and the temperature has kept about normal.

The accompanying cuts are from photographs of patients presented to the society at the time of reading the paper; they show the results obtained by the operation, and exhibit the amount of deformity.

---

A Case of Prolapse of the Female Urethra.—A case in which this rare condition was found is reported by Dr. James Hudson, of New Zealand, in the *British Medical Journal*. The patient was a married woman, thirty years of age, who suffered from incontinence of urine. The prolapse was very marked. It was reduced with the finger, and the urine drawn off for several days. Pieces of the mucous membrane came away. Cicatrization took place, and the patient had no further trouble.

Hamamelis has long been a popular domestic remedy, and is being much used by the profession. Internally, in bleeding piles, it is very efficient. As a local application, in irritable and inflamed external piles, it has no equal, according to Mr. Netherclift. It is also a most useful wash for old ulcers.—*British Medical Journal.*

## LOCATION, AGE, AND SEX IN POTT'S DISEASE OF THE SPINE.*

By HENRY LING TAYLOR, Ph.D., M.D.,

NEW YORK.

"Pott's Disease" is a name sometimes given to a carious ulceration of the vertebral bodies and their intervertebral disks, which often goes on to extensive destruction of these parts, and consequent angular deformity.

I propose to study the comparative frequency of occurrence of this disease in the several regions of the spinal column by an analysis of the records of several hundred cases in the private practice of Dr. C. Fayette Taylor, of New York.

It is at once conceded that the only absolutely accurate way to determine the location of a spinal caries is to rely on post-mortem findings, but unfortunately the number of accurate autopsies is too small to give trustworthy results. It is obviously a somewhat rough method to count the projecting spines and assume a caries of the corresponding vertebræ, as the morbid process must commence before there is any projection, and with a given deformity the disease may extend beyond the projection both upward and downward.

These objections, however, are more apparent than real, for the few cases which are observed before there is any spinal projection either go on to have deformities, which enables the observer to locate the disease, or are not reckoned at all in a table of localization, and, being as apt to occur in one region as another, do not affect the result. We must also remember that only a moderate length of time is necessary, after the first appearance of rational signs, to bring on a modification (bulging or flattening, according to the region) of the normal spinal contour readily appreciable to the practised eye.

In regard to the second source of error—the extension of the caries beyond the limits of the deformity—we can only say that it will affect the result more as to the number of vertebræ involved, making it too small, than as to the locality; though, as the disease has a tendency to spread downward rather more than upward, the average resulting location might be somewhat too high.

The main point after all is: Does the apex of the spinal projection indicate with tolerable accuracy the centre of the focus of disintegration? I think that an appeal to the post-mortem table and to dried specimens will show us that the correspondence is close enough to make statistics based on a physical examination of the living body of value in this connection.

As these records were made at the beginning of treatment, and the cases came in every stage of the disease (with perhaps an average duration of from eighteen months to two years), the question arises: What will be the effect on our results and conclusions, of tabulating all together?

Reflection shows that, if we considered only the beginning cases, where the trouble was confined to one or two vertebræ and found a marked preference for certain regions, this would be more distinctly indicated in the figures than in an analysis of cases which had progressed farther in their disease—we will say to spontaneous cure. The most obvious difference would be in the number of vertebræ in-

* Thesis submitted for graduation to the Faculty of College of Physicians and Surgeons, New York, May, 1881.

volved. My statistics covering, as they do, a mean between these two extremes, ought to give an intermediate result.

I found in the records the results of examination stated in two ways: either the region only was given, or the individual vertebræ were specified. I recorded these two sets of cases separately, and made note of the region in those cases where the vertebræ were given.

In order to check my work, I made separate tables of the first and second halves of the cases, in the order in which they were recorded.

I found three hundred cases of Pott's disease recorded, where a diagnosis as to the individual vertebræ involved had been made.

I append the result of classification in the following table (I.), the first two columns being the separate tabulation of the first and second one hundred and fifty cases, as a check; the third, the combined result.

TABLE I.

| Vertebræ. | | 1. Vertebræ affected in first 150 cases of Pott's disease. | 2. Vertebræ affected in second 150 cases of Pott's disease. | 3. Vertebræ affected in 300 cases of Pott's disease. |
|---|---|---|---|---|
| Cervical: | 1 | — | — | — |
| | 2 | — | 2 | 2 |

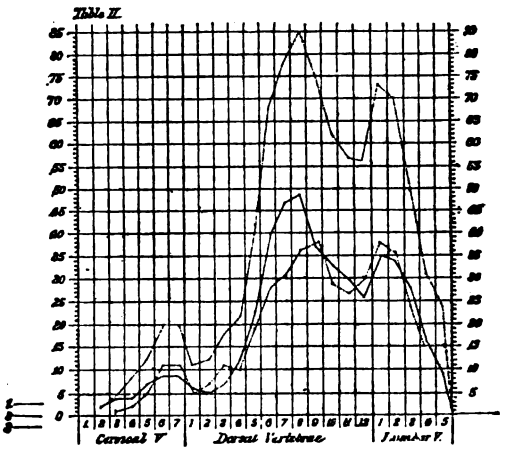
| | 5 | 15 | 9 | 24 |
| | | Total lumbar..128 | 121 | 249 |
| | | | | Average, 5.0. |
| Lumbo-sacral articulation... | | | 1 | 1 |
| Total vertebræ affected.....429 | | | 471 | 900 |
| | | | | Average, 37½. |

It will be seen that the correspondence between Columns 1 and 2 is very close, not only in the totals for the different regions, but also in the individual vertebræ, showing that the number of cases is large enough to serve as a basis for generalization.

The discussion of these results will be facilitated if we translate Table I. into the graphical language by constructing curves (one for each vertical column of figures) whose abscissæ shall correspond to the vertebræ, and whose ordinates shall represent the numbers in the table (1), in degrees of an arbitrary scale.

In Table II. I have constructed such curves. The interrupted line (1) corresponds to Column 1 of Table I., the continuous black line (2) to Column 2, and the red line (3) to Column 3. We have thus presented to the eye, for comparison at a single glance, the results of Table I.

It will be seen that Curves 1 and 2 coincide as regards all their well-marked features, so that we



may at once proceed to the consideration of their combination—Curve 3, which we may call the curve of liability in Pott's disease.

The curve ascends from the second cervical to the sixth and seventh cervical, falls to the first dorsal, rapidly rises again to the eighth dorsal, falls to the eleventh and twelfth dorsal, rises to the first lumbar, and finally falls to the lumbo-sacral articulation.

In plain language, in three hundred cases of Pott's disease every vertebra in the spinal column was several times diseased (except the first cervical, and it is conceded that the diagnosis of the exact seat of the disease in the upper two to three cervical vertebræ is attended with considerable difficulty).

Further, there are three centres of maximum liability to the disease: one at the sixth and seventh cervical vertebræ, about one-third the size of the two succeeding; one extending from the eighth dorsal vertebra as a centre a short distance up and down; and one of nearly equal magnitude at the first and second lumbar.

Besides the two extremities of the spine, there are two loci of least liability, viz., at the first to the fourth dorsal, and at the eleventh and twelfth dorsal.

That the curve is a continuously progressive one, gradually rising to its maxima and descending to its minima, is a strong confirmation of the value of the results; for, if it were very irregular, rising and sinking very suddenly between adjacent vertebræ, it would suggest the suspicion that the method of diagnosis was too defective, or the cases too few to admit of generalization.

Referring to Table I., we find that there were in 300 cases of Pott's disease 65 cervical, 586 dorsal, and 249 lumbar vertebræ involved, making 900 vertebræ in all, or an average of three to each case. As before remarked, these cases were examined at varying periods of the disease, the average previous duration being perhaps eighteen months to two years. The average liability of a cervical vertebra, in 300

cases, is 9 (got by dividing the number of cervical vertebræ diseased in 300 cases [Table I.] by the number of cervical vertebræ, 7). Similarly, the average liability in the dorsal region is 49, and in the lumbar 50; these figures are to each other nearly as 1 : 5 : 5.

Let us now discuss the different regions as a whole, without reference to the individual vertebræ. Here, as before, in order to check the work, I made separate notes of the first and second half of the cases, which, including the three hundred cases already given, were three hundred and sixty-four in number.

TABLE III.

A.

| Region diseased. | 1. In first 182 cases of Pott's disease. | 2. In second 182 cases of Pott's disease. | 3. In 364 cases of Pott's disease. |
|---|---|---|---|
| Disease in cervical region. | 21 | 22 | 43 |
| Disease in dorsal region .. | 122 | 107 | 229 |
| Disease in lumbar region.. | 73 | 76 | 149 |

Of the above, some had the disease in more than one region, as follows:

B.

| Region diseased. | 1. In first 182 cases of Pott's disease. | 2. In second 182 cases of Pott's disease. | 3. In 364 cases of Pott's disease. |
|---|---|---|---|
| Both cervical and dorsal... | 5 | 6 | 11 |
| Both cervical and lumbar.. | 3 | — | 3 |
| Both dorsal and lumbar ... | 24 | 17 | 41 |
| Cervical, dorsal, and lumbar | 1 | — | 1 |

Section B of this table is included in A, and cases which have the disease in more than one region are noted *once for each* region in Section A.

Here again we note the very close correspondence between Columns 1 and 2 of the table (III.), showing that these results are the expression of a general law. If we divide as before (p. 176) the numbers in Column 3 (Table III.) by the number of vertebræ in the corresponding region, we shall get the average liability (in 364 cases) of a single vertebra. We thus obtain the numbers 6, 19, 29, or approximately 1, 3, 5 as the expression of the relative liability to the disease of any single vertebra in the cervical, dorsal, or lumbar region respectively. The corresponding numbers obtained from Table I. (vide p. 176) were 1 : 5 : 5. These numbers agree very well, as it is only possible for them to coincide when the number of vertebræ affected in one region does not differ from the number in any other; but observation shows us what these figures indicate, that if the disease is in the dorsal region the number of vertebræ involved is usually considerably greater than when it is in the cervical or lumbar. This is explicable on mechanical principles.

To sum up our results in a word, we have the liability to the disease increasing from the extremities to the middle—eighth dorsal vertebra—of the spinal column; with breaks only at the upper—first, second, and third—and lower—tenth, eleventh, twelfth—dorsal vertebræ.

Can we assign any reason for the greater immunity of the vertebræ at the extremities of the spinal column and of the dorsal region?

Let us assume, for the present, that traumatism is the most important exciting cause of Pott's disease, and see if a discussion of the mechanics of the spinal column on this hypothesis will throw any light on the question.

On examining a side view of the spinal column such as that shown in Holden's "Osteology" * (Plate VI.), we find, as is well known, that the spine is concave backward in the cervical and lumbar regions, convex backward in the dorsal. It will be easily admitted that the dorsal convexity is the most vulnerable district in the spinal column for blows from behind and falls backward; moreover, being connected with the sternum by the ribs and their cartilages, it is possible, though very improbable, owing to the elasticity of these structures, that violence applied in front and at the sides might be transmitted to the bodies of the vertebræ to which they are attached. Moreover, the cervical and lumbar regions, besides being withdrawn from violence by their concavity, and having no osseous connections which could transmit violence inflicted anteriorly, are well covered with a thick, muscular pad, and the upper cervical and lower lumbar are materially protected by adjacent osseous structures—the former by the jutting occiput, the latter by the sacrum and iliac crests.

There is, however, another important factor, namely, the pressure of the superincumbent mass, which rapidly increases as we go downward, and which would render many kinds of violence, as that transmitted from below in jumping, and falls on the limbs and ischia, much more effective in lower than in the upper regions of the spinal column. This would tend to neutralize the advantage which the lumbar region enjoys by its position, but would add to the immunity of the cervical region. It is interesting to find that the most prominent (and hence most exposed) part of the dorsal region, as shown in Holden's plate (VI.), corresponds exactly with the region of maximum liability in the table, namely, the seventh and eighth vertebræ.

In regard to the greater immunity of the upper and lower dorsal vertebræ than those adjacent, we find that the former are protected by the prominent scapular masses on either side, which operate to ward off direct violence; and further, that the upper extremity is not firmly connected with the vertebral column, as is the leg; on the contrary, blows and falls on the shoulder tend to explode on the clavicle and sternum.

The immunity of the lower dorsal vertebræ is not greater than we should suppose, from considerations already given, but is accentuated by the very great liability of the upper lumbar vertebræ. Can this greater liability not be explained by the fact that at this point is the great natural hinge, so to say, between the upper and lower halves of the body?

That this hinge does exist can be seen from the character of the dorso-lumbar articulations, which is more enarthrodial than any others in the spinal column, and from the great stiffness of the dorsal articulations.

The strain comes there (upper lumbar region) in lifting and carrying heavy loads, in wrenches and all sorts of violence, where the upper and lower halves of the body act as two distinct masses hinged together, as in wrestling, etc.

These considerations, I think, coincide very beautifully with the ascertained liability to Pott's disease, deduced from statistical analysis, and at the same time greatly strengthen the growing belief in its traumatic origin in the majority of cases.

My table contains no cases of carious disease of

* Luther Holden: Human Osteology. Fourth edition. London: John Churchill & Sons, 1869.

the atlas; but since the table was constructed a case of atlo-axial disease has come under the care of Dr. Taylor, and in the MEDICAL RECORD of November 13, 1880, may be found the report of an autopsy on a case of occipito-atlantal disease. In Holmes' "System" * (vol. iv., p. 140) will be found a cut of a specimen of atlo-axial disease. In my table is included one case of sacro-lumbar disease; so that we may safely say that the entire spinal column is liable to this disease.

Surgical authorities generally indicate the dorsal region as most liable. Erichsen† gives the middle dorsal; Bryant,‡ the lower dorsal; Gross,§ the second, third, and fourth dorsal, and also believes that the cervical vertebræ are more frequently affected than the lumbar. Holmes * makes no statement in regard to location, nor do most of the treatises of specialists, such as Lee,‖ Shaffer,¶ Sayre,** etc., so far as I have been able to discover.

Bampfield's†† classic monograph, almost the first ray of light since Pott's work, is defective on account of his topographical classification of spinal deformities. He gives (p. 142) the three to four lumbar as the favorite seat of an "angular projection," but states (p. 16) that curvatures of the spine, in which he includes "lateral curvature," most commonly occur in the dorsal region. Kormann‡‡ is silent on this point. Taylor§§ says (p. 6) that "the relative frequency in the three regions varies only a little."

I will conclude by briefly considering age and sex as a modifying element in Pott's disease.

*Age.*—In 375 cases of which the ages are given, I found the following distribution of ages at the beginning of their disease, or rather at the time when the first symptoms were noticed. I separate, for comparison, the first 200 and the last 175 cases.

TABLE IV.

| Age at which first symptom appeared. | 1. Out of 200 cases. | 2. Out of 175 cases. | 3. Out of 375 cases. | 4. Number of persons living in 375. |
|---|---|---|---|---|
| Under 5 years. ..... | 119 | 107 | 226 | 54 |
| From 5 to 10 years..... | 40 | 28 | 68 | 47 |
| " 10 to 15 " ..... | 10 | 14 | 24 | 47 |
| " 15 to 20 " ..... | 9 | 11 | 20 | 39 |
| " 20 to 30 " ..... | 10 | 6 | 16 | 65 |
| " 30 to 40 " ..... | 9 | 4 | 13 | 47 |
| " 40 to 50 " ..... | 3 | 4 | 7 | 34 |
| Over 50 years ..... | .... | 1 | 1 | 42 |
| | 200 | 175 | 375 | 375 |
| There were under 2 years.. | 39 | 38 | 77 | 21 |

In Column 4 of the table (IV.) I have added, for comparison, the number of persons that would be living at each period out of 375, as calculated (from the total population of the United States) from Table XXII. of vol. ii. of the "Ninth United States Census Report."

We find from the table (IV.) that it is only under ten years of age that the number of cases of Pott's disease exceeds that of people at that age, taken at random from the population. We find that of 375 cases 226 were under five years of age when the disease began, while 149 were over that age; these numbers are to each other as 3 to 2. Of the 226 under five, 77 were under two years, and in four cases the disease could be referred to the sixth or seventh month of life; 338, or about nine-tenths of the whole number occurred before twenty, while only half the population at large is under twenty; 8 occurred after the patient had reached forty years of age, and 1 over fifty; the last occurred in the cervical region, in a man seventy-two years of age.

Bryant * mentions a specimen (Preparation No. 1004.92, Guy's Hospital Museum) showing Pott's disease in the dorsal region in a fœtus, so that it seems possible for the disease to be initiated at any age.

Whether the proneness of early childhood to this disease be a result of the greater softness of the osseous structures at that period, I must leave to others to decide.

The results given agree very well with the statements of the leading surgical authorities, *vide* Sayre,† Holmes,‡ Erichsen,§ Gross,‖ Kormann.¶ Mr. Pott, according to Bampfield,** never saw it in a subject over forty.

*Sex.*—I found 412 cases in which the sex was recorded, of which 235 were males and 177 females, or as 9 to 7. This bears out Dr. Sayres' † assertion that "it occurs more frequently among boys than among girls." Whether his explanation of this preponderance, viz., that it is due to a greater exposure to accidents (which I deem likely), be true or not, this proportion is about ten times greater than the preponderance of white males of all ages in the United States, according to Table XXVI., vol. xi., "United States Census Report of 1870," and even more for children under ten, where four-fifths of our cases occurred.

---

THE TROUBLES OF A PHYSIOLOGIST.—The distinguished physiologist Paul Bert, successor to the chair of Claude Bernard, was recently summoned before the Tribunal of the Seine to respond to an action brought against him by Mme. Greyot. This lady petitioned for damages to the amount of 16,000 francs, asserting that the unendurable howling of the experimenter's dogs had driven the guests from her establishment. On the part of the defendant it was claimed that, upon the receipt of complaint, efforts had been made to remedy the evil. Bert had even gone so far as to render the animals mute by operative procedures. The aphonia of the canines having been demonstrated to the satisfaction of the court, the plaintiff's petition was denied, and Mme. Greyot was condemned to pay costs.

## ASTIGMATISM.

By C. A. BUCKLIN, M.D.,

NEW YORK.

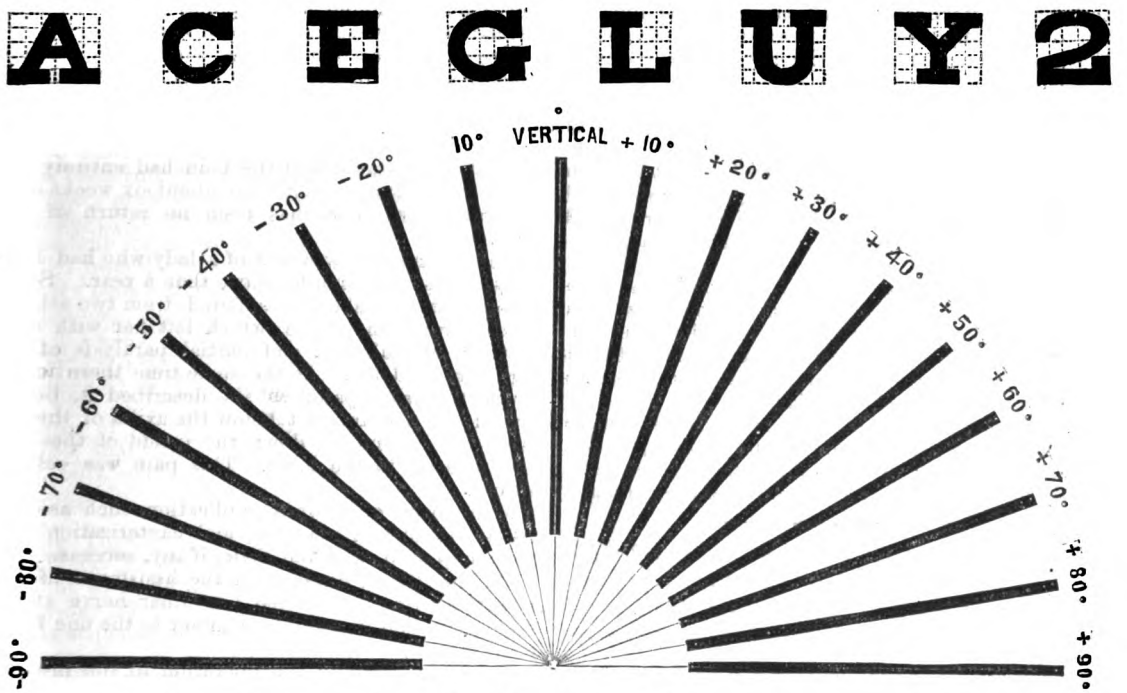
The cornea of man should be nearly spherical. It sometimes happens that it is of a decidedly ovoid form, which necessitates the curve in one meridian being considerably sharper than the other. The cornea being a portion of a lens system which casts a distinct image of observed objects upon our retina, it is readily seen that, in the meridian having the sharpest curve, the rays of light will be acted upon more strongly than in the meridian which has a flat curve; consequently, an observed object is confused and distorted in the direction of the *sharp corneal curve*, thus: the sharp curve of the cornea being in the vertical meridian, a pin-hole in a card through which light comes to us will appear *vertically oval*, and will only appear *nearly* round when the observed opening is made sufficiently oval in the horizontal meridian to correspond with its magnified diameter in the vertical meridian. I find many who were supposed to be afflicted, "*disease of the optic nerve*," "*imperfect entrance of the optic nerve.*"*

"*Amaurosis*," "*amblyopia*, etc.," are suffering from the optical effects of a faulty cornea *usually* causing regular astigmatism.

The irregularities in our crystalline lens is the commonest cause of what is called *irregular astigmatism*, an optical defect which is not correctible, which we all have to a greater or less extent, and without which we would all be able to see the moons of Jupiter with our naked eye. *Mechanics* are frequently found who can never file anything square; an opening or piece of metal which is square appears longer in one direction than the other, and it is not till the piece of metal *is longer* in the direction of the flat corneal curve that it appears square. Artists, students, and all classes who use their eyes constantly, frequently suffer from this defect.

Failing to receive any benefit from simple spherical lenses, they naturally suppose that their eyes are diseased. These individuals make the lives of spectacle-sellers uncomfortable by their constant *unsuccessful* efforts to obtain glasses. They dislike to look at striped goods, particularly when the abnormal curve lies in any of the quadrants between the horizontal and vertical meridians. It is particularly difficult for them to read in the evening, and they are constantly making remarks about how poorly they see without a very strong light.

The diagnosis of astigmatism is usually readily made if one is suspecting it. It almost invariably reduces the acuteness of distant vision. The line of letters here given should be read, at twenty feet at least, with the greatest ease. It is the universal standard for testing distant vision.



At the most distant point at which these letters are *perfectly* distinct, the radiating lines should all appear equally *dark* and *distinct*. If the vertical curve of the cornea is the sharpest, the horizontal lines will appear magnified and blacker until the vertical curve becomes so sharp that the magnification of the horizontal lines blur them. The vertical lines will then retain their natural thickness and remain distinct, but are never magnified under these circumstances; it is only when the horizontal curve is the sharper one, that the vertical lines may be magnified. A given meridian of the cornea being abnormally flat, the rays of light falling on this meridian will be united behind the retina; consequently, lines whose *thickness* is estimated by this meridian are indistinct.

The flat corneal curve being in the horizontal meridian, the *horizontal* lines will be the blackest.

Persons who can read the above letters with ease

* The above condition was really given as a diagnosis by an ophthalmoscopist. If such a condition exists, there is nothing known about it.

at twenty feet, to whom the radiating lines all appear equally dark, and who still have weak vision caused by astigmatism, are very rare.

Persons who are quite far-sighted are obliged to accommodate strongly for distant objects, and do not show their astigmatism till the *unusual* amount of accommodation is forcibly dispensed with by giving convex lenses, which neutralize their hyperopia. They are thus prevented from compensating for the faulty structure of their corneas by changing the form of their lenses.

I have observed one case (and I think the only one observed) where, owing to a choroiditis, the rods and cones of the retina had been sufficiently separated to produce the phenomenon of "*small vision;*" the horizontal dimensions of objects were particularly small; a cylindrical lens with axis vertical greatly improved the vision, and was of most decided relief to the patient.

The fact that, at the most distant point at which the square letters can be read, the radiating lines do not look equally black, is good ground for supposing that reduced acuteness of vision or weak vision is caused by faulty corneal curves.

The defect is corrected in the following manner: where the vertical curve is too sharp, a piece of glass ground on the convex surface of a cylinder is placed before the eye with the axis horizontal; such a lens acts only upon rays of light in the vertical meridian, and can be ground with just the required curve to compensate for the abnormally sharp corneal curve.

When the horizontal meridian is too flat, a piece of glass ground on the concave side of a section of a cylinder is placed before the eye with the axis vertical. Other visual imperfections may be corrected at the same time by grinding on the other side of the cylindrical lens the requisite lens.

How these radiating lines appear to an astigmatic person may be readily seen by pressing upon the upper part of the eye-ball with the fingers sufficiantly to increase the vertical curve of the cornea.

## NERVE-STRETCHING AS A RADICAL CURE FOR PAIN.

By GRÆME M. HAMMOND, M.D.,

PHYSICIAN TO THE DEPARTMENT FOR NERVOUS DISEASES IN THE METROPOLITAN THROAT HOSPITAL.

So much has lately been written concerning the efficacy of nerve-stretching for various affections, and the results, to a great extent, have been so satisfactory, that the two cases I am about to report may not be without a certain amount of interest to the profession.

In both of these cases there was intense pain in those parts of the arm, forearm and hand supplied by the ulnar nerve.

Drs. Fenger and Lee, in their exhaustive article on "Nerve-Stretching, which appeared in the *Journal of Nervous and Mental Diseases*, April, 1881, report two cases in which the ulnar nerve was stretched for neuralgia.

The first case was operated on by Vogt, in 1878. The patient suffered from a "neuralgia after wound on the inner side of the forearm, involving the ulnar nerve. The incision was made in the scar, and the ulnar nerve dissected out and stretched. The operation was followed by immediate and permanent relief."

The second operation was performed by Czerny, 1879. In this case there was "neuralgia subsequent to suppuration around the elbow-joint. The ulnar nerve was stretched in the axillary plexus. The patient's condition was ameliorated, but the recovery was not perfect."

The first case that came under my observation was that of a man forty-five years of age, who presented himself for treatment at the Department for Nervous Diseases in the Metropolitan Throat Hospital. He stated that, on election day, in order to emphasize his remarks, he struck his clenched hand two or three times very forcibly on the table.

Three days afterward he was seized with violent pains involving the middle, ring and little fingers, and the ulnar side of the forearm of the right side. On May 29th, with the assistance of Dr. Henry Norris, I operated on him at the hospital. I made an incision about three inches in length midway between the internal condyle and the olecranon process of the ulnar.

I selected this position for the incision as the nerve is easily found at this point, and is unaccompanied by any vessels of large size.

The nerve was found in its usual position, and, placing a large director under it, I gently raised it until it yielded in both directions. The nerve was then replaced, and the wound sewed up.

As soon as he had recovered from the effects of the ether, he stated that the pain had entirely left him. Up to the present time, about six weeks after the operation, there has been no return of the pain.

The second case was that of a lady who had been under my supervision for more than a year. Some seven years ago she had suffered from two attacks of cerebral hemorrhage, which left her with difficulty in articulation, and partial paralysis of the right arm and leg. At the same time there was a severe "tearing pain," as she described it, beginning from a point just below the axilla of the left arm, and continuing down the inside of the arm and forearm to the hand. This pain was seldom absent.

Many forms of outward application, such as electricity, liniments, massage, and cauterization had been employed, with but little, if any, success.

On the 7th of June, with the assistance of Dr. Henry Norris, I stretched her ulnar nerve at the same place and in a similar manner to the one I had previously operated on.

From the time of the operation to the present moment, with the exception of slight soreness about the region of the wounds, there has been no pain whatever.

The good results reported by Drs. Fenger and Lee, and the successful termination of these two cases of my own, lead me to believe that cases of neuralgia, not due to a distinctive process in the nerve itself, or to pressure on the nerve, or where the nerve-stretching is not carried to too great an extent, will in most cases find permanent relief from this simple operation.

A Grateful Patient.—Not often is there recorded such an illustration of gratitude toward the physician as was shown by Thomas Hobson, aged seventy-eight, who hanged himself in the Prestwich workhouse, England, after having made a will bequeathing his body to his medical attendant, "in gratitude for his kindness and urbanity." The doctor did not accept the bequest, however, but turned it over to the School of Anatomy, at Owens College.

# Progress of Medical Science.

A Hitherto Undescribed Disease of Childhood.—Antonio Rigo reports (*Il Movimento med.-chir.*, No. 1, 1881) numerous cases of a peculiar affection which has been prevalent in Terra di Lavoro during the last sixty to seventy years. Its most characteristic feature consists in the formation of a pearl-gray, false membrane, of the size of a pea up to that of a centesimo, on the under surface of the tongue anywhere between the tip and frenulum. It is adherent to the mucous membrane, above the level of which it is but little prominent, and, on being torn off, while causing only slight hemorrhage, exposes an ulcerated base, which becomes covered with a new membrane in a day or two, despite cauterization with nitrate of silver. The rest of the mucous membrane of the mouth is not affected, there is no fœtor ex ore, no swelling of the tongue or adjacent lymphatic glands, and no interference with nursing. The disease occurs only during the summer months, is always associated with intestinal catarrh, and is fatal in ninety per cent. of the cases, death being due to inanition. The affection is confined to nurslings, occurring most frequently in the period immediately preceding the first dentition, and is not contagious, but infectious. It does not appear to be dependent upon any constitutional anomaly inherited from the parents, although these are usually country people living under the most impoverished conditions. The author has not met with the disease in its first stage, nor has he been able to make any post-mortem examinations or microscopical investigations of the false membrane. Its non-identity with diphtheria is established by the clinical features of the disease, and more particularly by the fact that diphtheritis has occurred in the district only since the last decennium.—*Allgem. med. Central-Zeitung*, May 28, 1881.

The Therapeutic Uses of Nitrite of Amyl.—Dr. Edgar Kurz, of Florence, has found this medicament so useful in the various aches and pains of every-day life that he has persuaded many families of his acquaintance to keep it on hand as a domestic remedy. It is an excellent external application for stomach-ache, colic, tooth-ache (whether nervous or arising from caries), neuralgia of the trigeminus, of the cervico-brachial plexus, etc. It is superior to anything else when inhaled in so-called angio-spastic hemicrania, giving rapid relief in the individual paroxysms and prolonging the intervals between the latter. No trial was made in cases of angio-paralytic hemicrania, since in this affection the drug would be physiologically contra-indicated. It has a very good effect in dysmenorrhœa, especially when occurring in chlorotic girls; in mild cases external applications suffice, otherwise the drug should be inhaled (when complicated with inflammatory conditions of the uterus or appendages the results were doubtful or negative). Its physiological action being that of a paralyzing agent of the muscular tissue of the blood-vessels, with consequent dilatation of their calibre (most marked in the upper half of the body), nitrite of amyl is theoretically indicated in all conditions of cerebral anæmia. Practically it was found to be of much value in attacks of dizziness and faintness occurring in anæmic individuals, as also in a fainting-fit from renal colic, and in several cases of collapse during anæsthesia by chloroform.

It has been recommended in asphyxia from drowning, hanging, and in asphyxia of the new-born. But the first indication in these cases is the induction of artificial respiration, after the successful initiation of which inhalations of nitrite of amyl doubtless assist in overcoming the concomitant spasm of the smaller arteries.

One of the most important indications for the use of the drug is threatening paralysis of the heart from insufficient compensation. In such cases it is necessary to gain time until digitalis and alcoholics can unfold their action, and here nitrite of amyl stands pre-eminent. A single case in point will suffice to illustrate this. The patient was suffering from mitral insufficiency, with irregular pulse, loss of appetite, enlargement of the liver, and mild jaundice. Temporary relief had been several times afforded by infusion of digitalis. In February, 1879, the condition of the patient suddenly became aggravated. The pulse became very irregular and intermittent. The condition described as delirium cordis presented itself, together with epigastric pulsation and vomiting. Vigorous counter-irritation, by means of hot bottles and sinapisms to the extremities, etc., proved useless. Digitalis and champagne, when administered, were immediately vomited. The pulse ran up from seventy until it could no longer be counted at the wrist, while the beats of the heart increased to one hundred and twenty and more per minute. The extremities grew cold, and the face became covered with perspiration. The urine was highly albuminous. Nitrite of amyl was then administered by inhalation: at first, three to five drops; then, ten to twenty; and finally, more or less was poured on the handkerchief without being measured. During each inhalation the condition of the patient rapidly improved, but as quickly grew worse, so that the drug was continued at short intervals all night, ten grammes in all having been used. In the morning the patient was better, and 0.5 grammes of digitalis was then given in infusion per rectum, and repeated on the following day, after which the patient remained comparatively well until a year and a half later, when a second attack of the kind just described was quickly cut short by similar treatment.

Another noteworthy case was that of a robust man of thirty years, who was attacked with acute gastro-intestinal catarrh. The patient had as many as one hundred watery evacuations in forty-eight hours, with fainting-fits, violent cramps in the calves of the legs, two attacks of general convulsions—in short, he presented the picture of a person attacked with cholera. Opium, champagne, hypodermic injections of sulphuric ether, counter-irritation, etc., proved useless. The doctor was on the point of injecting dilute liq. ammonii into the veins, but, none being obtainable, it occurred to him to try nitrite of amyl as a last resort. A considerable amount was poured on a handkerchief and held before the patient's mouth and nose, while the legs were also rubbed energetically with the same agent. Respiration soon became deeper and more regular, while the pulse gradually returned at the wrist. These procedures were repeated again and again, without regard to the quantity of the drug used, as soon as the radial pulse became weaker, and kept up until the patient complained of a sense of fulness in the head, and requested the discontinuance of the drug. The evacuations became less frequent, and in a week the patient was able to be up. Re-

suming then, Kurz concludes that nitrite of amyl is indicated in cardiac affections when the capillary circulation is obstructed and the cardiac muscle is threatened with paralysis from overwork; further, in cases of impeded circulation occasioned by cholera or severe diarrhœa, particularly in the so-called hydrocephaloid (false hydrocephalus) of children. It is worthy of trial in tetanic and eclamptic seizures, and in tonic angiospasms such as occurs during the chill of malarial fevers, although in the last-mentioned condition pilocarpine is perhaps more suitable, provided the energy of the heart be unimpaired.

As regards the dose, Kurz's experience demonstrates that we need not restrict ourselves to a few drops. The quantity may be increased, if necessary, until symptoms of cerebral congestion show themselves, when the drug should be momentarily or permanently discontinued. Usually from three to five or ten drops are sufficient, sometimes even less. Kurz has met with no unpleasant consequences, much less serious complications, from the application of nitrite of amyl. But the drug is contraindicated in cases associated with cerebral hyperæmia, in atheromatous conditions of the arteries, and in the so-called plethoric state.—*Betz's Memorabilien*, March 24, 1881.

Treatment of Neuralgia and Hyperæsthesia of the Ovary.—Dumontpallier (*Gazette Hebdom.*, 1879, p. 733) found that in many cases of neuralgia and rheumatic arthritis the pain was quickly relieved by hypodermic injections of water, or by the mere introduction of a needle at a corresponding point on the opposite side of the body, while the same manœuvres were less effective when applied directly over the seat of pain. Taking a hint from these results, Seeligmüller adopted the same treatment in a case of very intense pain and tenderness of the left ovary, complicated with cataleptic symptoms, etc., in a girl of twenty years. The patient was in a condition of chronic morphism, having received hypodermic injections of 0.04 gramme and upwards of morphia, one or more times a day, for several years. Under the pretence that the skin of the left side was so riddled with punctures as to be no longer suitable for injections, Seeligmüller injected water with a slight admixture of acetic and carbolic acids, over the region of the right ovary, with the result of relieving the patient's sufferings as effectually as had been previously accomplished by morphia. The effect, although only palliative, was promptly manifested at every succeeding injection. Seeligmüller believes that these peculiar results are rendered somewhat comprehensible by the observations which have been made regarding the phenomena of transfer ("*Transfert*"), which make it probable that every part of the body stands in reflex communication with a corresponding point of the opposite side. —*Med.-chirurg. Rundschau*, March, 1881.

Significance of Myelin, Pigment, and Epithelial Cells in the Sputum.—Dr. Oscar Panizzo has made a series of experiments in the laboratory of Prof. Ziemssen, in Munich, in order to determine the physiological and pathological importance of the above-mentioned constituents of the sputa, and has arrived at the following conclusions:

*First.*—Myelin is only a name for the external appearance of a large number of very different substances. It may be produced artificially by the mixing of oleic acid and ammonia, olive-oil and ammonia, salivary mucus and benzol, etc. When found in the sputa or on the mucous membrane of the respiratory tract, it is a form of mucin, which is evacuated from the goblet-cells either as free myelin or under the form of myelin-cells. The latter, in the course of their amœboid movements, take up particles of dust, soot, and other foreign bodies, and thus become transformed into pigmented myelin-cells. These are the so-called granulated pigment-cells (Pigmentkönnchenzellen) to be found in the sputa of people after inhaling dust. They can always be found on healthy mucous membranes which are lined with ciliated epithelium, and in the sputa. Occasionally, even pus, mucus, and epithelial cells, in any part of the respiratory tract, may become converted into pigmented myelin-cells by a process of mucino-myelinic metamorphosis.

*Second.*—When epithelia from the pulmonary alveoli have undergone pathological changes, they cannot be distinguished in the sputum from epithelia of other derivation which have been altered by similar pathological alterations. (This disposes of Buhl's assertion that he can diagnosticate incipient desquamative pneumonia—the most common variety of phthisis—by the mere presence in the sputa of altered alveolar epithelium).

*Third.*—Micrococci of various sizes, and often aggregated like sarcina, are always present in the epithelium of the mouth in healthy people.—*Deutsches Archiv für klin. Med.*, April 25, 1881.

Massage for the Relief of Tabetic Anæsthesia. —Schreiber reports a case of locomotor ataxia in an advanced stage, with moderate ataxia, lancinating pains, gastric crises, paralysis of the abducens nerve, and complete anæsthesia of both gluteal regions. Having previously convinced himself that massage was capable of curing the anæsthesia which often presents itself in the course of neuralgia, especially sciatic, Schreiber resolved to try this treatment in the case under consideration, although it has been heretofore held that mechanical treatment is to be avoided in locomotor ataxia. In daily sittings of five minutes' duration, the affected parts were kneaded and stroked with the clenched fist in various directions. The manipulations were performed with only moderate force, and did not cause the slightest pain. After a lapse of twelve days the anæsthesia, which had existed five months without any intermissions, disappeared entirely. Upon what physiological basis this effect rests it is impossible at present to say. Tuerk was the first to point out that rubbing was sufficient to relieve mild cases of anæsthesia, and he asserted that the benefit derivable from salves and liniments were in a great measure attributable to the conjoined mechanical manipulations.—*Med.-chirurg. Rundschau*, April, 1881.

The Prevention of Ophthalmia Neonatorum.— Like most lying-in institutions, the maternity hospital at Leipzig has constantly had to do with a large number of cases of virulent conjunctivitis of the newborn, amounting to as much as eight or ten per cent. of the whole number of infants born in the building. Crédé at first endeavored to combat this state of affairs by repeatedly washing out the vagina in parturient women with disinfectants, but met with scant success. Of late a more effectual prophylaxis has been secured by instilling into each eye, immediately after delivery, one drop of a two per cent. solution of nitrate of silver, the eyes being constantly covered during the succeeding twenty-four hours with compresses dipped in a two per cent. solution of salicylic acid. Out of two hundred infants treated

in this way only one became affected, and it was shown in this instance that the prescribed directions had been neglected. It made no difference in the results whether disinfectant vaginal irrigations were employed or not. Ohlshausen, of Halle, has been less successful in preventing the development of this scourge of the new-born, although he has been able to reduce the morbility from 8.8 to 3.6 per cent. He directs the eyelid to be carefully washed before the infant has opened its eyes, the conjunctival sac to be wiped out with a clean wad of cotton, and then washed with a one per cent. aqueous solution of carbolic acid. Should one eye become diseased, the arms of the infant are at once bandaged to prevent its inoculating the other eye, and the infant is laid on the affected side.—*Archiv für Gynäkol.*, Bd. xvii., Heft 1; *Centralblatt für Gynäkol.*, No. 2, 1881; *Med-chirurg. Rundschau*, April, 1881.

Bloodless Method of Treating Atheromata.—Following Panas' good results in cases of ranula, Scharnowski has treated eleven cases of atheroma (sebaceous cyst) by injections of several drops of a ten per cent. solution of chloride of zinc into the centre of the tumor. In the first patient the cyst was situated upon the upper eyelid, and measured four centimetres in diameter; the first injection was followed by moderate tumefaction and local elevation of temperature, which passed off in about five days, after which the tumor underwent marked diminution in size, and was made to disappear completely after three more injections, given at intervals of five days. The remaining cases were equally successful, from three to nine injections being required, at intervals of five to seven days. In no case was the formation of an abscess caused by this method of treatment.—*Vratsch*, No. 49, 1880; *Med.-chirurg. Rundschau*, April, 1881.

Mycosis of the Trachea.—Herterich's patient was a young man of nineteen years, presenting the symptoms of a mild pharyngeal catarrh. Physical examination of the chest gave negative results. Every eight or ten days the patient coughed up a rather consistent lump of glassy, gray mucus, in the centre of which was imbedded a solid body of the size of a bean, resembling a kidney in shape, with one smooth and no opposed rough surface. The central mass had a gray color, with shades of yellow and green, crumbled readily, and on microscopical examination was found to consist almost exclusively of *eurotium aspergillus*. Examination with the laryngoscope disclosed a healthy larynx, but diffuse deep injection of the bronchial mucous membrane. At the level of the sixth, seventh, and eighth cartilaginous rings, on the anterior wall and extending to the left, the mucous membrane was moderately tumefied. In this situation as well as in the region below, as far as the lower border of the ninth tracheal ring, the parts were the seat of deep purple injection and superficial excoriation, but no adherent mucus and no false membrane were seen. Lower down the hyperæmia disappeared.

Herterich assumed that the peculiar sputum was generated at the swollen parts of the bronchial mucous membrane; in fact, daily examination with the laryngoscope enabled him to verify this supposition. Inhalation of carbolic acid exercised no influence on the course of the affection, which was entirely cured, however, by inhalations of iodine, given thrice daily for several minutes; during fourteen days.—*Aerztlich. Intelligenzblatt*, No. 43, 1880; *Med.-chirurg. Rundschau*, April, 1881.

Early Resection in Tubercular Disease of the Joints.—At the last Congress of German Surgeons, as reported in the supplement of the *Centralblatt für Chirurgie*, No. 20, 1881, Koenig read a paper on the above subject. He divided cases of tubercular joint disease into two classes, namely: those in which there is, at an early period, extensive destruction of the tissues of the joint, with formation of caseous abcesses and great disturbance of the mechanism of the articulation; and those which apply for treatment before the cavity of the joint is invaded, the disease being restricted to the articular ends of the bones, with the addition, perhaps, of peri-articular abcesses. In the former variety there can be no doubt that resection is the only proper treatment. As regards the second class of cases, while many endorse resection, Koenig does not practise it, because the operation is by no means a guarantee against subsequent general tuberculosis, either theoretically or clinically. Moreover, he has been able, by conservative and orthopedic treatment, to bring about a definite cure of such cases, with the retention of perfect or very good function of the joint. Under conservative treatment, Koenig seems, from the tenor of his remarks, to include erasion, évidement, and other similar procedures.

In the very animated discussion which ensued, and in which Sonnenburg, Hueter, Klebs, Schede, Kraske (Volkman's first assistant), and others took part, the greatest diversity of opinion was manifested. As regards the anatomical appearances of tubercles, the weight of opinion seemed to be that their presence was not sufficiently characteristic to distinguish tubercular from scrofulous, syphilitic, and non-specific neoplasms. Respecting the value of inoculation to determine the tubercular nature of suspicious granulations or other elements, Klebs and Rosenbach asserted that such experiments gave positive results. If genuine tubercle were employed, local tuberculosis developed in a large number of cases at the site of inoculation, while general miliary tuberculosis not infrequently followed. On the other hand, Schede stated that he and Friedlaender had frequently introduced tuberculous masses into the peritoneal cavity of rabbits, and always with negative results. Thiersch, in closing the discussion, thought that it was at present impossible to arrive at any unanimity of opinion on the subject, but he hoped that in the near future sufficient data would be furnished us for the formation of definite conclusions on this most important topic.

Fatty Tumor of the Tongue.—At the Charité Hospital, M. Gosselin recently observed a rare form of lingual neoplasm, consisting of a true lipoma. The patient was a man aged forty eight years, who had first noticed a little button at the tip of his tongue, and to the right, when twenty-three years old. Very gradually the tumor had increased in bulk. Special symptoms or inconvenience were not developed; nevertheless, for the past two years phonation had become somewhat impaired. The neoplasm had attained about the size of a walnut, had a distinct pédicle, and did not appear to extend into and between the lingual muscles. At the surface of this submucous growth some ulceration had taken place. The operation consisted of simple ablation. The microscope confirmed the naked-eye diagnosis, and the mucous membrane covering the lipoma was found to be unaltered.—*Lyon Médical*, April 3, 1881.

# THE MEDICAL RECORD:

## A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 13, 1881.

## CONCERNING PRIZE COMMITTEES.

THE reports of prize committees are so often to the effect that no essay worthy of award was offered, that we are led naturally to inquire into the reason for such a state of things. While the facts, as given by the committees, may tend to show that prizes are not easily earned, they also prove, to a certain extent at least, that the ambition of the working element of the profession is being turned into other and more profitable channels. While we are willing to admit the truth of the former assumption, we are inclined to give more weight to the latter than would at first appear to be warrantable. We are glad to think that, as a rule, the prizes offered are hard to win, but it is far from gratifying to suppose that it is still more difficult to enlist the interest of the proper workers. The latter is oftener the reason why prizes are not won than the mere fact that they are difficult to obtain. There are not wanting many explanations for all this which apply with peculiar force to the manner of prize-giving in this country.

In the first place, the prizes are small compared with the amount of work which is exacted of the competitor. As a rule, or, at least, in the large majority of cases, the mere pecuniary reward, trivial as it generally is, is all that the victor can claim, aside from a casual mention in the society's proceedings, and a tardy and restricted publication in the Transactions of said body. It is needless to say that many of the most valuable and original researches are thus buried, to the disappointment of the author, and to the detriment of the profession. One trial of this kind, on the part of any writer, is enough to convince him of the inutility of making another, and his experience does not go for naught with other active and ambitious workers. It is true, that this dog in the manger spirit, on the part of many societies, is giving way to the real necessities of the hour, but the rule forbidding the outside publication of society proceedings, and more especially prize essays, is still quite general. And such a law inflicts penalties on the very ones it intends to benefit. The man who writes for a prize has the main object in view of deriving for his labor the greatest obtainable benefit. He certainly does this by securing the largest possible reading of his essay. When he is hindered in so doing, there is but one result to anticipate. No man cares to throw away valuable original work for the sake of benefiting a society of which he may be a member—virtually delivering over, for a paltry consideration, the right and title to use his brain-product to an organization which avowedly has no other aim than that of its own petty glorification. Hence it is that societies, whose membership comprise some of the best working talent in the profession, have, year after year, nothing for their prize committees to do.

Another reason why these negative reports concerning prizes won are so often made, is, that the subjects chosen are not such as invite investigation and study. Some of the themes are not only poorly selected, but are of such a character as to make intelligent investigation of them impracticable, if not impossible.

Then again, the conditions in regard to the prize are oftentimes so difficult of reasonable fulfilment, as to deter the right men from entering the lists altogether. Much better would it be in all cases to leave the selection of a subject to the competitor, and allow him to treat it in his own way. Under such circumstances the aspirants would throw in their best efforts, and give the results of study which had been stimulated by their surroundings and influenced by their opportunities.

It is no disparagement to the judgment of the majority of gentlemen who serve on such committees to say, that they are not always capable of deciding as to the real merits of the essays offered. Not very infrequently, subjects are presented to them of which they cannot possibly have the necessary expert knowledge, and concerning which they can have no opinion as to their relative or positive merits. More than one instance of this kind has come to our knowledge where essays have been rejected, when afterward published have called forth the unqualified commendations of the medical critics, and have been voted the merit of original research and the high distinction of a valuable addition to medical literature. We confess that it is not only often difficult but sometimes impossible to find competent experts who are willing to pass upon the merits of any essay for the mere accommodation of a prize committee. But this is hardly a reason why such attempts should not be made in the cause of justice to one who labors conscientiously as a candidate for a prize.

Nor does it seem fair that the conditions as to the probable knowledge of authorship should be

strictly enforced in all instances. Often it is impossible to hide the identity of an author in the discussion of a subject with which he is especially familiar, and of which he is generally competent to express an opinion. Under such circumstances, his very fitness to do the best work would disqualify him for obtaining what should otherwise be his legitimate reward. The fear of partiality by the committee is not so great as the possible injustice to a candidate who may choose a topic that unfortunately betrays him.

---

MEDICAL MISSIONARIES.

THE Edinburgh Medical Missionary Society is about to send out eight qualified medical men as medical missionaries to different parts of the world. The Zenana and Medical Mission of London is doing the same kind of work. It has been, and is now, training women to be missionaries, giving them at the same time a fair medical knowledge. Most of these lady missionaries will go to India, where the opportunity for their work is immense. There are in that country many millions of women who are entirely ignorant of how to care for their health. They are also cut off by the customs of the country from male medical advice, even if it were otherwise attainable.

In the United States similar efforts to send out medical missionaries are being made. The Woman's Missionary Society of this city has appealed to the students of the Woman's College of the New York Infirmary, asking that some may fit themselves for missionary work. The same appeal has, we understand, been made to other colleges, and not without success.

Even from a sectarian point of view, it can easily be seen that the opportunities for doing good by carrying medical and sanitary knowledge into pagan lands are immense. And this fact is being appreciated. The number of medical missionaries is now said to be rapidly increasing. Twenty years ago there were fewer than thirty physicians who were agents of missionary societies; now they number a hundred, or more.

Some of the greatest successes in the missionary field have been achieved through the activity of these men. In India, China, Japan, and Syria they have done especially good work. No little addition to medical science has come from the same source. The medical college in Beirut, Syria, and the medical mission hospital at Foochow, Japan, furnish some of the evidences of this. The RECORD has from time to time chronicled some of the work of the men connected with these institutions. It is a gratification to know that a class of persons who will have such large opportunities to serve their fellowmen, as well as their Master is steadily increasing.

And here, we might add, is another opening for our over-supply of young medical men. Indeed, as one gazes upon the crowded benches of our commercial medical schools, it is impossible not to think how much good some of those young men could do in India—and how little here.

---

DOCTORS' SIGNS.

"CONSIDERING our present advanced state of culture, and how the torch of science has now been brandished and borne about, with more or less effect, for five thousand years and upward; it must strike the reflective mind with some surprise that hitherto little or nothing of a fundamental character has been written on the subject of Doctors' Signs."

Much has been said about the necessity of a thorough education, of a reputable diploma, of affable manners, of regular attention to business, to bills, and the Code of Ethics, but our literature is silent on the subject of signs. Yet their importance in the medical economy is too great to deserve such entire neglect. We know all about gun-shot wounds of the liver, and every doctor in the country who ever had a case has by this time reported it.

Let us turn for a moment, therefore, to a subject of broader and more practical interest; for the doctor's success depends more on his sign than on his diploma, or the Code. It is the link which joins him to the world. Strip the profession of its signs, and it would become an inert mass, an organism with only efferent impulses.

Looking at them from a respiratory point of view, we may consider signs as the oxygen of our medical existence; without them the doctor would shrivel up, like a flower of Paradise in the antiseptic mists of a surgical operation.

But we shall take credit for something more than calling attention to the importance of this subject. It is one worthy of analysis and study. There is much of character in signs. They form the physiognomy which the profession presents to the public. The philosophic student will always learn something of the doctor by examining the silent announcement in gold and black which is offered to the passer-by.

The time is not ripe for an exhaustive classification of signs. It would indeed be disrespectful to a subject of such fundamental importance to attempt a complete dissection of it now. But a Provisional Nomenclature may be useful at this time, and may furnish suggestions to future thinkers.

The medical profession, as it seems to us, proclaims its magnificent and philanthropic potentiality by the Brazen Sign, the Æsthetic Sign, the Tattered Sign, and the Sign of Indifference.

In the first class there is much to suggest remark. The brazen sign is large; it covers the whole doorpost, it stretches from window to window; its lettering is brilliant, and it is set off with scroll-work in the corners; the passer-by sees it, and cannot but

read it; small boys shout out the name as they go by, and adults mutter it over till they reach another block. It is judiciously placed so that the street-lamp illumines it at night. It affects the more public ways, and it indicates the astute and enterprising physician. He is one who maintains a dignified equipoise between the Code which says: "Thou shalt not advertise," and the Bible which says: "Let thy light so shine."

In these days when æstheticism is in the ascendant, when every man of thorough culture lunches at least once a week on the sight of a lily, it would be strange if a love of the beautiful did not affect the style of that corner slab of modern civilization—the subject of this discourse. The Æsthetic Sign, in its supremest development, consists of a black marble slab, in which the physician's name is carved and gilded. When especially "intense," the letters are old Roman, with golden punctuation marks, which delicately suggest to the looker-on that he come to a full stop. Some superficial critics have already classified these evidences of the union of the beautiful with the pilular, as "mortuary signs"—a name which is uncanny and which stamps its user as a Philistine.

We have heard of an enterprising medical student who had a tin sign made for him at the beginning of his studies. This he nailed to the roof of his father's barn, where its brightness was gradually mellowed by sun and snow until the owner graduated. It is those who look far ahead that succeed in this world. And this youth had his reward. He started his career with a tattered sign. Dingy and battered, it assured the reader that that doctor must have prescribed pills for innumerable years.

But the tattered sign is not often produced in this unethical manner. The painful brightness of the first sign as a rule fades but slowly. The painter always puts on a varnish of the first quality. When dimness does come at last, therefore, the pride which is taken in its aged look is quite pardonable. It has been fairly won—and it helps business. For each letter, as it fades into illegibility, proclaims a wider experience. As rust corrupts the metal, the doctor's practice grows. There may be less tin outside, but there is more within. As Diogenes said of dancing: "The worse, the better."

It is only a chosen few who can use that modest and inconspicuous prospectus, which may be called the Sign of Indifference. When the doctor has grown gray in study and hard work, when he has written four books and many monographs, when he owns a share in a medical college, has invented a new speculum, or has been called to treat a President, then he can make his location almost unnoticeable. The young æsthete sometimes aspires to a like disdain of publicity; and transparent glass with slim letters of gold, is all his sensibility will endure. But, as a rule, the transparent sign, the plain silver door-plate, belong only to those whom we have mentioned. It is pleasant to see it. We are assured that here professional advice is really sought for, not offered, even by telegraph.

We have touched but briefly and tentatively upon a subject which we could no longer see so utterly neglected. It is impossible that something further should not be written about it. There are over sixty thousand doctor's signs in this country alone; and every one is different. Yet there is no standard authority which shall tell the young medical graduate with what kind he shall set out on his career of life-long sacrifice.

---

### THE PRESIDENT'S PROGRESS.

THE official bulletins from the White House have continued to be encouraging. There had, at date of writing (August 10th), been no morning when the temperature was not normal or but a degree above it. We are informed, also, that the President has been daily gaining in bodily strength. The only symptoms that could be construed as at all unfavorable have been the somewhat rapid pulse, and an increased amount of fever which set in a week ago.

The pulse on the morning of August 5th had fallen to 88, which was as low as it had ever been. The temperature was normal, and it rose but little in the evening. On the next day, however, the afternoon fever began to increase, so that on Saturday and Sunday the thermometer registered nearly 102° at 7 P.M. This rise was ascribed, by some of the local correspondents, to the intense heat on those days, a heat which the cooling apparatus was powerless to control. The real cause, however, turned out to be another partial obstruction in the course of the wound. The process of granulation partly filled up the orifice, so that the drainage-tube could be passed in only with difficulty. It was evident, also, that the opening had become too small to allow a free exit to the pus. The patient was, therefore, on the 8th inst., etherized. A counter incision was made by Dr. Agnew in the course of the wound and just below the twelfth rib. The operation was plainly a most judicious one. The patient has since then had a little more fever, but the discharge of pus is much facilitated, and the general condition continues good.

It becomes more patent than ever that the President has now only the dangers of a long suppurating tract with which to contend. There seems to be little evidence now that the bullet ever injured the liver, nor is there at present much reason to fear complications from its presence.

In the light of the facts that are furnished the medical and general public, it is not easy to understand the extreme caution of the surgeons as to probing the wound. A new electrical probe which sings out, so to speak, when it touches a bullet, has been provided, but was not used at the time of the operation.

# Reports of Societies.

## NEW YORK SURGICAL SOCIETY.

*Stated Meeting, May* 10, 1881.

DR. H. B. SANDS, PRESIDENT, IN THE CHAIR.

DR. C. T. POORE presented four patients, in illustration of the communication which he made to the society on

### OSTEOTOMY FOR GENU VALGUM.

DR. R. F. WEIR presented a boy upon whom he had performed osteotomy for genu valgum on February 19, 1881, with a satisfactory result. Last week he returned to the hospital with a slight serous effusion into the left knee-joint.

Dr. Weir also presented a patient on whom he had performed

### RESECTION OF THE SUPERIOR MAXILLARY NERVE BEYOND MECKEL'S GANGLION.

The history was furnished by Dr. J. S. Hawley, of the New York Hospital.

F. O——, forty-seven years of age, was admitted to the hospital on Feb. 22, 1881. Patient has suffered from neuralgic pain, affecting right superior maxillary nerve, for twenty-four years. During the last ten years the pain has existed in the parts supplied mainly by the infra-orbital, and, to a less degree, by the inferior maxillary nerves. The pain is spasmodic, coming without periodicity, and lasting from two seconds to a minute. It is also brought on by much talking, reading, or brushing the teeth of the right jaw. The hearing is lost in the right ear. Never has had headache or dizziness.

Patient had a single paroxysm of intermittent fever in 1856. Denies venereal or rheumatic history.

Patient has had medical treatment of the most varied description, without relief—all anti-neuralgic remedies and galvanism having been faithfully tried. The list embraces not only arsenic, quinine, and other remedies of older reputation, but also gelseminum, aconitia, ammonio-sulphate of copper, chloroform hypodermically, and tonga.

Two years ago about one inch of the superior maxillary nerve was removed by Dr. E. C. Seguin, the operation being followed, after two months of constant pain, by partial relief, estimated by patient at fifty per cent. After this time the pain again returned, and the former symptoms are at present existing.

It having been thought that a division of the superior maxillary nerve farther back, if possible, beyond Meckel's ganglion, would offer a reasonable hope of success, on February 23d, Dr. Weir operated as follows, having, previously to the etherization, given a hypodermic of sol. morph. Magend., ℥ ix.

The patient being secured in a semi-recumbent position, a curved incision, two inches long, was made parallel to the inferior margin of the orbit, and three-fourths of an inch below it, being joined at the junction of its inner and middle third by a second incision, two and one-half inches long, directly downward, on a line with the second bicuspid tooth. Both triangular flaps thus formed were dissected back from the bone, and the periosteum raised with an elevator. The antrum was opened by breaking through its anterior wall with a gouge. The infra-orbital foramen was found to be filled with tissue, at first thought to be a reproduced infra-orbital nerve, but attempts to follow it backward, by breaking through the floor of the infra-orbital canal, were futile. The posterior wall of the antrum was broken through at its upper part by means of blunt-pointed scissors, a hook was introduced, and a portion of the nerve, recognized as such by its glistening appearance and striæ, pulled forward. The nerve was separated from its attachments by sliding along it a wire, with a forked extremity, until the instrument met the resistance of bone at the back of the spheno-maxillary fossa. By this means the nerve was also intentionally stretched. The instrument was moved about with the design of loosening or breaking up Meckel's ganglion. Long, curved scissors were then introduced, and the nerve, which was fixed with a pair of fine forceps, cut off close to the foramen rotundum, about three-fourths of an inch being removed. Hemorrhage had been quite free, but was arrested by pressure and torsion.

The edges of incisions were united by means of silk sutures, and a dry compress applied, after the cavity of the antrum had been throughly washed with carbolized water (1 to 20).

One hour after the operation, the axillary temperature fell to 95.4°, and the respirations to eight. A hot-air bath, and atropia gr. 1/8 hypodermically, were administered, and in a few hours both respiration and temperature were normal. It was subsequently learned that the patient was very susceptible to the influence of opium.

There was no return of the pain, with the exception of a small amount in teeth of the lower jaw, and on March 10th the patient was discharged, cured.

*Microscopical examination.*—The portion of nerve removed was examined by Dr. R. W. Amidon, who reported that the fibres from the peripheral end—the stump of the former operation—were swollen, very granular, the myeline much broken up, and showed many empty sheaths of Schwann. The fibres from the centripetal extremity, and from the trunk of the nerve, were some of them normal, but many were like those at the periphery. Connective tissue nearly normal.

DR. POORE then read his paper on

### OSTEOTOMY FOR GENU VALGUM.

(See p. 172.)

DR. WEIR, in discussing the subject, referred to Delore's experience, who had reported four hundred cases in which the success had been very remarkable. His method was to forcibly straighten the limb, tearing through the junction of the epiphyseal cartilage of the femur. He thought the French observers had proven, and it had been proved by Delore's cases, that the ligaments of the joint are not disturbed, and that the separation does take place at the point desired. Similar excellent results had been obtained with more exactness by Collin's apparatus for *redressement forcé*. In the cases in which such results, either by manual or instrumental effort, were obtained, the patients were quite young; but when twelve or fourteen and over, the condition of the parts is very different, and it has been thought to be wisely abandoned as a method of treatment past the ages named. Billroth and Nukerlicz give the results of experiments on the adult cadaver, nineteen to twenty-three years of age, in nineteen cases, and in ten there was rupture of the external lateral ligament. Santi, in twelve experiments made on cadavers, eighteen to twenty-two years of age, ruptured the external lateral ligament nine times.

In living adults or adolescents, in which the operation of forcible straightening had been done, considerable weakness of the joints resulted, which continued for a long period of time.

Returning to the patient presented by him, whose legs had been successfully straightened by the osteotomy, Dr. Weir raised the question: Whether the slight serous synovitis now existing should be attributed to over-exercise—the boy walking about in less than ten weeks, the time assigned by Macewen—or whether it might not be attributed to an accident in the operation (which had occurred, he had understood, with others in the city, without untoward consequences)? In using Dr. Poore's chisel, which was much more slender than Macewen's, he had made, involuntarily, a cross or prying motion, the effect of which was to chip off a small piece of the chisel. The wound healed, however, as promptly as the other. He was inclined to the belief that the synovitis was due to premature and too great use of the limb.

With regard to the more recent question of the suppuration, the experience at present was on the side of antiseptic treatment, that is the majority of cases have been so far conducted under that method, and it has, therefore, not been possible to collect an equal number of cases on the other side. But, as presented, he did not think the report afforded any special encouragement to depart from Macewen's directions. Macewen has performed osteotomy eight hundred times, for different conditions, under Listerism, and has had only *three* deaths, and those were after osteotomy for genu valgum, which he has performed three hundred and sixty-seven times. But in neither of the three cases could the fatal termination be said really to be due to the operation, for one died of pneumonia, one of tubercular meningitis, and one of diphtheria. Dr. Weir's own feeling had been that the use of the spray in this operation could not be dispensed with so safely as in an amputation wound, for instance, where all the parts could be freely bathed with the carbolic solution used.

Dr. Poore thought that the separation in Delore's plan was not confined to the femur. In some cases the epiphysis of the tibia has been separated, and in some the fibula has been torn off.

Dr. Weir mentioned two cases, one of seven years and one of three years of age, in which Delore made the post-mortem, death occurring in one on the second day, and in the other on the thirtieth day, and in both the separation had occurred through the epiphyseal junction, no damage being done to the joint. While regarding with favor Macewen's femoral osteotomy, and rejecting Reeves and Ogston's method, he felt that it was just to give, what the English and American surgeons have not yet done, a fair trial to the milder method of the French surgeons.

Dr. Briddon referred to a case in which synovitis occurred two or three months after the operation, and was the result evidently of passive motion carried to a greater extent than it had been done previously. There remained permanently a certain degree of rigidity. Perhaps too much movement on the part of Dr. Weir's patient gave rise to the synovitis. He also thought that the condition of the limb after osteotomy was very much like that which exists in compound fracture.

Dr. J. C. Hutchison exhibited a set of chisels and a mallet devised by Macewen for performing his operation. He had performed the operation three times, and had followed rigidly the directions which Macewen has given, because he believed that it is only just to the author of an operation to follow his directions strictly. Two of the operations were performed upon the same patient. In consequence of a rise of temperature he removed the plaster-of-Paris dressing from one limb on the third day, and in doing so removed the clot which occupied the surface of the wound, and the wound healed by granulation subsequently. Nothing was found in the wound to account for the elevation of temperature. The opposite limb was not disturbed until the end of four weeks, when the dressings were removed and the wound was found entirely healed.

The dressings were removed from one limb in another case at the end of four weeks, and it not being as straight as he desired, Dr. Hutchison bent it a little and then reapplied the dressings, which remained two weeks before removal, when the patient immediately flexed the knee, on the next day made a few steps, and on the second day walked half way across the ward, which was thirty feet long. No unfavorable symptoms developed in the first case. In both cases fenestra were left in the plaster dressing when it was applied. In the second case, cellular tissue projected from the wound, and it was excised as Macewen directs. In the second case, also, the dressing was removed at the end of twenty-eight days, and the boy flexed the knee at once. He also was taken out of bed the next day, and at the end of six weeks walked very well. In neither of these cases was restraint made after that length of time, and the limbs still remained in the position desired. With the exception of the dressing, he used the full antiseptic treatment. He simply covered the opening with a Lister dressing, and over that placed marine lint. No suppuration occurred in either case.

Dr. Hutchison thought that osteotomy by Macewen's method should not be regarded as parallel with compound fracture, for there is not the same grave disturbance of the soft parts. He also thought it was a simpler operation than fracture with the osteoclast; that the soft parts are much less damaged, etc. As he recalled the reports of the early operations, by forcible separation, not only was the epiphysis of the femur torn off, but that also of the tibia was separated not infrequently, and in adults rupture of the external lateral ligament has occurred, which, as already stated, makes the knee-joint almost useless. He was inclined to regard Macewen's as one of the minor operations in surgery.

In his cases the bones were extremely hard. The deformity originated in rachitis, and the bones were in a condition of eburnation. Dr. Hutchison directed special attention to Macewen's plan of making the cut in the bone, viz.: first, depress the handle of the chisel; then bring it up to a level with the tranverse axis of the bone; and lastly, elevate the handle, thus making with the three movements a fan-shaped opening.

Dr. A. C. Post referred to a case in which, for the correction of bow-leg, he made an incision over the fibula and tibia, divided the bones and applied a felt splint. At the end of three weeks he found that the child had complained of pain, and on examination he found, to his surprise, quite free suppuration on the skin higher up, which had evidently been produced by pressure from the splint. The pus was evacuated by a free incision and the wound soon healed. The bones consolidated without accident. An accident of that kind might lead to the belief that the mischief was greater than it really was.

The President referred to a case in which he performed subcutaneous osteotomy of the femur for

anchylosis of the hip-joint, about ten or twelve years ago, before the days of antiseptics. The operation was that known as Adams', and in the case referred to was a long one, on account of the density of the bone. Only one dressing was applied, and the wound healed without suppuration.

While in Paris, last summer, he had an opportunity to witness the working of Collin's osteoclast in the treatment of genu valgum, and it seemed to him that the instrument worked with admirable precision, and, so far as he could judge, with safety. He saw it used upon two patients; in one, both limbs were operated upon, and in the other, only one.

The apparatus consists of three wooden stocks, which embrace the limb at the middle of the leg, the middle of the thigh, and at the knee, the latter one being movable transversely, and the power applied by means of compound pulleys acting on the end of a long steel lever. The limb is so placed that it is almost impossible for it to rotate, and the force is applied very gradually until a cracking is heard, and then continued until the deformity is over-corrected, when the apparatus is removed. Dr. Sands could not discover any signs of ecchymosis caused by the operation. He also saw two children upon whom the operation had been performed two months previously. In one the result was perfect, in the other it was not, and in that case the operation was repeated. The interne of the hospital where he saw the instrument used had made a special study of the working of Collin's osteoclast, and stated to Dr. Sands that the result obtained from its use was always the same. He also saw the lesion which the instrument produced in the dead-house. Two children were made the subjects of experiment, and in both instances the lesion caused by the osteoclast was found to be the same, namely—partial separation along the epiphyseal line of the condyle of the femur. There was no lesion of the epiphysis of the tibia, and the interne stated that this never happened. It was also found that the separation did not take place along the entire extent of the epiphyseal junction. On the outer side there was slight gaping and the periosteum was ruptured, but there was no rupture of the ligaments, and no rupture of the periosteum on the inner side. It seemed, therefore, that the deformity might be corrected by an insignificant lesion, and if the results were uniform, such as were claimed, the procedure would be preferable to any cutting operation involving the risks attendant upon an open wound.

CLUB-FOOT—NEW METHOD OF OPERATION.

Dr. A. C. Post narrated a case of a child, three months old, that was brought to his clinic, suffering from talipes vaso-equinus, and in which there was a degree of rigidity with which he had not met before. He divided the tendo Achilles and found that but little was gained, and he then determined to operate in the manner preferred by Dr. Phelps, of Chateaugay, N. Y.—that is, by making an open incision across the sole of the foot and dividing all the resisting structures down to the bones. He accordingly made a slightly oblique incision from within outward, and cut every resisting band, and after the operation he was able to bring the foot nearly into its normal position. Lint wet in carbolized water—one to forty—was interposed between the edges of the wound and a bandage applied, without making much effort to rectify the position of the foot. There had been an exceedingly small amount of irritation. Dr. Post was inclined to think that in the class of cases in which there is extreme rigidity, when the result of the ordinary operations or treatment would be somewhat doubtful, that the proposed method of operation would be an advancement.

Dr. Post presented photographs of a patient upon whom Dr. Phelps had operated in the manner described, and the wound healed within three weeks without constitutional disturbance. As illustrated, the deformity was almost completely corrected.

Dr. L. A. Stimson remarked that if the pathological condition in these cases consisted in a defect in the astragulus, he was not able to understand how the operation was calculated to remove it.

Dr. Post said that it did in Dr. Phelps' case; and the degree of success was vastly greater than could be obtained by any other method in the same time.

Dr. Post also presented a

LYMPHATIC GLANDULAR TUMOR,

removed from the axilla of a child three years old. It was extremely deep-seated, and was exceedingly difficult to remove, because of its being wrapped about with blood-vessels. He did not recollect having seen a non-malignant growth in this region the relations of which were so closely united with the blood-vessels as in the present case.

The society then adjourned.

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, May* 19, 1881.

Fordyce Barker, M.D., LL.D., President, in the Chair.

The Librarian acknowledged the receipt of six hundred and ninety-seven bound and seventeen unbound volumes. Of these, five hundred and ninety volumes constituted the medical library of the late Dr. Anthony Gescheidt.

The thanks of the Academy were extended to the family of the deceased.

Dr. F. A. Castle, on behalf of William H. S. Wood, presented a basaltine bust of Dr. John Fothergill, and also, on his own behalf, a portrait of J. Milner Fothergill.

The donors received the thanks of the Academy.

The Corresponding Secretary acknowledged the receipt of a variety of medical certificates from Dr. Ward Francis, of Newport, and, on motion, the thanks of the Academy were extended to Dr. Francis.

The President ackowledged the receipt of checks to the amount of $1,250, to be used in liquidating the outstanding mortgage, and the Treasurer was instructed to transmit the thanks of the Academy to each of the donors.

Dr. E. G. Janeway then read a paper, in which he gave

THE HISTORY OF THE OUTBREAK OF TYPHUS FEVER IN NEW YORK,

so far as information upon the subject had been obtained. As a preliminary step, reference was made to mortality records, and a study of them showed that the existence of typhus in this city in previous years had been greater apparently than in reality. For example, many German physicians wrote upon the death certificate "typhus," without adding abdominalis or some other qualifying word, when death was really caused by typhoid fever. During the years 1878–79–80, returns of death from typhus fever had

been made in only four cases for each of the first two, and three for the last year. There was, however, danger lest a false security be accepted because no known case of importation existed. Dr. Janeway then gave certain details of cases which had a bearing on the question of the

SPONTANEOUS ORIGIN

of the disease. A family of adults living in a tenement-house of the ordinary type were attacked, and the history of the sickness, the character of the eruption, and the autopsy of the mother, proved the disease to be typhus fever. Moreover, although he had cautioned the nurses and the attendants, one of the latter contracted the disease, but recovered. A number of the members of another family were sick, and close inquiry elicited the information that the father had had what was supposed to be pneumonia, but had relapses. In both families the sick occupied inner bedrooms, and the windows were kept closed, through fear of taking cold. A boy in a room above the second family was sick with what an old physician said was old-fashioned "ship fever." Beyond those places it was absolutely impossible to trace the origin of the disease.

In those cases there was a continuous fever, which had all the elements of typhus fever. It attacked adults, was contagious, was communicated to nurses, and at autopsy there was absence of lesions of the bowels.

Dr. Janeway gave an account of the existence of typhus fever in Philadelphia during the last autumn and winter, and also in Camden, N. J., as proved by autopsies made by Dr. Tyson, and examinations made by Dr. Pepper, of Philadelphia.

Statistics concerning the existence of the disease in Dublin, Liverpool, and St. Petersburg, were then read, showing that cases had been in those cities during the last autumn and winter—in the last-named city, ten to thirty deaths occurred weekly, and in Dublin the number of deaths from typhus fever reached ten in some weeks.

Prior to the active outbreak in New York, the disease existed in more than one place in New York; but the outbreak might be said to have begun in the week ending March 19, 1881, in the Shiloh Shelter, and from that lodging-house thirty cases came. Of the first fifty-six cases probably many other physicians could give more or less complete histories of a large number of them.

The first autopsy was made March 19, 1881, on the body of a man who died March 17, 1881, in Bellevue Hospital. There was absence of the lesions belonging to typhoid fever and remittent fever, and the conditions described as present in typhus fever ordinarily existed.

Two hundred and seventy-three cases had been admitted: two hundred and thirty-five males and thirty-eight females. There were sixty-four deaths: fifty-five males and nine females. Under the age of fifteen there were 8 cases and no deaths; between fifteen and twenty, 17 cases and 3 deaths; twenty and twenty-five, 44 cases and 5 deaths; twenty-five and thirty, 48 cases and 6 deaths; thirty and thirty-five, 38 cases and 10 deaths; thirty-five and forty, 41 cases and 9 deaths; forty and forty-five, 28 cases and 10 deaths; forty-five and fifty, 15 cases and 5 deaths; fifty and fifty-five, 13 cases and 4 deaths; fifty-five and sixty, 7 cases and 5 deaths; sixty and sixty-five, 5 cases and 1 death; sixty-five and seventy, 6 cases and 3 deaths; seventy and seventy-five, 2 cases and 2 deaths; seventy-five and eighty, 1 case and 1 death. The cases from Hart's Island, all tramps, showed the greatest percentage of mortality; there were eleven cases and eight deaths.

The disease spread almost entirely by personal contact. There were certain cases which were variations from this general rule. Certain cases were then related which showed that some persons were much more susceptible to the poison than others.

No physician had contracted the disease. Of the orderlies and nurses, eight had contracted it.

The measures adopted to prevent the spread of the disease have been removal of the patients, thorough fumigation of the apartments and burning of the clothing, and subsequent regular inspection of the places from which the patients came.

Dr. Janeway then spoke of the desirability of legal authority to enforce internal quarantine. The treatment had consisted chiefly in administering milk and beef-tea, and using Kibbie's cot or cold sponging, and giving the patients fresh air in tents.

He also spoke of the undesirability of cheap lodging-houses, where the tendency was to take in as large a number as possible. A limit should be placed upon the number who were to occupy one room, and an ordinance had been passed by the Board of Health requiring three hundred cubic feet of air-space for each lodger. There should be a pavilion attached to each hospital, with separate rooms, where cases could be placed to await the development of the disease, or removal.

Dr. Janeway then referred to four cases of

DIPHTHERIA,

the histories of which were so peculiar that he wished to place them on record.

Last autumn he saw in consultation in Brooklyn, in a large, well-ventilated house, open upon all sides, a child sick with diphtheria. The patient died on the following day. Shortly afterward another child sickened with the disease, and also died. Soon afterward the family went to Aiken, S. C., and there all the members took cold, but no diphtheria developed. From there they went to Pilatka, Fla., and shortly after their arrival a trunk was opened and a woolly rabbit taken out and given to the children to play with, and within three days another child sickened with diphtheria, and died at the end of a week. The remaining child was removed to Jacksonville and Sandford, where no diphtheria had existed, but at the end of *five* weeks this child was attacked with the disease, and died.

The PRESIDENT, in bringing the paper before the Academy for discussion, remarked that it was but just to say that one of the medical gentlemen constituting the Health Board had done his duty thoroughly with regard to typhus fever.

DR. AUSTIN FLINT remarked that the facts set forth in Dr. Janeway's paper touched important etiological questions; and, first, whether typhus fever required always a specific cause—or, if you please, a germ—developed in the body of one affected with the disease, or whether its special cause was capable of being produced *de novo* by the occurrence of peculiar conditions at certain times and in certain places.

That was still an open question, and facts could be adduced which sustained an answer given in either the one or the other direction. Many years ago he met with an instance, and reported the same, in a part of the country where typhus fever had never been known to occur, and there were several cases.

Those cases developed in persons living in small rooms, without regard to cleanliness or ventilation, and were typhus fever, as proved by the eruption and autopsical examination; but it was impossible to trace the disease to importation; and yet, perhaps it was the more rational supposition that in some way the germ was received, than that the disease was developed *de novo*. Dr. Janeway has observed analogous instances. But assuming, for the sake of study, that the introduction of a germ was necessary, it had not yet been ascertained how long that germ might retain its vitality. Perhaps it might retain it for years, waiting for the combination of circumstances favoring and necessary to its development. How long could it remain latent and retain its vitality? was an important field for inquiry. Might it or might it not retain its vitality, like seeds which had for scores and hundreds of years remained inactive, and yet developed plants when exposed to the conditions necessary to growth?

Another important point related to exposure to the contagion. Evidently something more than mere exposure was required. There was a vast difference in the susceptibility of different persons to the *contagion* of typhus fever.

With regard to the prevention of the spread of the disease, Dr. Janeway had not presented evidence of the success obtained by the Board of Health in stamping it out; but doubtless that object would be accomplished ultimately. Isolation, cleanliness, disinfection, and ventilation were the powerful means by which this end was to be attained.

In conclusion, Dr. Flint said that he could not refrain from speaking of the noble work done, in years past, by the Health Board of the City of New York. Its labors against cholera, and more recently in stamping out small-pox by isolation, disinfection, and vaccination, were worthy of special and honorable mention.

Dr. Alfred L. Loomis remarked that he had been deeply interested in the history given so carefully by Dr. Janeway, for the reason that it brought to mind his own experience in connection with the outbreak of typhus fever, more severe than the present, which occurred in this city in 1862. At that time he had charge of the fever wards in Bellevue Hospital, and in a single day fourteen patients with typhus fever were brought in from various parts of the city, but the majority of them came from the region of Baxter street. A tour of inspection was immediately begun, and finally he traced the disease to the upper story of a tenement-house in Mulberry street, in the most filthy portion of this city, where a little girl was sick, who sickened on board of a ship that had typhus fever on board, and came from Ireland.

He did not believe that it was necessary, in explanation of a severe outbreak of typhus fever, to trace it directly to importation at the time of the outbreak; but he was convinced, from the history of the disease, so far as the literature was concerned and so far as his own experience extended, that it was a disease which was indigenous to certain localities; that in certain localities it might always be found; and that, when it was developed in localities where it was not indigenous, it was the result of importation, and the same might be said of yellow fever. We did not expect that disease to appear in this city spontaneously, and yet it would spread rapidly here when atmospheric and other conditions were favorable for its spread and development, after it had once been introduced. It was quite probable that typhus fever entered New York oftener than was generally supposed; but, it was necessary that certain conditions be present in order that the poison might become effective in reproducing the disease. He believed that the poison might remain dormant, perhaps for two or three years, and then under favorable conditions develop the disease.

The paper brought up three questions:

*First.*—Was typhus fever ever of spontaneous origin?

*Second.*—Was it ever transmitted from one person to another, except by direct contact?

*Third.*—What were the most certain means of arresting its development and spread?

From Dr. Janeway's history of the present outbreak and spread of the disease, it would seem that most of the cases were the result of direct personal contagion. In no instance has he been able to trace the disease to importation. Indeed, it would be impossible for any observer to trace all cases to their origin. For, as stated in the paper, a large percentage of those attacked by the disease were "tramps," and New York was well adapted to receive "tramps" from all parts of the country, and it was almost next to impossible to trace any disease appearing among them. The difficulties in deciding the question whether or not typhus fever was of spontaneous origin in a large city were almost insurmountable. The cases reported by Dr. Flint were perhaps the strongest on record; and yet, with only a few such cases, we were scarcely justified in regarding the disease as one of spontaneous origin.

With reference to conveying the disease by personal contact or clothing, the following were the facts concerning the outbreak in 1862. No employee in the hospital who was brought in contact with the clothing of fever-patients contracted the disease. Every one whose duty it was to carry the fever-patients from the reception-room to the hospital took the fever. Every physician and nurse who had the care of typhus fever patients contracted the disease; those who were on the surgical side escaped. Every clergyman, with one exception, and he kept at a good distance, who came to administer to the patients in the fever ward, contracted the disease.

Those facts differed from those given by Dr. Janeway in connection with the present outbreak. There must have been a difference either in the intensity of the poison or in the exposure of the individuals. Besides, the less number of cases among the attendants upon the sick, both physicians and nurses, was doubtless due considerably to the fact that medical men know better now than formerly how to care for themselves under such circumstances, with reference to ventilation, etc. No doubt that typhus fever poison might be conveyed by clothing, but, in order that it shall become sufficiently intense to develop the disease, there must be personal contagion or exposure.

Dr. Loomis believed that it was not so much idiosyncrasy that exempted certain persons—except the occasional persons who were apparently exempt from infectious diseases of all kinds—from typhus fever, as it was feebleness of the exposure to which they were subjected. In other words, it was the intensity of the exposure rather than individual idiosyncrasy that regulated the contracting of the disease.

With reference to preventing the spread of typhus fever, he thought that we did not yet know of anything which equalled fresh air in neutralizing the influence of the poison. Its spread could not be prevented by disinfection while persons sick with the disease remained in the building. Thorough quarantine was

necessary, not only of the sick, but of the well, until it was determined whether or not those who had been exposed were to have the fever. To remove the danger from rooms they must be not only disinfected, but exposed fully to the continued influence of fresh air.

Another interesting fact in Dr. Janeway's statistics was the greater rate of mortality among those who had passed the middle period of life.

Dr. John C. Peters said that he had listened to Dr. Janeway with great pleasure, for several very important points had been brought out by his paper. The first was that New York had had more true typhus fever than London, Liverpool, or Dublin; and that it commenced here before it did in Camden or Philadelphia. There was no proof whatever that the disease was imported here, and no death among newly arrived emigrants from it had been discovered. It arose among our own people, and in all probability from our own filth; for New York was very filthy last fall and winter, and was so still this spring, notwithstanding the so-called tremendous effort at street-cleaning which was forced upon the Police Department by the Committee on Hygiene of the County Medical Society, the Society for Sanitary Reform, the mass meetings of citizens and physicians, and the heavy pressure of the whole newspaper press.

The seeds of the disease were sown so widely that the Board of Health was taken by surprise by the sudden explosions of the disease in various quarters, and if it had not been for the active and skilful action of Dr. Janeway, aided by the better street-cleaning forced upon the officials, the almost certain outbreak of a great epidemic would have been witnessed. Some physicians doubt the independent, or *de novo* origin of a contagious disease, but appeal to obscure germs. But typhus fever is a miasmatic contagious disease, arising from a miasm caused by filth, and subsequently becoming contagious.

The more common cause of typhus has been decreed to be overcrowding and bad ventilation; but filth is always an essential factor. Murchison says, p. 115: "Personal squalor and filthy apparel saturated with cutaneous exhalations greatly aggravate the bad effects of overcrowding, and may be necessary for the production of the poison of typhus."

Even the vile lodging-houses, where the disease finally centred itself, and their inmates, were more filthy than usual, owing to the foul condition of the streets and gutters; and the air of these places was more noxious, because the streets around them were filthier than usual, perhaps than ever before.

The poison of typhus fever is more readily discharged than that of any other contagious or eruptive disease. It requires very free ventilation with pure air, and washing of the person and clothing of the patients with clean water. Simple fumigation of apartments destroys the contagion which lingers there. But no pure air or pure water has been obtained in New York for some time past. Two measures seem sufficient to prevent the spread of typhus, viz., the most complete ventilation with pure air, immediate disinfection and cleansing of clothing.

Besides, the sanitary inspection of these lodging-houses must have been very imperfect, for, on the authority of Dr. Buchanan (see Reynolds' "System of Medicine"), the inspection of lodging-houses in London has long been so perfect that few or no cases occur in them. In one great London epidemic only twenty-four cases came from lodging-houses, while great numbers came from the dwellings of the poor. Again, sec. 67, chap. 335, Laws of 1873, says: "The inspector of street-cleaning is required to perform such additional street-cleaning as in the opinion of the Board of Health is necessary to keep the streets, avenues, and public places clean."

But all this is in a manner somewhat compensated for by the activity, courage, and skill of Dr. Janeway when his attention was once aroused.

To return to germs, it is not necessary to seek for them when we have thousands of tons of street, gutter, and privy filth in the front and rear of all the houses in the poorer parts of the city; and decomposing organic matter of the filthiest kind, vegetable and animal, is a far more potent factor in the creation of miasmatic contagious diseases than a few problematical germs. Neither did he believe in occult influences of the atmosphere, except such as are produced by the filthy ground and people all around us. The atmosphere is pure, except for the contaminations which rise into it from the foul swamps, drains, villages, cities, barn-yards, stables, out-door privies, and filthy people and cattle. It is impossible to look at the pure skies above us and have any other rational view. Even sunstroke and cholera infantum are most apt to occur in hot, impure air; and pneumonia and diphtheria in cold, foul air. Filth adds to the severity and frequency also of the purely contagious diseases, and it is purely childish to assume that small-pox, scarlet fever, measles, etc., cannot be rendered more dangerous and even abundant in air which is foul enough to produce true typhus fever, and impress a typhoid character even upon bronchitis, pneumonia, and diphtheria.

Murchison devotes several pages and gives many instances of the spontaneous origin of typhus fever from filth alone. He had expected, as there had been famine and distress in Ireland, followed by great emigration here, that typhus in the shape of ship fever would be brought here. But all the evidence tends to show that it originated here from our own filth, for which the Street-Cleaning Department and the Board of Health are directly responsible.

Dr. Janes answered a question asked by Dr. Peters, by saying that, at the Shiloh Shelter there was a bath-room, a wash-room, and opportunity for washing clothes was provided. The question had been asked, why not close the house as soon as typhus fever appeared there? It was thought, upon the whole, that, if kept open and inspected day and night, in order that cases as they were developed might be taken in charge there rather than be scattered through the city, the spread of the disease would be restricted rather than favored.

Dr. Gouverneur M. Smith thought it accepted that atmospherical conditions, perhaps not yet fully understood, favored the development of various diseases, especially of the variety under discussion.

Dr. Janeway thought that one reason, aside from a certain amount of idiosyncrasy, why physicians in the present outbreak had not been attacked by typhus fever, was that they were in better hygienic and physical condition than had been the case in many epidemics, and he also believed that men were less liable to the disease than women. In answer to a question asked by the President, he said that none of the patients in the Maternity Hospital had had the fever.

With reference to the influence of dirty streets, he did not believe that contagious diseases were spread in any great measure by them. Cleanliness does something toward eradicating typhus fever.

The President referred to two cases under his own

observation, in which it was evident that the clothing contained the poison of typhus fever and gave rise to the disease. A gentleman had typhus fever severely. A woman who washed his clothes contracted the disease and died. No person in attendance upon the patient contracted the disease. The husband of the woman and his sister took the disease and recovered.

The other instance was similar, and cases of that character proved that the disease might be propagated by clothing.

Dr. Charles Carroll Lee referred to the one thousand ovariotomies performed by Mr. T. Spencer Wells, with seven hundred and sixty-nine recoveries, unprecedented in number; also to the fact that the illustrious surgeon is a foreign member of the New York Academy of Medicine, and his marble bust adorns its hall, and offered the following resolutions, which were seconded by Dr. A. C. Post and unanimously adopted:

*Resolved*, That the congratulations of the New York Academy of Medicine be transmitted to Mr. T. Spencer Wells, a foreign Fellow of this society, for his remarkable and unprecedented achievement of one thousand ovariotomies, by which the lives of seven hundred and sixty-nine women have been saved.

*Resolved*, That a copy of these resolutions, properly authenticated by the President and the Secretary, be forwarded to Mr. Wells.

The Academy then adjourned.

## Correspondence.

### TREATMENT OF STRICTURE OF THE STOMACH.

To the Editor of The Medical Record.

Dear Sir—The following cases of interest to the profession were reported to the Minnesota State Medical Society, a copy of which I herewith transmit for publication if you deem it sufficiently worthy.

Case I.—About March 15, 1880, I was invited by Dr. A. W. D—— to see a patient (aged about one year) who was suffering from stricture of the œsophagus, low down, caused by swallowing concentrated lye five months previous. She was unable to take any nourishment per mouth, and was sustained by nutrient enemata. We attempted to pass a No. 8* urethral bougie, but failed. We then gave ether, with no better success. Five or six days afterward I was requested to take charge of the case and attempt dilatation. This I reluctantly consented to do, having no hope whatever of success. At the first sitting I succeeded, after some effort, in passing the stricture with a No. 5 urethral bougie, and followed it in a few minutes with No. 6. On the following day I succeeded in passing Nos. 6 and 7, and each succeeding day a larger size, until I was able to pass No. 10. At my second passage of No. 10 a too rapid and forcible removal of the bougie occurred in the hands of another, whom I allowed to remove it, to show how firmly it was held by the stricture. As a consequence, the next attempt at introduction of the bougie was followed by the appearance of blood, and succeeding attempts by blood and pus, so that I was compelled to suspend operations for several days. The parts gradually healed, however, and in the course of a week or ten days I was again able to pass a small bougie; but it was not until May 19th—two months after commencing treatment—that I was able again to use even a No. 9 bougie. I then taught the mother how to pass them, and resigned this part of the treatment into her hands. By July 18th she had increased the size to No. 11, by October 28th to No. 13, and by February, 1881, to No. 14, which she is still using, I being as yet unable to get bougies of larger size that are of any use. The bougies that have served me best are the ordinary elastic hollow urethral bougies, stiff and hard with age, easily softened by warming, but retaining firmness and elasticity, and, if they become too limber with use, permitting the introduction of a smaller one within. The solid conical bougies have not served me well, being so limber after once or twice using as to double in the back of the pharynx and allow no pressure to be exerted on their point.

The patient at present has every appearance of perfect health; is able to eat, with careful mastication, all kinds of food, and there seems every reason to anticipate for her an ultimate complete recovery.

Case II.—About the time of my undertaking the treatment of the above case, the following similar one came to my knowledge, and served as a stimulus to persevere in my treatment. The subjoined history was obtained in substance by correspondence with the parents of the child. L. M. C——, aged six years, when sixteen months of age swallowed concentrated lye, and after a time it was noticed that she had some difficulty in swallowing, and finally was unable to take even liquid into her stomach. Her parents "consulted head doctors of medical schools" by the advice of their physician, and each pronounced her case a hopeless one. The physicians attempted to pass "tubes into her stomach, but failed, and said she must die." The father then procured a set of bougies and attempted to pass them himself, and succeeded in passing one the "size of a knitting-needle." Sometimes he was unable to pass this for days at a time, at other times it would be an hour before he was able to pass the strictured portion. He learned of the exact position and shape of the stricture by getting her to swallow milk, and immediately after vinegar, which formed a curd; he then playfully threw her over his shoulder, with head down, when she immediately coughed up this curd, a perfect cast of that part of the œsophagus immediately above the stricture, showing him a deep pocket with the stricture on one side, and its opening about the size of a pin. This knowledge enabled him to manipulate the bougie so as to enter the stricture more readily. After passing the bougie a few times she was able to take liquid nourishment, and they then would not pass it again until she "choked up." After a time, however, they passed it more regularly, and for a period of three years, up to the fall of 1879, when they abandoned the tube, never having been able to use a larger than No. 8. This patient is reported able to eat all kinds of food, and is considered to be in perfect health by her parents. These two cases certainly illustrate what may be accomplished by courage and perseverance in the use of the dilator. In my researches after successful cases of treatment by this method, I find but one other. See "Cohen on Diseases of the Throat," fol. 296. I would be glad to learn of others, if there are any.

Respectfully yours,

J. Henry James, M.D.

St. Peter, Minn.

* Sizes designated herein are according to the American scale.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 24, 1881, to August 6, 1881.*

ALEXANDER, CHAS. T., Major and Surgeon. Granted leave of absence for fifteen days, from 19th inst. S. O. 98, Department of West Point, July 15, 1881.

GARDNER, EDWIN F., First Lieut. and Asst. Surgeon. Relieved from duty in Department of Dakota, to proceed to Eastport, Me., and on arrival there report by letter to the Surgeon-General. S. O. 171, C. S., A. G. O.

HUBBARD, VAN BUREN, Capt. and Asst. Surgeon. Granted leave of absence for four months. S. O. 169, A. G. O., July 26, 1881.

KING, WILLIAM H., Capt. and Asst. Surgeon. Now awaiting orders at Greencastle, Pa., to report in person to Commanding General, Department of the East, for assignment to temporary duty. S. O. 171, A. G. O., July 28, 1881.

TORNEY, GEORGE H., Capt. and Asst. Surgeon. The leave of absence granted him from Headquarters, Department of the Missouri, June 21, 1881, extended one month. S. O. 76, Military Division of the Missouri, July 25, 1881.

GARDNER, EDWIN F., First Lieut. and Asst. Surgeon. The operation of Par. 3, S. O. 171, C. S., A. G. O., in his case, suspended one month. S. O. 177, A. G. O., August 4, 1881.

## Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending August 6, 1881.

| Week Ending | Typhus Fever. | Typhoid Fever. | Scarlet Fever. | Cerebro-spinal Meningitis. | Measles. | Diphtheria. | Small-pox | Yellow Fever. |
|---|---|---|---|---|---|---|---|---|
| July 31, 1881. | 10 | 19 | 100 | 4 | 44 | 100 | 9 | 0 |
| Aug. 6, 1881. | 2 | 8 | 93 | 7 | 28 | 113 | 27 | 0 |

SUBPERIOSTEAL EXCISION OF ULNA.—Dr. M. Kennedy, of Sherman, Texas, reports the case of a lad aged eleven years, who suffered from chronic ostitis of the ulna, the result of an injury three years previously. Dr. Kennedy performed the operation of subperiosteal excision, June 25, 1881, with good results. The parts healed kindly, and bone is now being reproduced at the upper and lower portions of the periosteal sac. Passive motion at the elbow was resorted to early, and the functions of the elbow, forearm, and wrist are well preserved.

INSANITY AS A PREVENTIVE OF MALARIA.—Dr. John M. Ward, Superintendent of the New Jersey State Lunatic Asylum, comments upon the curious fact that, notwithstanding the great prevalence of malarial and intermittent fevers, in the section of the country where the asylum is located, not a single case of malaria has appeared among the patients in the institution, who numbered last year 672. Several attendants and laborers were attacked with the disease, but not one lunatic. The explanation offered is, not that insanity is a protection against malaria, but that the insane patients are never allowed out of doors after nightfall. It may be that the malaria is not recognized.

THE DEATH OF PROFESSOR MAURICE RAYNAUD, which took place suddenly on the 30th of June, from angina pectoris, will be a matter of great regret to those interested in the International Medical Congress. Professor Raynaud was to have delivered the address in medicine, and had chosen for his subject "Scepticism in Medicine, Past and Present."

VACCINATION AMONG THE MOHAMMEDANS.—The wife of the Shereef of Morocco has, it is reported, succeeded in inducing the Moors to accept vaccination. The Shereefa, as she is called, performs the operation herself, and sometimes vaccinates as many as fifty a day. She is an Englishwoman, and retains her Christian faith.

THE DEATH OF M. CHANTREUIL, an accomplished obstetrician, took place recently. He was just engaged, in connection with M. Tarnier, in writing an extensive treatise on obstetrical science and practice.

SIR JAMES PAGET has been re-elected member of the council of the Royal College of Surgeons, England. Messrs. J. W. Hulke and C. Heath were also elected members.

THE REPORT ON VIVISECTION in England during the past year shows that three hundred and eleven experiments were made. Of these only thirty can be presumed to have caused any special pain. These were cases in which diseases were inoculated, the animals dying from the effects. Most of the other cases were simple inoculations, or were experiments performed on anæsthetized animals.

LEPROSY COMMUNICATED BY VACCINATION.—Small-pox at Honolulu is said to be decreasing. During the four months ending June 4th, there were seven hundred and sixty-four cases, of which thirty-six per cent. ended fatally. The Board of Health enforced a strict quarantine, and thus prevented the infection from spreading to the other islands. Unfortunately bovine virus was scarce, and hence vaccination could not be uniformly enforced, the Board having forbidden the use of human virus, through fear of communicating other diseases. On this point the opinion of Mr. Carter, president of the Board, is significant and, indeed, startling, if he has an adequate basis for his conclusions. It is his belief that of nearly eight hundred lepers sent to the leper settlement subsequent to the last small-pox epidemic, probably six hundred became thus diseased through vaccination with human virus. During the prevalence of the scourge, which has just subsided, strong complaints were made that the Chinese concealed cases of the disease until they became hopeless, and then turned them over to the Board of Health in order to escape the cost of burial and any unpleasant complications which might otherwise have arisen from the discovery of a corpse.

INVESTIGATING THE HEALTH OFFICER OF THE PORT OF NEW YORK.—The following resolution has been adopted by the State Legislature.

*Whereas*, It is alleged that the fees of the Health Officer of the Port of New York are exorbitant; that they aggregate $75,000 annually, and that a proper and searching investigation into the man-

agement of the department of the Health Officer of the Quarantine establishment will result in a great saving to the people; therefore

*Resolved*, That a special committee of five be appointed to investigate and ascertain the emoluments, and to examine into the administration of the Health Officer of the Port of New York, with a view of making the Quarantine Department self-sustaining, and passing such laws as may be in the public interest; and that said committee be authorized to sit during the recess of the Legislature and have power to send for persons and papers.

Dr. Smith was interviewed on the above subject by a reporter on the *Times*. It came out that the fees were less than $100,000 yearly, but how much less were not told. The monthly expenses, according to Dr. Smith, are $3,000. It appears also that a pilot at Quarantine receives $90 a month, an assistant physician $50 a month, and a fireman $40 a month. So, judging the capabilities of those employes by their salaries, a man sick on shipboard does about as well to get a prescription from the Quarantine fireman as from a Quarantine physician, and he is in rare luck if he can be attended by the pilot.

Dr. James D. Fitch, whose figure was a familiar one in the medical practice twenty years ago, died suddenly on July 20th, at his residence in this city, in the eightieth year of his age. Dr. Fitch was contemporary in medical practice in this city with the last generation of medical men, such as the late Dr. Budd, Dr. J. N. Francis, most of whom he outlived by many years. He retired from professional life some years ago, and passed the last decade of his existence in the quiet seclusion of his home, having amassed a competence by professional work. Of late years he was seldom seen at the meetings of medical societies and infrequently in general society, age having impaired his zest for scientific discussion and diminished his interest in medical topics.

New York Physicians at the International Medical Congress.—The city of New York seems likely to be well represented at the coming International Congress, and most of the visitors will read papers before the various sections. Drs. Fordyce Barker, Austin Flint, John G. Adams, E. C. Harwood, T. E. Satterthwaite, James R. Little, R. C. M. Page, Gabriel Grant, A. S. Purdy, Newton M. Schaffer, Louis L. Seaman, George M. Beard, H. S. Oppenheimer, G. W. S. Arnold, James R. Taylor, H. B. Sands, Paul F. Mundé, Edward Bradley, F. H. Bosworth, are among those who have sailed. Dr. Satterthwaite, we are informed, reads a paper before the Pathological Section, and will inform the Britishers as to what America has been doing in pathology. Dr. Bosworth has a paper on Operations on the Nasal Cavity. Dr. Beard presents the subject of Trance and Allied Nervous Conditions. Dr. Flint, Dr. Arnold, and Dr. Sands, are also said to have papers.

A State Investigation of Adulterations in Food.—Under the law recently enacted by the New York State Legislature, the State Board of Health were authorized to investigate the subject of adulterations in food, and they have already begun work. Inspectors have been appointed to collect and analyze samples of butter, beer, baking powders, bakers' chemicals, cocoa, cordials, canned food, confections, cereals, cheese, meat extracts, fish and fish extracts, fruit essences, ether, gelatine, honey, ice-cream, milk, molasses, lard-oil, olive-oil, quinine, sugar, syrups, soda-water, spices, spirits, tea, wine, and all pharmaceutical preparations.

It will be remembered that partial investigation of this kind was made some time ago by our City Board of Health. They found that in the case of sugar of one hundred and nine samples, forty-five only were thoroughly pure and good; fifty-one, however, contained only accidental dust, while eight were marked dirty, and five were dirty. Still, in no case was there any intentional adulteration, and all the samples were free from glucose, which substance is now largely introduced.

It is not likely that much which is really injurious will be found, though adulterations may be numerous enough. Still, in the matter of teas, coffee, spices, condiments, confectionery, and diseased or putrid meats, there is no doubt room for plenty of investigations.

Griscom's Fast.—At the beginning of the fast the experimenter weighed 197¾ pounds. At the end of the seventh day he weighed 179 lbs., loss, 18¾; thirteenth day he weighed 178¼ lbs., loss, 19¼; twenty-first day he weighed 168¼ lbs., loss, 29¼; thirty-first day he weighed 163 lbs., loss, 34¾; fortieth day he weighed 151¼ lbs., loss, 46¼. His abdomen, thigh, calf, arm, and forearm were measured on the first day of the fast, and on Sunday, the forty-second day. The measurements were as follows:

| | First Day. | Forty-second Day. |
|---|---|---|
| Abdomen | 43¾ | 30 |
| Thigh | 21 | 17⅛ |
| Calf | 16 | 12⅜ |
| Arm | 12⅛ | 10⅛ |
| Forearm | 11⅛ | 9⅜ |

No marked changes are given regarding the pulse, temperature, and respiration. He drank from twenty-four to forty-eight ounces of water per day. His strength continued till the end, and he often walked considerable distances during the last part of the fast.

He is said to have been watched by several reputable physicians, including Dr. Raines, one of the faculty of Rush Medical College.

Doctors Wanted.—On the Shetland Islands, says the *British Medical Journal*, there are, excluding the burgh of Lerwick, only six doctors to administer to the wants of a population of twenty-seven thousand.

Dr. F. R. S. Drake has been appointed clinical professor of practical medicine in the University Medical College in this city.

Medical Literature.—The *Philadelphia Medical Times* comments upon the growth of medical literature so-called. It says: "Using the *Index Medicus* as a guide, we find that in the world last year eleven thousand seven hundred doctors thought they had something new to say, or some new way of saying something old. Mostly they were moved by vanity, and surely the outcome is vexation of spirit."

Electrical Probes and Forceps.—The subject of gun-shot wounds and all that pertains to them is now exciting much attention. A new probe and forceps just devised by M. Trouvé comes in quite apropos, and is an instrument likely to be of great use occasionally, if it does what is claimed. It consists of two metal stems placed side by side, but separated by an insulator, and terminated by two very fine sharp points. Conducting wires are connected to the butt end of these two blades, and include in their circuit a small inverting battery and a tiny trembler bell. When the probe comes in contact with a metallic body in the wound, say a ball or spark of

metal, the circuit is completed across its points and the bell is rung, thereby announcing contact to the operator. The conductivity of bone, wood, or flesh, is too feeble to make the bell ring; but a fragment of metal serves at once to do so. Lead can be distinguished by the continuous ringing which it gives, owing to the penetration of the points into its mass; while iron or copper gives a jerky sound, and the approach of a light astatic magnet, suspended by a wire without torsion, will enable the surgeon to tell iron from copper.

The same arrangement has been applied by M. Trouvé to surgical forceps for extracting foreign bodies out of wounds, and the surgeon is informed by the trembler that he holds the body in their grasp. A recent notable case of extracting a steel spark from the eye of a Berlin workman by means of electro-magnetism deserves mention. The eye had become very much inflamed, and it was necessary either to extract the mote without delay, or remove the eye itself. Dr. Hirschberg, a Berlin oculist, succeeded in the former plan by inserting a soft iron probe into the eye until it touched the mote, and then, by magnetizing the probe with the help of an electro-magnetic coil, he was able to draw the dangerous intruder forth.

The Location of the Bullet in the President's Wound.—Dr. Bliss communicates the following as the most probable view of the course of the bullet:

He thought that it struck and broke the tenth rib and passed through it, cutting a hole through the wall of the great cavity. It bruised the liver, but whether or not it had broken through the covering of the liver, he did not feel entirely certain. He thought the ball had struck the edge of the diaphragm. The rib had turned the ball downward, and it had passed back from the cavity into the anterior wall of the abdomen. The short track of the wound along the inner wall of the cavity had been entirely covered by the adhesive inflammation, so that there was no escape of pus into the great cavity, but a channel from the ball to the outer openings of the wound.

Leprosy in California.—In reply to a letter from Dr. J. Nevens Hyde, asking information regarding leprosy in California, Dr. J. W. Foye, physician to the small-pox hospital and lazar house in San Francisco, has sent a very interesting history of the disease as it has occurred in his State. He says: "In regard to the subject of your inquiry, leprosy, I shall be but too happy to furnish you with all the data attainable from our records; at the same time would remind you of the fact that the subjects of the disease, with one exception, have been Mongolians, and unable to give other than the most meagre account of themselves, and we are often compelled to rely upon conjecture in fixing the age of the patient. I find by reference to the record that the first leper, Hoy Tong, was admitted July 5, 1871, and that he died on the 29th of September, 1875. Since that date fifty-one additional cases have been received—forty-eight males and three females—making a total of fifty-two cases to account for. The hospital was designed for the treatment of small-pox exclusively, and the leprosic have been admitted only when found necessary to relieve other public institutions, or perhaps the streets, of their presence. Three invoices, aggregating forty-five, have been sent by the authorities to China. Three have died of the disease, and one from accidental causes, and one escaped. One committed suicide, and one, a Caucasian, is still an inmate. The ages of the patients have been: between fifteen and twenty, 4; between twenty and twenty-five, 9; between twenty-five and thirty, 17; between thirty and forty, 13; between forty and fifty, 9.

"No record has been kept of the duration of the disease at the date of admission, nor of the length of time the patient had been in the country, an omission much to be regretted, and doubtless due to the fact that their detention here was but temporary and pending shipment. It is not an assumption to say they were, to appearance, healthy when they entered the port, the Chinese Six Companies being too keenly awake to their own interest in importing unproductive labor, but that they were the subjects of the disease in its incubation stage, as the date of shipment is an inference irresistible. The type of the disease is anæsthetic, tubercular, mixed, not given."

Regarding treatment, he says: "For the past two years alimentation has been our only treatment. The leper requires good nutrition, and wants it often. The ration of the American army is insufficient for his support until the last stage of the disease has been reached.

"Any opinion as to the number now in the city would be mere conjecture. I have seen none out of the Chinese quarter. It is less general than is commonly believed; yet the fact is a significant one that, on the 2d of June every known leper in the city was shipped for China, and before the end of the year fourteen new cases have accumulated upon our hands. The Chinese consul claims hospital rights for these people; the authorities resist the claim, and the courts are now adjudicating the question—Is it contagious? English writers in India say it is not, in the sense in which the term is usually employed, but the Chinaman, who has been familiar with the disease and its traditions for centuries, avoids the leper with great care, and will stand for hours rather than occupy a seat that had been vacated by one.

"The leper maintains the most profound silence upon the subject of heredity. I have seen but one who admitted its existence as a family taint, and he would, it is probable, have denied it had not the inquiry been made prior to a conference with his fellows in the lazarette."

National Dental Association.—The second annual meeting of the National Dental Association was held in this city, August 9th and 10th. President Northrop, of New York, in the chair. There were about thirty members in attendance. Dr. F. M. Odell read a paper on "Lithiasis," and Dr. M. L. Rhein followed with one on "Dental Education." These papers were then discussed by the members generally. On the second day the following officers were elected for the ensuing year: President, John B. Rich, of this city; vice-presidents, J. B. Patrick, of Charleston, S. C., J. H. Smith, of New Haven, Conn., D. W. H. Dwenelle, of this city, J. R. Walker, of New Orleans, F. A. Levy, of Orange, N. J.; assistant secretary, F. M. Odell; assistant treasurer, John Allen, of this city.

Dr. Patrick, of Charleston, read a paper concerning a peculiar case of interstitial growth of a tooth. The paper was then discussed by Drs. Abbott, Walker, Patrick, Buckingham, and Odell. A paper read by Dr. Walker, of New Orleans, on "Tooth Culture," was discussed by Drs. Dwinelle, Allen, Abbott, Patrick, Hunt, Ambler, Winecler, and Swift. The association then adjourned until August, 1882, when it will meet in Washington.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 20, 1881.

## THE INTERNATIONAL MEDICAL CONGRESS.

The recent Medical Congress in London was the largest and most important one which has yet been held. This was anticipated by the elaborate arrangements of the Executive Committee, by the interest which it developed in the subjects to be discussed, and by the pains which it took to secure the attendance of the representative medical men of different countries. The cosmopolitan character of the assemblage was particularly marked, leading men from every civilized country being present and taking part in the discussion of the subjects in which they were most interested, and concerning which, in most cases, they could speak with authority. Too much credit cannot be given to the Committee of Arrangements for the admirably systematic manner in which they disposed of the vast amount of material placed in their hands. Although there was occasionally some interruption in the exact order of exercises, arising from peculiar exigencies, it is somewhat remarkable that these were not more frequent in occurrence, and, as regards the systematic workings of the sections, more serious in their results. We venture to say that in the history of medicine no approach has been made to the successful accomplishment of so much important scientific work equal to that of the International Medical Congress in London. That great city, one of the medical centres of the world, offered its almost unbounded medical resources to the foreigners, each corporation vieing with the other in the effort to make the visit on the part of the large delegation one of interest and profit.

The address of the President, Sir James Paget, was a model of its kind, and was in every way appropriate to the occasion. This is high praise, it is true, but it is well substantiated by the classic and dignified manner in which he handled his subject, and by the breadth of view which he offered of the field which each and all of his hearers had so variously and yet so successfully cultivated. There was a desire on the part of the orator to deal with the general and fundamental principles that underlie true scientific progress in medicine, rather than discuss abstract questions with which but comparatively few of his auditors could agree; to discuss the purposes and practical aims of a large assemblage of trained minds in contrast with individual effort, however successful; the weighing of facts from the standpoints of different observers, and the interpretation of their true significance by the accumulation of apparently conflicting testimony.

With these ends in view, he truthfully and forcibly maintained that the best work of the Congress should be in the direction of clearing and strengthening our knowledge of facts and our correct appreciation of proved scientific realities; in bringing all its force of numbers and varieties of intellect "to press forward the demonstration and diffusion of truth as nearly to completion as may from year to year be possible."

It is just to say that the work of the last Congress has fairly fulfilled its function as had been prospected by its distinguished President. This result has been, as previously intimated, in no small part due to the practical character of the subjects selected for discussion and to the judicious disposal of the same among the members. The desire was to get at facts rather than theories, and to select the subjects accordingly. In all the sections the discussions were on definite questions of present and practical interest, and the introductories of the presidents of the various sections for the most part gave them in a general mention due importance. With scarcely an exception, the addresses of the chairmen of Sections were well-timed, practical, and interesting. In a few instances these efforts bore evidences of most profound study and more than ordinarily careful preparation, which is saying a great deal, considering the average excellence of the others.

As might have been expected, the address of Prof. Virchow was well appreciated by the Congress. Touching, as it did, upon a subject of vital interest to the progress of scientific research, the sentiments which it contained and the views it advanced very properly received the hearty endorsement of his peers. The distinguished orator very wisely said that if, as scientists, we could not prove our just right before the world for the extension of pathological experiment, and on the strength of that right agree among ourselves, our cause must, from the beginning, be regarded as lost. The value of these methods of investigation were demonstrated with the clearness of one having settled convictions, and with the earnestness of one who had the necessary

data of proof at command. Prof. Virchow, in the preceding Congress, appeared as the able defender of vivisection as an efficient and necessary aid to scientific progress, and his recent effort may be viewed as a fitting continuation of his argument in a more advanced direction as applied to other fields of inquiry. Although on some points his opinion regarding the possibilities of advance may be extreme, the profession, as a whole, will be ready to endorse his present view of the general situation, and will receive his recommendations with becoming respect.

It was eminently fitting, considering the purposes of the Congress, its representative character, and the high scientific standing of its members, that it should be under royal patronage. The formal opening of the Congress by the Prince of Wales was a becoming and respectful recognition on the part of the government of the value of scientific medicine, and was, in such a spirit, appreciated by all present. But the good effects of this patronage by royalty was offset in no small degree by the conditional non-recognition by the Congress of female doctors. It may not be generally known that forty-three properly qualified female physicians were denied admission to the Conference simply because they were women, and because their presence at the Conference would meet with the stern disapproval of the Queen. It will be quite evident, whatever may be the opinion regarding the study of medicine by women, that Queen Victoria, both as a sovereign and woman, committed a grave error, and for which there does not appear to be any reasonable explanation. The right of women to study medicine can never be decided by royal decree, nor by the personal prejudices of even a queen. Much less by such means must their liberties be jeopardized, or their privileges of representation be denied in any scientific body of which they may be qualified members. The British managers of the Congress doubtless gained much by the patronage of their sovereign, but from a scientific standpoint the medical world will not endorse its action, and will justly condemn a course illiberal in spirit, obnoxious in principle, and dangerous in precedent. In the strictly American sense of fair play to women, the Queen should be the last person to oppose any obstacle to their possible advancement. It is perhaps a trifle disrespectful to Her Majesty to say that on a question of principle she exceeded her true prerogative. Not only was she incompetent to decide the question, but she seemed incapable of understanding that the Congress was an international and not a British one, and that the intrusion of her preferences under the conditions named was, to say the least, an act of great discourtesy to the foreign members. But, unfortunately perhaps for herself, the Queen has not yet settled the question of women doctors. On the contrary, she has erected a royal altar for a long-coveted martyrdom of her presumably misguided and presumptuously wilful sisters.

Considering the immensity and variety of the material, it will not be wondered at if some items of the elaborate programme were unavoidably omitted, that many papers were not presented, that the discussions in many instances exceeded the limits of the time allotted, while there was no opportunity for others advertised. But all this must be acknowledged to be inseparable from conditions which could not be anticipated, or circumstances which could not be controlled. The great matter for amazement is that so much work should have been compressed into so few days, and the main objects of the meeting so satisfactorily fulfilled.

In the present issue we publish a full account of such proceedings received from London up to the time of going to press. We have taken great pains and have gone to much expense to secure from correspondents in that city a special report of the proceedings for the MEDICAL RECORD, and it is to be hoped that our efforts will be repaid by entire satisfaction to our readers. Thus far, although from direct and authoritative sources we are enabled to give a good idea of the work done in the general sessions and in the meetings of the sections, we are compelled to defer the publication of the detailed reports until our next issue. On the appearance of these publications we shall take occasion to offer such additional comments as may seem to be necessary. The addresses delivered at the opening session, and the principal ones before the sections, are given in their appropriate places in this issue, and will serve to indicate the plan of work pursued and the value of the material yet to come.

---

### THE UTILITY OF THE UNITED STATES MARINE HOSPITAL SERVICE.

WE have received a somewhat curious document, which purports to be a Report of the Committee of the Medical Society of the State of California on the Relations of the Marine Hospital Service of the United States to the Commerce, the Public, and the Medical Profession. This report is signed by three medical gentlemen, the first being an ex-member of the service, who retired somewhat over a year ago.

The contents of the document betray a very strong effort to make out a case against the Marine Hospital Service. It contains assertions and implications which are totally at variance with our knowledge of the workings of this important service. It is charged that the service is a charity, that it is injurious to the sailor morally, is a burden on the Government and on its beneficiaries, with whom it is unpopular, and for whose needs it is inadequate. These are the principal charges which are made. So far as any evidence that we can find goes, all these charges are essentially untrue. As they are only assertions and

are not supported by testimony of any kind, it is hardly necessary to say anything more. We have referred before, at various times, to the work of the Marine Hospital Service, and have thought it but just to call attention to the progress which the conscientious labors of its officers were making in its efficiency. It is virtually a vast provident medical association, which compels to prudence a class of men who incline to it least and need it most. It is also an organization from whose work much that is of value to medical science may be justly expected.

There is no need to go into any special defence of it, however, since it is doing a work whose usefulness cannot be seriously questioned.

---

PRESIDENT GARFIELD.

SINCE our last report the President has suffered from a slight febrile movement during each afternoon. The temperature at such times has ranged from 98.6 to 101.5, and the pulse from 100 to 108. The wound has presented a favorable appearance, giving exit to a free discharge of laudable pus, and the healing process appears to have been progressing favorably. The latest report was to the effect that the entire tract of the bullet had nearly healed, and that granulations had approached to within three inches of the mouth of the last incision. The general condition of the patient, as previously mentioned, was maintained until the night of August 14th, when the stomach showed signs of marked irritability, attended with frequent vomiting and consequent prostration. At 8 A.M., August 15th, the pulse was 108; temperature, 100.2° F., and respiration, 20. During the morning a slight amount of nourishment, consisting of milk and meat-extract, was taken and retained. The discharge of pus was free and of good character. At 12.30 P.M., August 15th, the pulse was 118; temperature, 99° F., and respiration, 19. From this time until 6.30 P.M. the patient was tormented with nausea and vomited three times. In the meanwhile the pulse had risen to 130, the respiration to 32, while the temperature remained about the same, 99.6° F.

These symptoms were attended with those of alarming prostration, and the case assumed a very critical aspect. The prostration and nausea continued during the night, and vomiting occurred several times.

August 16th, 8 A.M., the pulse was given as 110; temperature, 98.6°, and respiration, 18. The stomach still being irritable, and the patient continuing in a greatly prostrated condition, nutritious enemata were administered. At noon the pulse was slightly increased in frequency, and had lost somewhat of its force. It was reported at 114, with temperature at 98.3°, and respiration 18. During the afternoon the patient did not show much signs of rallying, although he vomited but once. Pulse, 120; temperature, 98.9°; respiration, 19.

August 17th, 8.30 A.M., it is stated in the official bulletin that the patient passed a tranquil night, without vomiting. The pulse is reported as 110; temperature, 98.3°; and respiration, 18.

At the present writing the gravest anxiety exists regarding the issue. At best, the condition is exceedingly critical, and gives rise to the possibility of a speedily fatal issue unless the patient quickly rallies. The unfavorable turn is, no doubt, due to the long-continued weakness of the patient. This is certainly the worst phase that the case could assume at the present time. In fact, it would be difficult to name a more dangerous complication under the present circumstances, or one capable of bringing about more immediately serious consequences. From all accounts the state of the wound has nothing to do, except in a very indirect way, with the patient's prostrated condition; nor does it appear that there are any symptoms of septicæmia or of pyæmia, save such as have existed in the imaginations of those who have not had an opportunity of seeing the case or of weighing the significance of the symptoms at the bedside. Whatever may be the result of the case, it is due to the gentlemen in charge to say that the treatment has been skilful from the start, and that every means have been used to mitigate the sufferings of the patient, and to ward off every possible danger from all threatened complications.

As might have been expected, the management of the case has been open to much criticism by the secular press. It is to the credit of the profession, and especially of the gentlemen in charge of the case, that so little can be said concerning what might have been done and what was not done. Despite the journalistic prescribers in some of our leading dailies, the people have continued to maintain a confidence in the attending and consulting surgeons which is as gratifying as it is necessary. There seems, very justly, to be but one sentiment entertained both by the profession and the public regarding the judicious manner in which this case has been treated from the beginning.

---

HINTS FROM THE HOMŒOPATHIC PHARMACOPŒIA.—Dr. Piffard, in his treatise on "The Materia Medica and Therapeutics of the Skin," gives a number of remedies not confined to the U. S. Pharmacopœia.

Thus, a favorite remedy for early syphilis is the hydrargyrum oxidum nigrum Hahnemanni, in a state of trituration, in doses of $\frac{1}{8}$ to $\frac{1}{16}$ of a grain. The same authority highly recommends the administration of other remedies, such as corrosive sublimate, cyanide of mercury, arsenious acid, etc., in the form of triturations, as being more soluble.

In acute eczema, Dr. Piffard believes that rhus toxicodendron will cut short the attack if taken at the beginning; and he adds that $\frac{1}{100}$ of a drop of a good tincture is not too much to begin with.

# International Medical Congress.

*Held in London, England, August 3 to 9, 1881.*

(Special Report for THE MEDICAL RECORD.)

## GENERAL SESSION.

FIRST DAY—WEDNESDAY, AUGUST 3D.

THE seventh meeting of the International Medical Congress was formally inaugurated Wednesday, August 3d, at 11 A.M., in St. James's Hall, London, by His Royal Highness the Prince of Wales. When the doors of the hall were opened at ten o'clock, an hour before the time announced for proceedings to commence, there was already a large crowd of gentlemen, most of them foreigners, in waiting, and by half an hour later the greater portion of the large hall was filled. Many of the foreign delegates wore their decorations, the glittering array of stars and crosses of which formed a strange contrast to the undecorated coats of our equally distinguished American medical men. Nearly three thousand members of the Congress were present. No female physicians were allowed to attend as delegates.

### DISTINGUISHED MEN ON THE PLATFORM.

The advent upon the platform of some of the most distinguished visitors was the signal for great applause. Professor Virchow, of Berlin, coming in for an ovation at the hands of his many admirers. A similar tribute was also paid to Professor Charcot, of Paris, and many others. Amongst those present at the commencement of the proceedings, were Professor Acland (Oxford), Dr. M. Acosta (Spain), Professor Albernese (Palermo), Dr. C. Allbutt (Leeds), Professor M'Call Anderson (Glasgow), Dr. Fordyce Barker (New York), Dr. Bayer (Brussels), Dr. Lionel S. Beale, Dr. Benedikt (Vienna), Sir J. Risdin Bennett, Dr. Bouchert (Paris), Professor Cowen Bottini (Milan), Dr. Brandis (Auchen), Dr. Braem (Vienna), Dr. Brinelli (Rome), Professor Businelli (Rome), Dr. Byrd (Illinois), Dr. Cheavadia (Naples), Professor Azzio Casselli (Reggio Emilia), Dr. Lucas Championnière (Paris), Dr. Kraus (Vienna), Sir. W. Gull, Cardinal Manning, Sir R. Loyd-Lindsay, V.C., M.P., Dr. Chessnell, Canon Barry, the Bishop of London, Professor Tyndall, Sir Henry Thompson, Surgeon-Major de Chaumont (Netley), Professor Chauveau (Lyons), Mr. Andrew Clark, Dr. Cohen (Hamburg), Sir J. Rose, — Cormack (Paris), Professor Donders (Utrecht), Dr. Matthews Duncan, Professor Esmarch (Kiel), Dr. Austin Flint (New York), Professor Fonssagrives (Montpellier), Dr. Galezowski (Paris), Dr. W. A. Guy, Dr. Hans von Hebra (Vienna), Mr. Prescott Hewitt, Professor Kölliker (Würzburg), Professor Komad (Amsterdam), Dr. C. E. Lyster, Dr. Quain, Professor Pignocco (Palermo), Professor Reverdin (Geneva), Dr. Lydygier (Kulm), Dr. N. Sincinberghi (Rome), Professor Grainger Stewart (Edinburgh), Professor Trelat (Paris), Professor Trendelenburg (Rostock), Professor Erasmus Wilson, Dr. Wunderlich (Stettin), Dr. Wywodzoff (St. Petersburg), Professor Huxley, etc.

### ARRIVAL OF THE PRINCE OF WALES.

The Prince of Wales did not arrive at the hall until twenty-five minutes past eleven. His Royal Highness was received at the doors by Sir William Jenner, Sir William Gull, Sir James Paget, Mr. M'Cormac, the Secretary-General, and other members of the committee, and was conducted by them to the platform.

### ADDRESS OF SIR WILLIAM JENNER.

The chair was taken by Sir W. Jenner, K.C.B., who was *ex officio* Chairman of the General Committee, but who announced that it would be his duty to resign it to the President of the Congress as soon as the latter was elected. In a short but able address he acknowledged the royal support to the Congress, and referred to the beneficent objects it had in view, and was warmly cheered at the several points he made.

### REPORT OF THE SECRETARY-GENERAL.

MR. M'CORMAC, Honorary Secretary-General, then read the report of the executive committee, giving an account of the origin of the Congress, which was decided on at the International Medical Congress held in Amsterdam last year. In drawing attention to the fact that, with the exception of the honorary vice-presidents, all the gentlemen nominated for election as officers of the Congress belonged to England, the committee pointed out that the task of organizing the Congress had been considerable, and that it was desirable that those engaged in the work should be readily and constantly accessible. He then proceeded to present some details of the work that had been done to insure the success of the present Congress. An explanatory letter, giving a short account of the nature of the undertaking, had been sent to every practitioner in the United Kingdom and the colonies; notice of the intention to hold a congress was given to all the universities and schools in North America, and to 3,305 medical men in the various States; and similar circulars, either in French, German, Italian, or Spanish, were forwarded to the universities, medical societies, and a large proportion of the medical men of France, Germany, Austria, Hungary, Italy, Spain, Portugal, Scandinavia, Russia, Turkey, South America, India, China, and Japan. Copies of the programme had been sent to two hundred and eight medical journals, and altogether more than 120,000 circular notices had been sent out. Letters to reigning sovereigns, explaining the objects of the Congress, had been graciously acknowledged.

The report gave the names of the following gentlemen who had been commissioned by their several Governments to attend the Congress and report its proceedings:—For the Argentine Government, Professor William Rawson, of Buenos Ayres; for the Austrian Government, Professor Schnitzler, and for the Minister of Public Instruction, Dr. Hans Ritter von Hebra; for the Hungarian Government, Dr. L. Grosz de Csatar, and for the Minister of Public Instruction, Dr. A. Rozsahegyi; for the Belgian Government, Dr. Warlomont, Dr. Gille, Dr. Spaack, and for the Minister of Public Works, Dr. Libbrécht, of Ghent; for the Brazilian Government, the Baron de Theresopolis; for Egypt, Dr. Osman Bey; for the French Government, Professor Pasteur; for the Minister of War, Professor Gaujot and Dr. Poncet, of Paris, and for the Minister of Public Instruction, Dr. Worms; for Her Imperial Majesty the German Empress, Professor Küster, Berlin; for the Bavarian Government, Professor Ranke and Oberstabsarzt Dr. Port, of Munich; for the Prussian Minister of War, Generalarzt Dr. Coler, of Berlin; for the Saxon War Department, Generalarzt Dr. W. Roth, of Dresden, and Oberstabsarzt Dr. Starke, of Colberg; for the Saxon Minister of Internal Affairs, Geheimrath Dr.

Günther; for Italy, Professor Commendatore Semmola, of Naples, Professor Chevaliere Murri, of Bologna, and Professor Mazzoni; for His Majesty the King of the Netherlands, Professor H. Snellen, of Utrecht, and Dr. Guye, of Amsterdam; for the Grand Duchy of Luxemburg, Dr. Paul Koch; for Roumania, Dr. Marcovitch; for the Russian Ministry of the Imperial Household, Dr. Higginbotham, of St. Petersburg; for the Imperial University of Kazan, Professor Dr. Leon Levschin; for His Majesty the King of Spain, Inspector-General Don Nicasio di Landay Alvares and Inspector-General Dr. Ferradas y Rodriguez; for the Spanish Minister of Marine, Dr. Juan Acosta, Inspector of Medicine in the Navy; for the Swedish Government, Professor Carl J. Rossander, of Stockholm; for the Norwegian Army Medical Department, Dr. Charles Smith, of Bergen, and Dr. L. Dahl; for the Swiss Confederation, Dr. Joel, of Lausanne; for the United States of America, Surgeon J. S. Billings, Washington, D. C., for the War Department, and Surgeon Brown for the Navy Department.

The report further stated that full information on the business of the Congress had been forwarded to all foreign countries, and the result had been the delegation of gentlemen from all the civilized countries of the world to the number of 2,450.

FOREIGN VICE-PRESIDENTS.

Among those who had accepted the invitation to be nominated Foreign Vice-Presidents were: Professor Baccelli, Rome (who was prevented by business of state from attending); Dr. Fordyce Barker, New York; Dr. Billings, Washington; Dr. Bigelow, Boston; Professor Brown-Séquard, Paris; Professor Busch, Bonn; Professor Charcot, Paris; Professor Chauveau, Lyons; Professor Cornil, Paris; Professor Donders, Utrecht; Professor Esmarch, Kiel; Dr. Austin Flint, New York; Professor Foville, Paris; Professor Frerichs, Berlin; Professor Goltz, Strasburg; Professor Gerhardt, Wurzburg; Professor Jules Guérin, Paris; Professor Holmgren, Upsala; Professor Hannover, Copenhagen; Professor His, Leipsic; Professor Hardy, Paris; Professor Horner, Zürich; Professor Kölliker, Wurzburg; Professor Klebs, Prague; Professor von Langenbeck, Berlin; Professor Le Fort, Paris; Professor Loven, Stockholm; Professor Oscar Liebreich, Berlin; Dr. Henri Guéneau de Mussy, Paris; Professor van Overbeek de Meijer, Utrecht; Professor Ollier, Lyons; Professor Panum, Copenhagen; Professor Pasteur, Paris; Professor Pflüger, Bonn; Professor Pantaleoni, Rome; Professor Santesson, Stockholm; Professor von Slawjansky, St. Petersburg; Professor Stokvis, Amsterdam; Professor Tarnier, Paris; Professor Trélat, Paris; Professor Tilanus, Amsterdam; Professor Varentrapp, Frankfort; Professor Verneuil, Paris; Professor Virchow, Berlin; Professor Volkmann, Halle; Professor Warlomont, Brussels; and Professor von Zehender, Rostock. In addition to those legally qualified to practise medicine in their respective countries, a certain number of home and foreign pharmacists of distinction had been invited as extraordinary members, and also some eminent dentists and physiologists who were not medical men. A museum had been formed, and in addition to a collection of objects of great professional interest, there would, in connection with it, be a daily demonstration of patients affected by different forms of disease. In commemoration of this great medical meeting, a medal has been struck. Her Majesty the Queen had expressed her approval of this memorial, to the preparation of which some of our first artists had given their assistance.

OFFICERS ELECT.

Sir J. Risdon Bennett moved a resolution appointing Sir James Paget, President, and Mr. William M'Cormac, General Secretary, and the several gentlemen whose names were mentioned in the report as Vice-Presidents of the Congress and Vice-Presidents of the various sections, and all the other officers. He referred to the very complete literature of the Congress which had been prepared. While he was welcoming, in French, the delegates, the Crown Prince of Prussia arrived and was greeted with great heartiness and cordiality by the immense assembly.

Professor Donders, of Utrecht, who was President of the Congress of 1879, congratulated those who had undertaken the organization of this meeting upon the success which had attended their efforts. He looked for valuable additions to medical science from their deliberations.

The resolution being carried, Sir W. Jenner presented to the Prince of Wales one of the commemorative medals, and Sir James Paget, amid loud cheering, took his seat as President of the Congress.

THE OPENING OF THE CONGRESS BY THE PRINCE OF WALES.

The Prince of Wales, who warmly shook hands with the newly elected President, then rose and said:

Your Imperial Highness and Gentlemen: I gladly complied with the request that I should be patron of the International Medical Congress of 1881, and among many reasons for so doing was my conviction that few things can tend more to the welfare of mankind than that educated men of all nations should from time to time meet together for the promotion of the branches of knowledge to which they devote themselves. The intercourse and the mutual esteem of nations have often been advanced by great international exhibitions, and I look back with pleasure to those with which I have been connected; but when conferences are held among those who in all parts of the world apply themselves to the study of science, even greater international benefits may, I think, be confidently anticipated, more especially in the study of medicine and surgery, for in these the effects of climate and of national habits must give to the practitioners of each nation opportunities, not only of acquiring knowledge, but of imparting knowledge to those of their *confrères* whom they meet in congress. I venture to think, gentlemen, that the Executive Committee have acted wisely in instituting sections for the discussion of a very wide range of subjects, including not only the sciences on which medical knowledge is founded, but many of its most practical applications, and I am very happy to see that so great scope will be granted for the discussion of important questions relating to the public health, to the cure of the sick in hospitals and in the houses of the poor, and to the welfare of the army and navy. The devotion with which many members of the medical profession readily share the dangers of climate and the fatigues and dangers of war, and the many risks which must be encountered in the study of means, not only for the remedy, but for the prevention of disease, deserves the warmest acknowledgment from the public. I have great satisfaction in believing, in seeing this crowded hall, that I may already regard the Congress as successful in having

attracted a number never hitherto equalled of medical men from all parts of this kingdom, as well as from every country in Europe, from the United States, and from other parts of the world. The list of officers of the Congress, including, as it does, the names of those distinguished in every branch of medical science, shows how heartily the proposal to hold the meeting in London has been received. I think it speaks well for the good feeling of the profession that there should have been so warm a response to the invitations. How cordially the proposal has been received may be seen not only in the large number of visitors, but in the fact that they include a large proportion of those who enjoy a high reputation not only in their own countries, but throughout the world. I sincerely congratulate the Reception Committee on this good promise of complete success, and I trust that at the close of the Congress they will feel rewarded for the labor they have bestowed upon it. The report, which the Secretary-General, Mr. M'Cormac, has read, will have explained how great have been his labors. He will hereafter be well repaid, and I am sure Mr. M'Cormac is sensible that he will be recompensed even for his great exertions by the assurance that the progress of the important science of medicine has been materially promoted, for any addition to the knowledge of medicine must always be followed by an increase in the happiness of mankind.

THE OPENING ADDRESS

was then delivered by the President, SIR JAMES PAGET, BART. After referring to the composition of the Congress, the diverse characters of its members, and the various methods of study which had gained eminence for each, he dwelt upon the necessity of utilizing the apparent diversity of thought into a concentrated and harmonious whole. In works done by dissimilar and independent minds, dispersed in different fields of study, or only gathered into self-assorted groups, there was apt to be discord and great waste of power. There was, therefore, need that the workers should from time to time be brought to some consent and unity of purpose; that they should have opportunity for conference and mutual criticism, for mutual help and the tests of free discussion. This it was which, on the largest scale and most effectually, the Congress might achieve; not, indeed, by striving after a useless and happily impossible uniformity of mind or method, but by diminishing the lesser evil of waste and discord which was attached to the far greater good of diversity and independence. Now, as in numbers and variety the Congress might represent the whole multitude of workers everywhere dispersed, so in its gathering and concord it might represent a common consent that, though apart and different, yet the work was and should be essentially one; in all its parts mutually dependent, mutually helpful—in no part complete or self-sufficient. It might seem to be a denial of the declaration of unity that, after this general meeting the Congress should separate into sections more numerous than on any former occasion. He would speak of these sections to defend them; for some had maintained that, in such a division of studies, there was a mischievous dispersion of forces. He observed that the sections which we have instituted are only some of those which are already recognized, in many countries, in separate societies, each of which has its own place and rules of self-government, and its own literature. And the division had taken place naturally, in the course of events which could not be hindered. For the partial separation of medicine, first from the other natural sciences, and now into sections of its own, had been due to the increase of knowledge being far greater than the increase of individual mental power. He did not doubt that the average mental power constantly increased in the successive generations of all well-trained peoples; but it did not increase so fast as knowledge does, and thus, in every science, a small portion of the whole sum of knowledge had become as much as even a large mind can hold and duly cultivate. Many of us might, for practical life, have a fair acquaintance with many parts of our science, but none can hold it all; and for complete knowledge, or for research, or for safely thinking out beyond what was known, no one could hope for success unless by limiting himself within the few divisions of the science for which, by nature or by education, he was best fitted. Thus, the division into sections was only an instance of that division of labor which, in every prosperous nation, we see in every field of active life, and which was always justified by more work better done. Moreover, it could not be said that in any of our sections there was not enough for a full strong mind to do. If any one doubted this, he might try his own strength in the discussions of several of them. In truth, the fault of specialism was not in narrowness, but in the shallowness and the belief in self-sufficiency with which it was apt to be associated. If the field of any specialty in science was narrow, it could be dug deeply. In science, as in mining, a very narrow shaft, if only it be carried deep enough, might reach the richest stores of wealth and find use for all the appliances of scientific art. Not in medicine alone, but in every department of knowledge, some of the grandest results of research and of learning, broad and deep, were to be found in monographs on subjects that, to the common mind, seemed small and trivial.

Study in such a Congress might be a useful remedy for self-sufficiency. Here every group might find a rare occasion, not only for an opportune assertion of the supreme excellence of its own range and mode of study, but for the observation of the work of every other. Each section might show that its own facts must be deemed sure, and that by them every suggestion from without must be tested; but each might learn to doubt every inference of its own which was not consistent with the facts or reasonable beliefs of others; each might observe how much there was in the knowledge of others which should be mingled with its own; and the sum of all might be the wholesome conviction of all, that we cannot justly estimate the value of a doctrine in one part of our science till it has been tried in many or in all. The test of truth in every part should be in the patient and impartial trial of its adjustment with what was true in every other. For every fact in science, wherever gathered, had not only a present value, which we might be able to estimate, but a living and germinal power of which none could guess the issue. It would be difficult to think of anything that seemed less likely to acquire practical utility than those researches of the few naturalists who, from Leeuwenhoeck to Ehrenberg, had studied the most minute of living things, the Vibrionidæ. Men boasting themselves as practical might ask, "What good can can come of it?" Time and scientific industry had answered, "This good: those researches had given a truer form to one of the most important practical doctrines of organic chemistry; they had introduced a great beneficial change in the most practical

part of surgery; they were leading to one as great in the practice of medicine; they concerned the highest interests of agriculture, and their power is not yet exhausted." And as practical men were, in this instance, incompetent judges of the value of scientific facts, so were men of science at fault when they missed the discovery of anæsthetics. Year after year the influences of laughing-gas and of ether were shown: the one fell to the level of the wonders displayed by itinerant lecturers, students made fun with the other; they were the merest practical men, men looking for nothing but what might be straightway useful, who made the great discovery which had borne fruit not only in the mitigation of suffering, but in a wide range of physiological science.

The history of science had many similar facts, and they might teach that any man would be both wise and dutiful if he would patiently and thoughtfully do the best he could in the field of work in which, whether by choice or chance, his lot had been cast.

The best work of the International Congress was in the clearing and strengthening of the knowledge of realities; in bringing, year after year, all its force of numbers and varieties of minds to press forward the demonstration and diffusion of truth as nearly to completion as might from year to year be possible. Thus, chiefly, the Congress might maintain and invigorate the life of our science. And the progress of science must be as that of life. It sounded well to speak of the temple of science and of building and crowning the edifice. But the body of science was not as any dead thing of human work, however beautiful; it was as something living, capable of development and a better growth in every part. For as in all life the attainment of the highest condition was only possible through the timely passing-by of the less good, that it might be replaced by the better, so was it in science. As time passed, that which seemed true and was very good became relatively imperfect truth, and the truth more nearly perfect took its place. In the certainty of this progress, the great question was, What should we contribute to it? It would not be easy to match the recent past. The advance of medical knowledge within one's memory was amazing, whether reckoned in the wonders of the science not yet applied, or in practical results in the general lengthening of life, or, which was still better, in the prevention and decrease of pain and misery, and in the increase of working power. He could not count or recount all that in this time had been done; and he supposed there were very few, if any, who could justly tell whether the progress of medicine had been equal to that of any other great branch of knowledge during the same time. He believed it had been; he knew that the same rate of progress could not be maintained without the constant and wise work of thousands of good intellects; and the mere maintenance of the same rate was not enough, for the rate of the progress of science should constantly increase. That in the last fifty years was at least twice as great as that in the previous fifty. What would it be in the next, or, for a more useful question, What should we contribute to it?

"In the number and intensity of the questions brought before us,'" said he, "we may see something of our responsibility. If we could gather into thought the amounts of misery or happiness, of helplessness or of power for work, which may depend on the answers to all the questions that will come before us, this might be a measure of our responsibility. But we cannot count it; let us imagine it; we cannot even in imagination exaggerate it. Let us bear it always in our mind, and remind ourselves that our responsibility will constantly increase. For, as men become in the best sense better educated, and the influence of scientific knowledge on their moral and social state increases, so, among all sciences there is none of which the influence and, therefore, the responsibility will increase more than ours; because none more intimately concerns man's happiness and working power.

"But, more clearly in the recollection of the Congress, we may be reminded that in our science there may be, or, rather, there really is, a complete community of interest among men of all nations. On all the questions before us we can differ, discuss, dispute, and stand in earnest rivalry; but all consistently with friendship, all with readiness to wait patiently till more knowledge shall decide which is in the right. Let us resolutely hold to this when we are apart: let our internationality be a clear, abiding sentiment, to be, as now, declared and celebrated at appointed times, but never to be forgotten; we may, perhaps, help to gain a new honor for science. if we thus suggest that in many more things, if they were as deeply and dispassionately studied, there might be found the same complete identity of international interests as in ours.

"And then, let us always remind ourselves of the nobility of our calling. I dare to claim for it, that among all the sciences, ours, in the pursuit and use of truth, offers the most complete and constant union of those three qualities which have the greatest charm for pure and active minds—novelty, utility, and charity. These three, which are sometimes in so lamentable disunion, as in the attractions of novelty without either utility or charity, are in our researches so combined that, unless by force or wilful wrong, they can hardly be put asunder. And each of them is admirable in its kind. For in every search for truth we can not only exercise curiosity, and have the delight—the really elemental happiness—of watching the unveiling of a mystery, but, on the way to truth, if we look well round us, we shall see that we are passing among wonders more than the eye or mind can fully apprehend. And as one of the perfections of nature is that, in all her works, wonder is harmonized with utility, so is it with our science. In every truth attained there is utility either at hand or among the certainties of the future. And this utility is not selfish: it is not in any degree correlative with money-making; it may generally be estimated in the welfare of others better than in our own. Some of us may, indeed, make money and grow rich; but many of those that minister even to the follies and vices of mankind can make much more money than we. In all things costly and vainglorious they would far surpass us if we would compete with them. We had better not compete where wealth is the highest evidence of success; we can compete with the world in the nobler ambition of being counted among the learned and the good who strive to make the future better and happier than the past. And to this we shall attain if we will remind ourselves that, as in every pursuit of knowledge there is the charm of novelty, and in every attainment of truth utility, so in every use of it there may be charity. I do not mean only the charity which is in hospitals or in the service of the poor, great as is the privilege of our calling in that we may be its chief ministers; but that wider charity which is practised in a constant sympathy and gentleness, in patience and self-devotion. And it is surely fair to hold that, as in every search for knowl-

edge we may strengthen our intellectual power, so in every practical employment of it we may, if we will, improve our moral nature; we may obey the whole law of Christian love, we may illustrate the highest induction of scientific philanthropy.

"Let us, then, resolve to devote ourselves to the promotion of the whole science, art, and charity of medicine. Let this resolve be to us as a vow of brotherhood; and may God help us in our work."

---

### Afternoon Session.

Sir James Paget, President, in the Chair.

#### ADDRESS BY PROFESSOR VIRCHOW: THE VALUE OF EXPERIMENTAL PATHOLOGY.

The Congress was called to order by the President, Sir James Paget.

Professor Virchow, of Berlin, delivered an address, in German, on the value of experimental pathology. He commenced by referring to the great activity of the anti-vivisectionists, and the harm they had done to experimental physiology and pathology. The latter, as well as the former, had its claims for defence from all scientific men. In connection with the general subject, he proceeded to examine the decline of the science of symptoms, and of the falling off of an interest in the study of their relations to pathology. Were symptoms no longer to possess any significance for the medical man? He would say, certainly not. At the same time, for the scientific medical man, symptoms were only the expression of a hidden force; it was his business to follow up this hidden force to its seat in the human system, and there learn its nature and causes. The first question of the pathologist, as of the biologist, was, Where? Consequently, whether they probed the seat of disease with the anatomical knife, or whether they merely confined themselves to observation, the mode of proceeding was essentially anatomical. It was the recognition of this principle which, in a few decades, had changed the whole face of science. Especially was this change observable in the treatment of ophthalmic diseases. Every practitioner now studied the seat of the evil itself, and not merely its symptoms. Even the anti-vivisectionists recognized the value of this method, forgetting, however, that every organ of the body was not so favorably situated for observation as the eye. The principle of modern medicine, in a word, was that of localization. Vivisection dated really from the time of Harvey. Now, Harvey's services the strongest opponents of vivisection themselves recognized; but, said they, since Harvey's time vivisection has revealed nothing important. They were not aware that that very element in the phenomena of Harvey's circulation of the blood, which most affected the vital attributes of the organs of circulation, remained untouched. Whence was derived the activity of the heart? What part in the motion and the distribution of the blood did the organs of the body play? What share devolved upon the arteries, the veins, and the capillary vessels? All those questions were of the highest practical importance, and none of them could be solved otherwise than by experiments upon living animals. Those questions Harvey could not settle, because, in his time, higher anatomy had not been developed. Who then knew anything of the heart or of the nerve? Not till these latter days did men understand the peculiarities of the circulation of the blood. The pulse, that highly-prized object of the old symptomatology, was now intelligible. It was no longer regarded as presenting the symptom of this or that disease, but as the sign of the existence or non-existence of certain principles of activity, of the strength or the weakness, the irritation or the relaxation of certain tissues. The development of physiology and pathology paved the way for the later experimenters, and accounted for the long interval which had elapsed since Harvey's time. Our modern science, indeed, had been but of slow growth, but as it grew, one thing became clearer and clearer—namely, the principle of inherent vitality—the *vita propria* of each section of the body (*das Eigenleben der Theile*). Every step showed more conclusively that the supposed existence of life, as a large and separate entity, was a fiction. Life existed everywhere in the body; and disease and life—or, to speak more properly, diseased and healthy life—existed perfectly well side by side, in the sense that disease indicated so much abstracted from the healthy life. Disease, in fact, was no longer spiritualized: it was a material entity, a real living thing, a cellular change (*die veränderte Zelle*). Had all these discoveries resulted in tangible advantage to us? Was it worth while for such results that so many animals should suffer pain and death? These questions he could confidently answer in the affirmative. How, he asked, could further important results in the science of healing be looked for if experiments with animals were prohibited? How else, for instance, could the operation of chloral have been discovered? It could not seriously be expected that medical men should make their own bodies the subject of experiments with very various and perhaps poisonous substances. They were already more exposed to danger in their contact with disease than any other class of the population. If no suffering whatever was to be inflicted upon animals, our social habits in relation to horses, dogs, etc., would be very much altered. It was absurd to contend, as the vivisectionists did, in effect, that suffering was worse than death. There was no greater hardship involved in putting animals to death, in order to promote the public welfare by means of scientific experiment, than in killing them for food. Abuses, of course, he did not defend, but so long as every person who owned an animal had the right of killing it, necessarily it followed that scientific experiments involving the death of animals were justifiable. And of the necessity of these experiments, and the mode of carrying them out, the investigator alone could be the judge, though, as to the question of time and place, a judicial authority might fairly have something to say.

At the conclusion of his address, which lasted over an hour, and which, marked as it was by many gleams of humor and passages of eloquence, evoked much applause, the learned Professor pleaded that vivisectionists should not be regarded as heartless barbarians, but as men who were working to promote the welfare of humanity. Of science it might be said, as Bacon said of the sun—"Palatia et cloacas ingreditur, neque tamen polluitur."

---

After the transaction of business of a miscellaneous character, the Congress adjourned until the regular session of Thursday.

#### SOCIAL ENTERTAINMENTS.

At noon the Prince of Wales honored Sir James Paget with his company to lunch, and a select party was invited to meet His Royal Highness. In the evening

the Prince of Wales, the Crown Prince of Prussia, and Prince Henry of Germany, dined at Willis's Rooms with Sir William Gull and a party of over 100 members of the Congress. In returning thanks for the toast of his own health, the Prince of Wales spoke of the unique character of the present gathering, and expressed his conviction that the Congress could not fail to be of the utmost service to the whole world, and wound up his speech by the words, "*L'union fait la force.*" H.I. and R.H. the Crown Prince of Germany replied to the toast of the distinguished foreign guests. The Prince of Wales, in proposing Sir W. Gull's health, expressed in the warmest terms his personal gratitute for his attention during his long illness; and Sir W. Gull, in reply, disclaimed the sole credit of the attendance on the Prince, and spoke in high terms of the cordial and brotherly assistance he had received from Sir W. Jenner.

The conversazione at South Kensington, given in the evening by the English members to the Congress, was attended by over five thousand persons, but there was abundant accommodation for even this large number in the spacious courts, picture galleries, and garden. The arrangements were excellent. There was no overcrowding, even in the refreshment-rooms, and its perfect success was the result, not of chance, but of skilful arrangements. The Prince of Wales and his illustrious brother-in-law also honored the Congress by attending this soirée and by staying a considerable time. And thus ended a day marked by gatherings unique in character and interest, and it is no exaggeration to say that the most captious critic would fail to detect a single failure of the arrangements at any point.

A considerable number of the Executive Committee were present at the reception on Tuesday afternoon, which was largely attended by visitors to the metropolis. On Tuesday evening, various private entertainments were given, among them being a reception by the Hon. Secretary-General at his private house, which was attended by several hundred members, including some of the most distinguished of the foreigners. Mr. Rogers on the same evening received the members of the Odontological Section and some others at the Marlborough Rooms.

---

The various sections met and organized at 3 P.M., when most of the addresses by the respective presidents were delivered, after which the subjects set down for the day were presented. In the section on Anatomy, John Struthers, M.D., of Aberdeen, gave a paper on "The Processus Supracondyloideus Humeri of Man;" while Dr. Facsebeck, of Brunswick, devoted himself to the motor portion of the trigeminus nerve.

In the section on Pathology and Morbid Anatomy, Professor Klebs, of Prague, discussed the relations of minute organisms to certain specific diseases, Dr. H. Vandyke Carter taking up a special branch of the same subject in the aspects of the blood spirillum in relapsing fever.

In the section on Medicine, C. E. Brown-Séquard dealt with localization of diseases in the brain and spinal cord so far as pathognomonic and diagnostic, and Dr. J. Hughlings Jackson, F.R.S., discussed epileptic convulsions from cerebral disease.

In the Surgical Section, a commencement was made by Mr. Spencer Wells, who described recent advances in the surgical treatment of intraperitoneal tumors. Mr. Lawson Tait went into the question of recent advances in abdominal surgery.

## MEETINGS OF THE SECTIONS.

### SECTION ON SURGERY.

FIRST DAY—WEDNESDAY, AUGUST 3D.

JOHN ERIC ERICHSEN, F.R.S., PRESIDENT, IN THE CHAIR.

SUBJECTS FOR DISCUSSION.

After a few preliminary statements, the President of the Section remarked as follows: The executive of this section has proposed eight subjects for the consideration of its members. It is hoped that these will be found to include the more important surgical questions that are at present most prominently before the profession. The short time at our disposal, which will scarcely enable us to do full justice even to these subjects, has prevented the possibility of our bringing forward other and perhaps equally interesting questions; but some of these will be found to have received consideration in the papers which will be read, either *in extenso* or in abstract, as time may allow.

I will now briefly refer to the more important subjects that have been set down for our consideration.

*First.*—In no department of surgery has a more marked or a more brilliant advance been made of late years than in that which concerns the operative treatment of intra-peritoneal tumors.

The establishment of ovariotomy as a recognized surgical operation has now long been matter of history; but the perfection of safety to which it has of late years been carried, by the improvement of its details, has led the way to a vast and rapid extension of operative surgery for the cure or relief of various diseased abdominal organs. The uterus and the spleen, the stomach, the pylorus and the colon, have each and all been subjected to the scalpel of the surgeon, with what success has yet to be determined; and it is for you to decide whether some, at least, of these operations constitute real and solid advances in our art, or whether they are rather to be regarded as bold and skilful experiments on the endurance and reparative power of the human frame—whether in fact they are surgical triumphs or operative audacities. There must, indeed, be a limit to the progress of operative surgery in this direction. Are we at present in a position to define it? There cannot always be new fields for conquest by the knife; there must be portions of the human frame that will ever remain sacred from its intrusion, at least in the hands of the surgeon. May there not be some reason to fear lest the very perfection to which ovariotomy has been carried may lead to an over-sanguine expectation of the value and the safety of the abdominal section and exploration when applied to the diagnosis or cure of diseases of other and very dissimilar organs, in which but little of ultimate advantage, and certainly much of immediate peril, may be expected from operative interference?

*Second.*—In the discussion of the next great question, I would submit that we may, with advantage, direct our attention less to the mere mechanical—the simple operative part of the business—the details of which are now well understood, than to the consideration of those higher questions as to the diagnosis and nature of the various forms of renal disease, in which nephrotomy and nephrectomy may be respectively used, with a reasonable hope of relief or cure. And in considering the prospects afforded by these operations in the improvement of

the health and the mitigation of the sufferings of the patient, it is surely not the least interesting point for us to study the after-physiological effects produced on the system by the extirpation of so important and eliminatory organ as the kidney.

*Third.*—We naturally pass from the consideration of operations on the kidney to that of those which implicate the bladder; and in doing so we have specially to direct our attention to the question as to what advances have of late been made in lithotomy and lithotrity.

In lithotomy we see much of change, possibly something of novelty, but not so certainly anything of real progress. Have we indeed advanced one single step either in the perfection or in the results of that operation since the days of Cheselden, of Martineau, or of Crosse, not to mention the names of more recent, but equally illustrious surgeons and successful operators? The revived median operation, the combination of it with lithotrity, the suprapubic, whether done antiseptically or not, have certainly not been very encouraging in their results, and can scarcely claim to be considered in the light of an advance on the old lateral operation in skilful hands. But yet we must admit that these methods of lithotomy may deserve this consideration—that possibly in some forms of calculus, and in certain conditions of the urinary organs, a wise eclecticism may be exercised in the choice of one or other of them.

In lithotrity, however, it is probable that a great and real advance has been made, and certainly it is undoubted that a complete revolution has been effected by the enterprise and skill of one of our American brethren, for it cannot be questioned that "Bigelow's operation" has completely changed the aspect of lithotrity, and there is every reason to believe that it constitutes one of those real advances in a method which marks an epoch not only in the history of the operation itself, but in the treatment of the disease to which it is applicable.

But here a fertile field opens up for our deliberation. We have to consider not only in what cases, as regards the mere size of calculus, "Bigelow's operation" may safely be used; but also, and far more important than this, the ultimate result both upon the bladder and the kidney of prolonged intravesical instrumentation. The mere question as to the comparative advantages of removal of stone, by one or by several sittings, is dwarfed by the more important one of determining the state of the bladder that results—not perhaps so much as concerns the life as the future comfort of the patient. It is here that information is much needed, and it is here that unfortunately, but for very obvious reasons, the lithotritist himself may in many cases be unable to furnish it.

*Fourth.*—Prehistoric man was doubtless a victim of injury before he became a sufferer from disease, and the treatment of wounds constituted probably the first effort of the healing art. From the earliest dawn of human intelligence the attempt to cure a wound must have suggested itself to man, and yet at the close of the nineteenth century we are still discussing the best methods of doing this, and the causes of their failure. There is still difference of opinion and of practice among surgeons, not only as to the comparative advantages of the "open air" method, and that in which all atmospheric contact is carefully guarded against; of the "dry" and of the "moist" system of dressing; as to whether the "antiseptic method" in a modified form suffices, or whether the more elaborate system of local treatment before, during, and after an operation, which has been devised by the skill and worked out by the unwearied labor of Lister, be essential in all cases of operation wound. Not, of course, for its primary union—for this may be obtained by any and every of the methods mentioned. If it be contended that this system is necessary for the safety of the patient, and the due healing of the wound in some cases, has it been proven to be equally essential in traumatic lesions of all tissues, of all organs, and of all regions? These are questions that may well deserve the consideration of this section. But there are others of a yet wider character that must also engage our attention in any discussion on the best methods of securing primary union in wounds, for it is impossible to fail to recognize in the general constitutional state of the patient a most important factor in this direction; and we should be taking a narrow view of this many-sided question if we did not give due weight to the influence of those hygienic conditions which, if faulty, are inimical or even destructive to the due performance of those actions which are necessary for the maintenance of the organism in a healthy state, and for the proper nutrition and consequent repair of the tissues of the body. Is there no fear that in some of the modern systems of treating wounds we are in danger of expending all our precautions in the prevention of the local, and of ignoring the risk of a constitutional infection?

*Fifth.*—The treatment of aneurism is one of those great questions which from an early period in the history of modern surgery has occupied the attention of practitioners, and has undergone no little fluctuation. A few years ago the battle between the ligature and compression appeared to have been decided in favor of the latter; but the invention of improved ligatures, made of various kinds of animal tissue, and applied with antiseptic precautions, has once more inclined the balance of professional opinion toward the Hunterian operation. But now again the practice of compression has received renewed strength from the employment of Esmarch's elastic bandage in the cure of certain forms of external aneurism, and it is for you to determine in what cases it can be used with advantage, and in what way a cure is effected by its means. For in the treatment of aneurisms, as in that of so many other surgical diseases, the wiser and more scientific course is to follow a judicious system of selection in the method to be employed in each particular case, rather than to subject all to one unbending line of practice.

*Sixth.*—The treatment by resection of some forms of chronic and otherwise incurable joint diseases, has, in certain articulations and at suitable ages, met with universal approbation of surgeons, and the wide extension of the principles of "conservative surgery" is one of the most striking evidences of advance in our art in modern times. Resection has, however, of late years come to be extensively applied to the treatment of cases of articular disease which formerly were subjected to procedures of a less heroic character; and it will be for the members of this section to weigh carefully the wisdom of such a measure, and to contrast its results, both as regards the life of the patient and the after-utility of the limb, with those which may be obtained from the employment of milder means, such as absolute immobility with extension, and possibly, in some cases, simple incision of the articulation.

*Seventh.*—In considering the relations between

adenoma, sarcoma, and carcinoma in the mammary gland of the female, I would venture to submit that this subject has to be discussed here from its clinical rather than from its pathological side. We have here less to do with the ultimate structure of the tumors, with their histological affinities, with the parts that are played by epiblasts and mesoblasts, with what epithelium or connective-tissue cells can or cannot do, than with their clinical history, their differential diagnosis in their earlier stages, the best time for their removal by operation, the liability to recurrence after operation, and the possibility in recurrence of the substitution of one form of disease for another. With these, and such questions as these, we, as clinical surgeons, may advantageously occupy ourselves.

*Eighth.*—The last subject set down for discussion is one that has practical bearings of an importance that cannot be overestimated. There are few questions of the present day of deeper surgical or social interest than the far-reaching, the apparently illimitable and most pernicious extension of a syphilitic contamination of organs and of tissues; of the modifications impressed by it on other diseases that are the local developments of diathesis, whether strumous, tubercular, rheumatic, or gouty. Does the diathesis exercise any influence upon the form assumed by the syphilitic disease, and to what extent does it modify the characters presented by it in its primary and its secondary affections, more especially when the latter manifest themselves upon the skin or in the bones; how far are gummata and caries, psoriasis, and rupia the consequences of a constitutional impress, influencing the direction of the syphilitic poison? To what extent may rickets and gray granulations be the ultimate products of the syphilitic taint? These and various other questions will probably occupy the attention of those who enter on the discussion of this wide-spreading subject.

## SECTION ON ANATOMY.

### First Day—Wednesday, August 3d.

### Prof. W. H. Flower, LL.D., F.R.S., F.R.C.S., President, in the Chair.

**THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,**

was the title of the inaugural address by the President of the Section.

Prof. Flower gave a general outline of the history and contents of the museum which, for eighty years, the College of Surgeons had maintained for the benefit not only of its own members, but for that of the profession at large, and, indeed, of all who take any interest in biological science, whether the young student preparing for his examination, or the advanced worker who had there found materials for many an important contribution by which the boundaries of knowledge have been materially enlarged. To all such it was freely opened, without any fee or charge. Even the written or personal introduction of members, still nominally required, was never asked for on the four open days, from any intelligent or interested visitor; and on the one day of the week in which it was closed for cleaning, facilities are always given to those who are desirous of making special studies, and to the increased number of lady students, whether artistic, scholastic, or medical. Artists continually resort to the Museum to find opportunities for studying the anatomy of man and animals, which no other place in London afforded; and of late years it had been the means of a still wider diffusion of knowledge, by the visits which had been organized on summer Saturday afternoons, by various associations of artisans, to whom a popular demonstration of some part of its contents was usually given on each occasion by the conservator.

If the knowledge of organic nature was of any value to man, as on such knowledge the whole superstructure of their profession is built, there could be no question but that such an institution as he had sketched out must be one of pure and simple benefit. Its maintenance had been a worthy object, upon which the college had spent its care and its money; and whatever might be the changes which impending legislation may effect in the organization of the profession, he hoped that the great work begun by John Hunter, and carried on by those who, under the guidance and support of the Council of the College, had followed him in the care of the collection, might not be impaired or destroyed. Whether the whole of the charges of maintaining such a museum in all its parts on a continually extending scale should be the duty of one institution, like the College of Surgeons, or even of one profession, might be a question for future consideration; but, in the meantime, how easily could its preservation and future extension be rendered entirely independent of all the chances and changes of medical education and legislation, or even of government assistance and interference.

## SECTION ON OBSTETRICS.

### First Day—Wednesday, August 3d.

### Alfred H. McClintock, M.D., LL.D., President, in the Chair.

The President of the Section made the opening address. After an appropriate introduction, he stated that, inasmuch as this was the first occasion of the International Medical Congress meeting in London, it might not be inappropriate if he passed in review some of the more prominent among the many eminent obstetricians who lived and practised in London, and who, by their writings, teaching, and discoveries, had contributed in no small measure to the development of midwifery and gynecology, as well as to the medico-chirurgical fame of London.

In this retrospective glance, he found only one name standing out in the sixteenth century—Thomas Raynald, the translator of Eucarius Rhodion's celebrated treatise, "De partu Hominis." The original English edition, by Raynald, appeared about 1540, and was the first distinct treatise on Midwifery in the English language, and for over one hundred years was the sole guide and text-book of obstetric practitioners, male and female.

In the early part of the seventeenth century, the immortal William Harvey (*tanto nomini nullum par eulogium*) stood forth conspicuous, the splendor of his fame increasing as years roll on. He spent most of his time in London, being physician to the King; and he delivered courses of lectures at the Royal College of Physicians on anatomy and surgery.

Before the publication of his celebrated exercitations on generation, parturition, conception, etc., there were, according to Dr. Aveling, "but three works on midwifery in our language: these were translations from Rhodion, Rueff, and Guillemeau. Harvey's was the first book on midwifery written by an Englishman, printed in our own language, and the influence which it had upon the practice of the time

could with difficulty now be estimated. His claim therefore to eminence in obstetric medicine was beyond question."

Contemporary with Harvey was another remarkable man—Peter Chamberlen, the inventor of the midwifery forceps, indisputably the most valuable instrument of the whole *armamentarium chirurgicum*. Unfortunately for him, however, the brilliancy of his reputation was obscured by the unworthy selfish conduct which caused him to keep the instrument a secret for the aggrandizement of himself and family. He was the father of Dr. Hugh Chamberlen, the translator into English of Mauriceau's works. No less than five generations of the Chamberlen family had been eminent in the medical profession in London, and Dr. Peter, who attained a great age, had been physician to five English sovereigns.

Toward the close of this (seventeenth) century, Richard Wiseman, "Serjeant-Chirurgeon" to Charles I., published his treatise on surgery, in which he gave an excellent description of pelvic abscesses, consequent on parturition. He thus anticipated Puzos' essay on the same disease, and put forward much more rational and correct views as to its pathology.

The eighteenth century was destined to see a marvellous development of midwifery, as well as of many other arts and sciences. As might therefore be expected, London could boast of several eminent obstetricians at this period.

In chronological order, the first to be mentioned was Dr. John Arbuthnot, F.R.S. and F.R.C.P., physician to Queen Anne. Although he had left no enduring evidence of obstetric superiority, yet he was an eminent accoucheur in his day, and reflected infinite credit on his calling by his rare literary talents, his deep scholarship, and his exalted social position. He was skilled in everything that related to science, and held a prominent place among the ablest writers and wits of that augustan age, one of whom (Swift or Pope) alludes in his poetry to

"Arbuthnot's soft obstetric hand."

A man who was considered a friend and an equal by Parnell, Gay, Bolingbroke, Swift, and Pope, could not fail to adorn any pursuit to which he devoted his vast intellectual powers. Speaking of him, Swift said, "He has more wit than we all, and his humanity is equal to his wit."

The next to be mentioned was Dr. John Maubray, not on account of any peculiar merit in either of his works, "The Female Physician," and "Midwifery Brought to Perfection," but because he was reputed to have been the first public teacher of midwifery in Great Britain. He lectured at his house in Bond street so far back as the year 1724. Nearly contemporary with Maubray was Dr. Edmund Chapman. He was the second public teacher of midwifery in this city, and was entitled to our lasting gratitude for having been the first to publish to the world a description of that "noble instrument" (to use his own phrase), the obstetric forceps, the secret of which the Chamberlens kept to themselves for over fifty years. This he did in the "Edinburgh Medical Essays," and subsequently in his treatise "On the Improvement of Midwifery, Chiefly with Regard to the Operation"—the operation meaning the application of the forceps. The first edition of this book came out in 1733. About this same period also lived Sir Richard Manningham, F.R.S., a man of considerable learning, and of great reputation as a successful midwifery practitioner. He was author of some obstetric works of temporary consequence, and his claim to remembrance arose from the circumstance that, in the year 1739, he opened a ward in the Parochial Infirmary of St. James', Westminster, exclusively for the reception of parturient women, which was the first thing of the kind in Great Britain. Shortly afterward the idea was taken up and enlarged upon elsewhere, and the great Lying-in Hospital in Dublin was founded by Dr. Bartholomew Mosse, being the first hospital of the kind in the British Dominions.

The very same year that Sir Richard Manningham opened his obstetric ward in St. James' Infirmary, a surgeon from a small country town in Scotland established himself in London as an accoucheur, who ultimately effected the greatest reformation that had yet taken place in the principles and practice of obstetrics. This man was William Smellie, a name always to be respected wherever midwifery is cultivated as a science. For twenty years Smellie practised and taught here; and published the first volume of his celebrated treatise in 1751, and his splendid anatomical plates in 1754. Amongst his pupils who later on became eminent in the same branch of medicine, were William Hunter, Denman, David McBride (of Dublin), John George Roederer (subsequently Professor of Midwifery at Göttingen), Dr. James Lloyd, of Boston, U. S., and Dr. William Shippen, afterward Professor of Midwifery in the Pennsylvania University; these last being, according to Professor Parvin, "the two first American obstetric practitioners." Smellie possessed a wonderful capacity for work, and a clear judgment; but beyond and above this, he was endowed with a singularly accurate perception of facts, which made him a correct as well as a close observer of nature. Herein laid the secret of his unrivalled success as a reformer and improver of midwifery. He himself felt this to be so, for in reviewing his practice, he says, "I diligently attended to the course and operations of nature which occurred in my practice, regulating and improving myself by that infallible standard." (Case 186: Sydenham Society Edition). Truly he was, in the words of Dr. Hugh Miller, a "noble character and an example of earnest living."

A couple of years after Smellie settled in London, there came to live with him a young man from the Scottish county (Lanarkshire) of which Smellie himself was a native. This young man was no less a person than William Hunter, whose plates and descriptions of the human gravid uterus have gained their author a foremost rank among obstetric writers. By his great reputation as a lecturer and as an anatomist, aided no doubt by his prepossessing appearance, polished manners, and cultivated mind, Hunter proved a successful competitor of Smellie's in practice. Like him, he also gave special courses of lectures on midwifery, MS. notes of which are to be found in many libraries. In 1748, Hunter was appointed surgeon and man-midwife to Middlesex Hospital, and soon afterward to the British Lying-in Hospital; for though the physicians claim him as belonging to themselves, yet it cannot be disputed that Hunter was a surgeon and a member of the Corporation of Surgeons of this city. Besides being a rival, he was in some respects a contrast to Smellie. The school of obstetrics founded by the latter was not inaptly described by the late Tyler Smith as the mechanical school, from the importance it attached to the resources of art in aiding parturition. Hunter, on the other hand, placed extraordinary reliance on the powers of nature, and

trusted too much to tincture of time. Hence, his followers have been designated the physiological school; and, through the influence of his commanding authority, they formed a large section of the profession, and could boast some great names.

Although we may regard Hunter as one of ourselves, and appropriate much of the glory with which his name was invested, "yet it is necessary (as Dr. Duncan observes), with a view to justice, to point out that his obstetrical fame is chiefly anatomical, and that his greatest claim on our admiration and gratitude arises from his anatomical work and influence." (Harveian address, 1876.)

One of the greatest ornaments of that physiological school of accoucheurs founded by William Hunter was Thomas Denman, a man of remarkably sound judgment, great prudence, and of the highest moral integrity. Throughout half a century he lectured and practised in London. His work, entitled "An Introduction to the Practice of Midwifery," is well known. It had many peculiar excellences: the chief was his classification of labor, which was at once comprehensive, pathological, and practical, and thereby serves the highest purposes of any system of classification.

Did time permit, he could multiply these brief sketches so as as to include many other London obstetricians who lived since the commencement of the present century, but he contented himself, however, with a mere recital of their honored names, viz.: John Clarke, Osborne, Leake, Bland, Merriman, Charles Clarke, Gooch, David Davis, Blundel, John Ramsbotham, Marshall Hall, Robert Lee, Robert Ferguson, Rigby, Jun., Francis Ramsbotham, Granville, Ashwell, Lever, Locock, Waller, Murphy, Tyler Smith, Oldham.

## SECTION ON MEDICINE.

First Day—Wednesday, August 3d.

Sir William Gull, M.D., D.C.L., LL.D., F.R.S., President, in the Chair.

### THE ADDRESS OF THE PRESIDENT.

The President called the section to order, and then proceeded to deliver his opening address. In his introductory remarks he took occasion to refer to the great strides that had been taken within the past few years in the rational study of medicine, in that method which tended so directly toward the accumulation of facts rather than the promulgation of theory. Hence it was that in contradistinction with the old-fashioned doctrine of fluids, that of solidism, properly so-called, is widely reasserting itself in the science of living things; not as an *à priori* system, but through the progress of knowledge. The proximate conditions of pyrexia were no longer vaguely referred to nerve, but to definite nerve-centres; hyperæmia and inflammatory changes to sympathetic lesions; abnormal chemistry to the great respiratory centres; the strange conditions of Addison's disease, with its characteristic pigment, to the suprarenal bodies, themselves probably but nerve-centres, and related, at least by structure, to the system of the pituitary gland; epilepsy, supposed in Hippocratic times to be due to extraneous maleficent spiritual influences, was traceable to apparently trifling changes in a few gray nerve-cells. The specific fever-processes notoriously owe much of their character and intensity to the nervous system. Their relation to time, their occurrence only in warm-blooded animals, the great mortality they cause through nerve-exhaustion, and the immunity they left behind them, indicated that, whatever might be the nature or mode of operation of their several poisons, it was by implication of nerve-elements that fever obtained its chief clinical characteristics. Further, in the advance of "solidism," what could interest us more than the recent investigations on contagia? Perhaps no more important step had been made in practical pathology than the proof that some at least of these contagia were organized solids. This discovery, which had tried the patience, experimental skill, and scientific criticism of the best observers to establish, had brought us at length within view of that which had hitherto been so mysterious. To have been able to separate, though imperfectly, the contagious particles; to have come to the conclusion that no fever-poisons were soluble, was a hopeful preliminary toward forcing them to yield up the secret of their nature. If "solidism," as a theory of organic processes, wanted confirmation, we could point to nothing more striking than the present established views on putrefactive changes; and to the amazing fact, that the normal textures and fluids of the body resisted decomposition, unless invaded by microscopic organisms. He believed that hereafter all organic chemistry would be found to be simply the resultant of mechanical changes in organic solids?

## SECTION ON PATHOLOGY.

First Day—Wednesday, August 3d.

Samuel Wilks, M.D., F.R.S., President, in the Chair.

### PRESIDENT'S ADDRESS.

The President of the Section extended to the members present a few appropriate words of welcome, and then proceeded, without further introduction, to take a somewhat practical view of the general subject of pathology by considering it in its more direct relations with disease, decay, and death. Gradual and progressive decay was natural in every organic structure, as was also the process of repair. These processes were not, however pathological, and were not of themselves indicative of a diseased condition.

If, however, these occurred prematurely, they became abnormal, and might be strictly regarded as morbid. Therein there was one form of a pathological condition—a premature decay arising from the various causes which brought the organism to an end, either from their operating with unusual force, or from some inherent weakness in the body, which was unable to moderate their action. If all such potent influences, instead of driving the mechanism too quickly, and so bring it prematurely to an end, concentrated their forces upon one organ only, that organ would become, in ordinary parlance, diseased; but the process there set up might be of exactly the same nature as time would otherwise have produced. In comparatively young persons, for instance, we meet with fibroid and fatty changes in the heart and vessels, distention of the air-cells, alterations in the structure of bones and joints, which resembled in every respect those which age would have ordinarily induced. Therefore, many of the conditions which were called disease seemed nothing more than the result of the concentration on a particular organ of all such agencies as, under ordinary circumstances, brought about senile changes.

The pathologist, therefore, could not but regard the body, in the first place, in its physiological relations with its surroundings, and mark the alterations

which time produced. The physiologist was aware that the production of force must be accompanied by loss elsewhere, seeing that gain and loss were equal; and therefore, in observing organic life, he should regard the destructive processes as well as the formative. Life seemed to depend upon changes continually going on in relation with the atmosphere in which all living bodies were steeped. The burning of the fuel in oxygen supplied the forces necessary for living processes; we, therefore, although alive, were constantly being consumed. During so many years the body was undergoing slow destruction, and this process occurred much more rapidly in some persons and in some animals than in others. Why one creature should live longer or burn out sooner than another was not clear: why, for example, should a dog be worn out in ten or twelve years, its limbs be stiff, its sight and hearing impaired, its intellect obtuse, and senile changes be discoverable in its brain and elsewhere, when a parrot might take a century for the production of the same destructive changes? Why tissues of the same composition should wear out in one animal after ten revolutions of the earth when it took a hundred revolutions to destroy similar ones in another, was by no means apparent. In man, if the destructive and reproductive changes were normally counterbalanced, the ordinary duration of life is reached. If the balance were not kept, the destructive agencies might be in the ascendancy, and life be shortened. If any of the ordinary surroundings which are always exerting their influences upon us, as various kinds of air, food, moral and mental moods, were in any way noxious, they might in time tend to premature death; and if they should act in such a manner as to cause localized organic changes, we should style these changes disease. There could be little doubt that a large number of maladies in England, as gout, Bright's disease, etc., were induced by mere excesses or inequalities in a mode of life which was considered ordinarily correct. It should be one of our studies to consider the relations of the human race to the soil, and observe all the circumstances which centuries had induced to bring about this normal or healthy relation between them. We might then observe the effects of the concentration of some of the more untoward of the influences which ordinarily environ it, as well as inquire into the effects of transplantation into another country. It seemed that all the usual surroundings of life in civilized society, acting in undue proportion or in a more determined manner, induced a very large number of the diseases which we were called upon to treat.

In considering all these agencies, working for what we call evil and leading to destruction, we should not overlook an opposing law—that of reparation. Not only did we observe a production of living force in necessary association with a dissolution of material, but an ever-existing tendency toward the remaking of the injured tissues. We could scarcely think of a morbid change in the body which was not attended by another which has an opposite tendency. Every phthisical lung showing destruction of the tissue exhibited at the same time the attempt to limit the process and to save life by shutting off the escape of air from the lung or sealing the ulcerated blood-vessels.

Then, again, in considering the definition of disease, after having observed how large a number of maladies were produced by the influences of all our ordinary surroundings, we had to recognize those external causes of an extraordinary or specific character which prey upon the human frame, and often brought its machinery to an end. Now, if these causes were obviously parasitic, we were not witnessing so much the case of disease as the spectacle of one animal preying upon another. As regarded the parasite, it was pursuing its normal life-history, and as regards the patient or the host, he was simply being destroyed; the difference in his mode of death from that which would result from the onslaught of a wild animal, would consist merely in time. If a man fall a victim to the bite of a cobra, he was not said to die of disease; but the term was applicable if he died of glanders. There was this difference, however, in the latter case: the poison was not a natural one, even in the infecting animal. If, however, in these infectious diseases the morbific cause was an animal or vegetable organism, although microscopic, then we really had to deal with the operation of one living being acting upon another, and the so-called specific malady exhibited nothing more than the natural course of life of certain specific organisms. The term disease, according to the definition, was here again scarcely applicable.

All these abnormalities of the human organism, under whatever conditions they might arise, suggested that, as every branch of biological science was being studied in relation to the lower organizations and according to the law of evolution, so must pathology become the subject of a large field of inquiry, and be made to embrace the diseases of all animal and vegetable life. The comparison of disease in man and animals might throw much light upon its nature, and it was remarkable that so few persons had been stimulated to the work, by considering the long controversy which had taken place as to the relation between vaccinia and variola, or hydrophobia and rabies. A true human pathology should have its basis in comparative pathology. Here lay a mine of wealth but little worked. As at the present time every structure and function of the human body was being studied in reference to its antecedents in the lower animals, so there could be no doubt that the various morbid changes to which it was liable might be also profitably discussed in reference to similar actions in more simple forms of life. The truth of this had been clearly seen by philosophers who had no special acquaintance with our department of science. Thus, Buckle, in his "History of Civilization in England," said: "The best physiologists distinctly recognize that the basis of their science must include not only the animals below man, but also the entire vegetable kingdom, and that without this commanding survey of the whole realm of organic nature we cannot possibly understand even human physiology, still less general physiology. The pathologists, on the other hand, are so much in arrear, that the diseases of the lower animals rarely form parts of their plan, while the diseases of plants are almost entirely neglected, although it is certain that, until all these have been studied and some steps taken to generalize them, every pathological condition will be eminently empirical on account of the narrowness of the field from which it is collected." This was almost as true now as when written several years ago; but the speaker was pleased to think that his countryman, Sir James Paget, had already removed the slur upon our scientific procedure by his lecture on "Elemental Pathology," in which he showed the importance of observing the resemblances between the changes in the various tissues of man and the vegetable world, and also the deductions to be drawn therefrom.

Again, if the specific diseases were due to organisms, and the hypothetical *contagium vivum* was a reality, it must be subject to the same laws as other organic matter; and if the doctrine of evolution were true, it must have numerous relations with families of its own kind, and perhaps with others which were now obsolete. This idea had occurred to the minds of Airy, Thorne, and several medical men in Great Britain, and it would no doubt further fructify in their hands.

A highly contagious disease prevailing in a particular locality might be exhibiting the differentiation of some more simple, less virulent, and widely spread disorder. For example, a slightly contagious epidemic sore throat might, in course of time, develop into a more virulent one until it culminated in diphtheria; and if this disease were due to an organism, the latter might have found a more genial soil for its development, or be altered by propagation and time, so that new properties might at last be added to it. There might be a progressive development of infectiveness. Then, again, the doctrine of natural selection might obtain in the fact of some specific diseases remaining among us, while others had become obsolete. The same law, too, if allowed its full operation, might tend still more than it does to the subjugation of many hereditary diseases; for as these appear in youth, and often cause death, they would fade away by a process of self-destruction. As regarded the specific diseases, it was evident that the most susceptible persons would be struck out by the poison, and the least susceptible remain, so that the poison would be modified in its virulence. We witnessed this fact in the more moderate characters of the exanthemata in all civilized nations, in comparison with the more profound effects produced by them in nations where the diseases had been hitherto unknown, as, for example, the fatality in the Pacific islands of our comparatively mild British measles.

Besides the maladies which were induced by the evil influences of our ordinary surroundings, and those due to specific causes just named, there was a class of diseases styled new-growths, which took a very large share in adding to man's mortality. The advance made in our knowledge of these structures was very considerable, and was still rapidly progressing toward a determination of their origin and the discovery of their relation to the normal tissues. These investigations were assisting us in discarding some of the older notions regarding their constitutional and malignant nature, and proving that many were accidental in their origin, and therefore might possibly be averted.

---

## SECTION ON MENTAL DISEASES.

### First Day—Wednesday, August 3d.

### C. Lockhart Robertson, M.D., Cantab, F.R.C.P., President, in the Chair.

### THE CURE AND TREATMENT OF THE INSANE IN ENGLAND.

After an appropriate welcome to the members, the President stated, by virtue of his official position as senior physician to the Lord Chancellor, the guardian of lunatics, that he occupied the presidential chair of the section. He offered no excuse for the choice of his subject, inasmuch as it was one which, from a political point of view, interested every alienist.

The number of the insane in England of whom there was official cognizance was about 71,000, being in the ratio of 27.9 per 10,000, or 1 in 350 of the population. Of these, no less than 63,500 were paupers chargeable to the rates and maintained at the cost of the community. The remaining 7,600 are private patients, whose means vary from £50 to £50,000 a year, much the larger number being nearer £50—for insanity necessarily tends, by arresting the power of production, to the impoverishment of its subjects. Thus, of the total of the insane in England, 90 per cent. were paupers maintained at the public cost, and 10 per cent. only were kept by their own resources.

In England 61.5 per cent. of the lunacy of the country was maintained in the public asylums. In Scotland it reached 75.6 per cent., while on the other hand the proportion of patients in private asylums is 6.5 per cent. in England as against 1.6 in Scotland. In England 9 per cent. only of all lunatics were placed for care in private dwellings; in Scotland the proportion rises to 15.8. In England there were 23 per cent. in workhouses; in Scotland there were only 7 per cent. In England 43 per cent. of the private patients were in private asylums, while in Scotland the proportion was 9.5 only. The public asylums, on the other hand, had 84 of the Scotch private patients under treatment as against 49 in England. In England, owing to the traditional preference of the Court of Chancery for private dwellings for the care of its wards, the proportion of patients so placed stood as 8 to 6.5 in Scotland, while with pauper lunatics these figures were reversed, the proportion in England being 9.4 as contrasted with 17.8 in Scotland. There were 43,700 patients in the public asylums of England, or 60.5 per cent. of the whole lunacy of the country. Of these, 40,000 were pauper lunatics, and 3,700 were private patients. The former were maintained in the county and borough asylums, the latter were divided between these and the registered lunatic hospitals.

The county and borough asylums of England, sixty in number, contained forty thousand beds, varying from two thousand to two hundred and fifty. They had been built and were administered under the provisions of the Lunacy Act of 1845. The average cost per bed had been under £200; the weekly maintenance of each patient was 10*s.*, to which should be added the interest on the cost of construction and the yearly repairs of the asylum, which were borne by the county rate, bringing the yearly cost for each pauper lunatic maintained in the county asylums to nearly £40.

The government of the English county asylums was entrusted by the Lunacy Act, 1845, to a committee of the justices of the peace, under the control of the Secretary of State for the Home Department. The administration was in the hands of the resident medical superintendent. A yearly inspection of the asylum was made by the Commissioners in Lunacy, and a yearly medical and financial report is presented by the committee and medical superintendent to the quarter sessions, and published.

The proportion of cures (discharged recovered) in the county and borough asylums in the last decennium, 1870–80, was 40.28 per cent. on the admissions, and the mortality 10.59 on the mean population. In Scotland, during the same period, the recoveries were 41.6, and the deaths 8. The only private patients admissible under the statute were those bordering on pauperism, and whom the law required as to classification and diet, clothing, etc., to be treated as the paupers. Herein the English

county asylums differed from those on the continent of Europe and in America, where alike, and he thought most wisely, special and often excellent provision existed for the care and treatment of private patients. At the public asylums near Rouen, at Rome, at Munich, and at Utica, in the United States, he had seen extremely good accommodation provided for private patients.

Besides the county asylums for the insane poor, there were in England fifteen lunatic hospitals, including the idiot asylums at Earlswood and Lancaster, where the principle of hospital treatment followed in the county asylums was applied to the insane of the upper and middle class with the most satisfactory results. These asylums had nearly 3,000 beds, and the average weekly cost of maintenance was £1 10*s.*, or, including the fabric account, £1 15*s.*

There were 3,400, or 43 per cent., of the private patients in England confined in private asylums, of whom 1,850, or 54 per cent., are in the thirty-five metropolitan licensed houses which are under the sole control and direction of the Commissioners in Lunacy, who diligently visit them six times a year. The remaining 1,550, or 4.6 per cent., are in the sixty-one provincial licensed houses which are under the jurisdiction of the justices in quarter sessions, but are inspected twice a year by the Lunacy Commissioners. The distinguished speaker concluded by an analysis of the requirements of the English lunacy law.

## SECTION ON DISEASES OF THE EAR.

W. B. Dalby, M.D., F.R.C.S., President, in the Chair.

Dr. Dalby, after expressing his gratification in meeting so many distinguished otologists, remarked:

In comparison with some other sections, the subjects selected for discussion, at first sight perhaps appear to be very few, but this arrangement has not been decided upon without due consideration and with a very distinct purpose.

The pathology of certain diseases of the ear may be said to be established, and their successful treatment is, without doubt, conducted by all of us upon very much the same routine.

There are others upon the pathology of which very different views are held, and in regard to whose treatment the most varied methods are now advocated and practised. When I say that amongst the latter class especial prominence should be given to the so-termed proliferous catarrh of the tympanum, its treatment generally, and the several operations which have been devised and practised for its relief, I feel sure that this statement will receive general assent.

I regard, therefore, the present occasion as affording a most unusually favorable opportunity for a thorough discussion upon all points connected with this matter, and the first subject upon the programme, viz., "The Value of Operations in which the Tympanic Membrane is Incised," includes all the debatable ground in connection with it.

Patients with this affection (certainly one of the most common diseases of the ear) are every day coming under the observation of aural surgeons, and it must be acknowledged that from the capitals of Europe and from the United States the views and practice of most eminent authorities, whether as regards general treatment or operative proceedings, are of the most different character, and often opposed to one another even in principle. This extreme divergence of opinion is of itself enough to indicate the difficulties which surround the subject.

I may perhaps be allowed to say that the position which operations upon the tympanic membrane occupies in surgery at the present time is of a somewhat uncertain and indefinite nature.

It is well known that many surgeons never make an incision into the membrane; that others, in their practice, strictly limit this procedure to those cases of acute inflammation of the tympanum in which there is tolerably conclusive evidence of the existence of pus. A third division, and this includes a very large proportion of those who attend to ear affections, make use of an incision, not only for the evacuation of pus, but also of mucus in a more or less fluid state from the tympanic cavity. In the fourth division must be placed those who, to the indications already named, add, as requiring one of the several forms of operation on the membrane, cases in which the tympanum has been the seat either of proliferous catarrh or of inflammation which has left the membrane connected to the ossicles, or the wall of the tympanum by adhesions. Lastly, we come to the division of the tensor tympani muscle. Without expressing any opinion on this subject, it may be said that, for whatever class of cases it may be practised, it can hardly be declared to take rank amongst those operations in surgery as one which, in consequence of its results, has received the recognition that is (and must be) accorded to every surgical proceeding worthy of universal adoption. It cannot, for example, in the present state of its history, bear comparison with a somewhat analogous operation in the department of ophthalmology —viz., iridectomy; and whatever position it may eventually occupy, it would be hardly too venturesome to predict for it a similarly brilliant future, if the anticipations which were formed by those who introduced and practised it had been even in a measure realized. What is the precise place which it holds at present, in the opinion of those well qualified to judge of its merits, we shall hope to hear before this session has concluded its discussions. We may, I think, fairly presume that the object which is sought to be attained from all operations which include incision of the membrane is of a twofold character, viz., the evacuation of the products of inflammation, or the relief of tension, and there are probably no surgeons of experience amongst us who have not some time during their career performed various operations with these principles in view. If a general expression of opinion on the respective merits and demerits of each and every operation on the membrane is extracted at this meeting, such as may serve as a guide to those members of our profession who are devoting their energies to the study of diseases of the ear, the interests of surgery will have been well served, and I sincerely trust that this may be the result of our deliberations.

The next subject for discussion, "Morbid Growths within the Ear," not only includes the origin, nature, and treatment of bony enlargements and exostoses in the external meatus, of polypus from whatever part arising, of myxoma, sarcoma, and cancer, but also the treatment of perforations of the membrane, inasmuch as this is a very constant accompaniment and exciting cause of these growths.

Probably no portion of the body so well as the ear could be selected to illustrate the doctrine in pathology which teaches us that a local irritation must precede a heterologous or homologous formation. To take the last-named examples of myxomatous,

sarcomatous, and cancerous growths. Certainly in none of the cases which I have myself seen, altogether three in number, or which within my knowledge have been recorded by other observers, has malignant growth affected the ear, unless it has been preceded for a considerable period by a purulent discharge secreted from the lining membrane of the tympanic cavity. The same rule held good in the only case in which I met with a round-celled sarcoma in the ear. A similar law will, I think, be always found to obtain when myxomatous tumors are found in this position. We all know how very generally every form of polypus is but the sequence of a perforation; and even when a polypus takes its origin from the external canal, a local irritation represented by a circumscribed inflammation, which involves the periosteum of the canal, has existed previously. In the case, too, of multiple bony enlargements of the canal, although very often it is not easy to point to a local irritation, the history of a perforation of many years' standing may not unfrequently be extracted from the patient, so that it is fair to infer that the passage of a purulent discharge over the surface of the canal has been the direct cause of the so-called exostosis. In order to show the extreme probability of the truth of this explanation, we must fall back upon our personal experiences of cases. On five occasions I have attended patients with perforation of the membrane, who have been dismissed, and have presented themselves between two and three years later with multiple enlargements of bone almost completely blocking up the canal. Another point, which also bears out the theory of a local cause to these growths, is one which I have constantly observed (and it has been recorded by others). It is that when the enlargements are found in both canals, the patients have been much addicted to sea-bathing.

The third subject on the list, "The Loss of Hearing where the External and Middle Ears are Healthy," embraces a very large proportion of the conditions under which the hearing is defective, whilst it is at the same time associated with subjective nervous symptoms. In this category will come syphilitic disease (inherited and constitutional) of the nervous structures, that very large class of cases to which, for want of a better name, and apparently for no other reason, the term Ménière's disease has been applied; a subdivision of this class, in the contemplation of which no one who has had a large experience of ear diseases can fail to be struck with the intimate relation which exists between the auditory and pneumogastric nerves. Cases of extreme deafness and perfect hearing alternating, without any explainable reason so far as an examination can detect. Those instances in which a permanent or temporary loss of hearing is without doubt primarily due to emotional influences form a most interesting and distinct group in themselves. This is not an occasion on which I would venture to occupy your time by the relation of cases, but I may be allowed to mention by way of illustration that I have known the hearing in apparently healthy subjects to be almost completely lost on the witnessing a sudden death of a near relative; on several occasions immediately upon the receipt of news of a painful nature; in the case of women, upon the fright produced by a cry of fire, or an alarm of burglars in the house; at the witnessing of the terrible sight of a man cutting his throat; once on the receipt of great good fortune which had not been anticipated. On each of these occasions the hearing power of the patient was always perfectly good up to the time of the catastrophe, and immediately afterward the deafness was intense, so that the change in all probability was almost instantaneous. In passing, I suggested as a possible, though imperfect and incomplete explanation, that in the cases referred to a sudden hyperæmia in some portion of the brain, or perhaps in the medulla at the origin of the auditory nerve, may account for a phenomenon which we are not at present in a position to explain. In truth, because we cannot actually define the lesion, or even its position, it is none the less certain that a local origin must exist. We have also to consider the unmanageable subject and too often unmanageable symptom of tinnitus; the sudden and total loss of hearing consequent upon mumps, diphtheria, and some other acute diseases; the loss of certain ranges of notes, whilst other sounds are normally heard. The list might be readily extended, but it is only necessary to mention what I have done to show that there is no dearth of material for our deliberations.

In many nervous diseases which come under the observation of physicians, a certain train of symptoms is met with; at the same time the actual lesion, or sometimes even the position of the lesion, is uncertain. The diseases are, however, quite familiar to us all, and we apply the same name to them. Amongst aural surgeons I am sure that mental notes are often taken, by the help of which, if they received expression, the nervous diseases of the auditory apparatus would be sorted into groups—nameless, perhaps, but none the less suggestive of the probable termination of the cases, and rich in facts that might serve as a guide to future observers. That such notes, derived from the experience of years, may be laid before us when the third selected subject is under discussion, I have great hopes. I purposely forbear to refer to any of the eminent men whose names are connected with the various diseases I have mentioned by suggested treatment, by the operations which they have introduced, by their valuable investigations and observations. They are perfectly familiar to all the members of this section, and it would be difficult as well as invidious to allude to any without mentioning the names of many of the distinguished visitors whom we have the good fortune to meet to-day.

## SECTION ON DISEASES OF CHILDREN.

### First Day—Wednesday, August 3d.

### Charles West, M.D., President, in the Chair.

#### PROGRESS IN THE STUDY OF INFANTILE DISEASES.

The President, after expressing his deep sense of the honor conferred upon him, proceeded to give a cursory sketch of the progress of the study of infantile diseases during the past thirty years. He said:

Thirty years ago, throughout the whole of England and America, there was not a single hospital set apart for children. It was but rarely that one saw these little waifs and strays, in the wards of our general hospitals, for the maxim, "De minimis non curat lex," held good in medicine as in law. Germany, too, was in but little better case, and one was forced to go to Paris to study on a large scale those diseases which men like Guersant, and Blache, and Baron, and Trousseau, and Rogers investigated with untiring zeal, and, in spite of hospital arrangements most painfully defective, strove to cure. We all know how this is altered now. In London there are

six separate children's hospitals, each, I believe, with its convalescent branch; and children's wards are to be found in every one of the large London hospitals. There are special children's hospitals in every large town in England. America and Germany have followed this example, and almost everywhere throughout Europe the opportunities for the study of the diseases of children are almost as numerous as for the diseases of adults.

Nor has this wide field been without abundant husbandmen to till it, and we may count with satisfaction the fruits of their labors.

The vague phraseology which served for years to conceal our ignorance even from ourselves, has been to a great degree done away with. We talk no longer of worm fever, remittent fever, gastric fever, and so on; for under these various names we recognize the one disease, typhoid fever, varying in severity, but marked always by its own characteristic symptoms. Half a page in a hand-book was all that was to be found, thirty years ago, concerning heart-disease in childhood; while at the present day the frequency of heart-disease has been fully recognized, and it has been studied with as minute a care in the child as in the adult. The various inflammations of the respiratory organs are no longer looked on as a whole, but each is referred to its proper class, and we distinguish lobar and lobular pneumonia, bronchitis and capillary bronchitis, and assign to each its proper place and its characteristic symptoms. Nor have our therapeutics lagged behind. I remember the hesitation with which, some years ago, my dear friend and master, the late Dr. Latham, decided on tapping the chest of a boy eight years of age, who was received into St. Bartholomew's Hospital on account of a pleurisy which had terminated in empyema; and the delight, the wonderment almost, with which we regarded the successful issue of the operation in a child so young. A few months ago, I communicated to the Medical Society of Nice the particulars of fifty cases in my own practice where paracentesis of the chest had been performed at my desire, and several of you, gentlemen, could relate as many cases as mine. That once almost unrecognized disease, diphtheria, has been studied with the greatest care, its relation to membranous croup has been investigated, the close connection of the two has been demonstrated. I, for my part, would not hesitate to say their absolute identity has been established. Much light has been thrown on the various diseases of the nervous system. That once enigmatical affection, the so-called essential paralysis of infancy and childhood, has been shown (in the first instance by the researches of my friend, M. Roget, and his able coadjutor, M. Damaschino) to be due to an acute inflammatory softening of the gray matter of the anterior columns of the spinal cord; and twenty-five recorded observations since that time attest the truth of their discovery. Though strictly speaking, perhaps, not a disease of the nervous system, the pseudo-hypertrophic muscular paralysis of Duchenne claims mention here as a new and important addition to our knowledge of the pathology of early life.

I fear to weary you by further enumeration, else it would not be difficult to increase largely the instances of new and most important knowledge added to our stores since my student days. In estimating the value of their gains, too, it must not be forgotten that each truth established means an error exploded; so much base metal, so much counterfeit coin withdrawn from circulation, or, to put it differently, so much sterling gold substituted for inconvertible paper money. In this progress surgery has everywhere borne a large part. The treatment of hip-disease, the excision of scrofulous joints, the new modes of treatment of spinal curvature—some, indeed, still on their trial—the operation for the cure of genu valgum, which one cannot mention without a fresh tribute of thanks to Joseph Lister, who in this instance has rendered a proceeding safe and salutary from which but a few years since the common sense of the surgeon would have recoiled—are so many fresh instances of progress made during a period of little more than the half of my professional life. I take it, however, that the great use of meetings such as the present is to take stock far less of what we know than of what we do not know, or know at best but imperfectly. A few of these problems have been submitted to you in the list of subjects for discussion. To some it is probable that the combined experience of so many and such distinguished men as are here present may furnish definite and conclusive answers. Other questions are introduced in the hope of gaining fresh information on points concerning which our knowledge is fragmentary; while there are many other problems still unsolved, on which it is hoped that fresh light will be thrown during the time of our meeting here.

And now, with your permission, I will conclude with an old apologue, which tells how when the fabled Arabian bird renewed each hundred years its vigor and eternal youth, the birds of the air all helped to build its nest. The eagle and the wren contributed alike to this labor of love and duty; each brought what he could, nor ceased till the task was done. And surely science and art—especially our science and art—are old and new: renewing day by day; burning, by a voluntary self-cremation, old theories, half facts, hasty conclusions, and substituting more accurate observations, truer inferences, more solid judgments. To this great end we may all do something; but, labor as we may, our task will never be finished, for not once in a hundred years, as the fable runs, but every day and all day long, the process goes on: a daily death, a daily renewal, as in our body's growth—a death of error, a development of truth.

---

THE BROMIDES IN SEA-SICKNESS.—The large claims made by Dr. G. M. Beard for bromization as a specific against sea-sickness, have excited much comment. Experience, so far, seems to show that the drug undoubtedly does prevent sea-sickness in many cases. The claim, however, that it is as sure a preventive as vaccination is of small-pox, is rash, and as yet by no means substantiated.

A fatal accident, probably from the use of bromides, was reported not long ago. It occurred to a physician, Dr. Reed, of Hartford, who was treating himself upon the plan of bromization in order to prevent sea-sickness. He took, it is reported, *eleven ounces* of the bromide of sodium. Temporary insanity was produced, and the patient threw himself overboard, and was drowned.

Another case is related, in which the bromides were given to a child for the same purpose. The result was a temporary impairment of vision. The amount of the drug taken is not known.

A third case, showing the accumulative effect of the drug, has been reported.

# Reports of Societies.

## THE AMERICAN OPHTHALMOLOGICAL SOCIETY.

*Seventeenth Annual Meeting, held in Newport, R. I., July 27 and 28, 1881.*

WEDNESDAY, JULY 27TH—FIRST DAY—MORNING SESSION.

THE society met in the Masonic Building, and was called to order at 10 A.M. by the President, DR. H. D. NOYES, of New York.

The President made a few congratulatory remarks, after which he appointed as *Business Committee*, Drs. Hasket Derby, of Boston; W. H. Carmalt, of New Haven, Conn.; John Green, of St. Louis; G. C. Harlan, of Philadelphia; and A. Mathewson, of Brooklyn.

As *Committee on Bulletin*, he appointed Drs. George Strawbridge, of Philadelphia; and H. G. Miller, of Providence, R. I.; and as *Auditing Committee*, Dr. O. F. Wadsworth, of Boston.

NEW MEMBERS.

Drs. H. W. Bradford, of Boston; William F. Mittendorf, of New York; S. C. Ayres, of Cincinnati; and J. B. Worrell, of Terre Haute, were elected members.

*The Committee on Bulletin* announced as the first paper, one

ON THE ADMINISTRATION OF ANÆSTHETICS IN BRIGHT'S DISEASE OF THE KIDNEYS, AND ON SOME CASES OF SUDDEN DEATH AFTER CATARACT OPERATIONS,

by DR. WILLIAM F. NORRIS, of Philadelphia.

The paper contained the histories of two cases in which death occurred after the extraction of cataract. They had three features in common: 1st, both patients were etherized; 2d, both patients died comatose; and 3d, careful autopsical examinations revealed no organic lesions except those of Bright's disease of the kidneys.

The first patient was a child, five months old, which was operated upon for congenital cataract. It recovered consciousness, but died a few hours subsequently. There was intense congestion, cloudy swelling and fatty degeneration, most marked in the cortical portion of the kidneys. There was no history of hereditary disease.

The second patient was a woman sixty-eight years old. She had gouty knuckles. The urine was not examined before the operation. A cataract was extracted from the right eye. She recovered from the anæsthetic readily. On the evening of the day following, the urine was somewhat diminished in quantity and loaded with urates. The patient was feverish. On the fourth day she sat up, and improvement continued until the ninth day, when her general symptoms began to be unfavorable; on the sixteenth day she became delirious; on the seventeenth day the urine was examined and found to contain albumen and fatty and granular casts, and it had a specific gravity of 1008. The patient died on the eighteenth day after the operation.

The kidneys showed marked congestion, increase of interstitial tissue, degeneration of the epithelium, and numerous casts in the tubules.

The next paper was read by DR. HASKET DERBY, of Boston, and entitled

ANÆSTHESIA AND NON-ANÆSTHESIA IN THE EXTRACTION OF SENILE CATARACT, WITH COMPARATIVE STATISTICS OF TWO HUNDRED CASES.

The lesion was hard, uncomplicated senile cataract. The comparison was between one hundred cases of that character in which the operation was performed with ether, and one hundred like cases in which it was performed without ether.

The average age of the patients operated upon with ether was $61\frac{7}{10}$; without ether $65\frac{8}{10}$.

There was loss of vitreous with ether in 14 cases; without ether in 9 cases. The duration of treatment with ether was $18\frac{3}{10}$ days; without ether $16\frac{5}{10}$ days. Secondary operations were performed in 22 of the patients primarily operated upon with ether, and 14 of those who had been operated upon without it. Success had followed; that is vision, $\frac{1}{10}$ or more, in 81 cases with ether, and 89 without.

Partial success, vision $\frac{1}{7}$ to $\frac{1}{60}$, in 8 cases with ether, and 9 without. There was reasonable prospect of success after a secondary operation in 2 cases with ether, and 1 without.

Total failure occurred in nine cases with ether, and 1 without.

Of those operated upon with ether, 91 recovered an appreciable amount of vision, and 99 of those operated upon without ether.

Von Graefe's operation was performed. A mixture of vaseline and eserine was applied before operating. The eyes were kept closed seven days after the operation. The assistance of the conscious patient in all the steps of the operation he regarded as highly desirable.

The general subjects, *The possible relation which might exist between the administration of ether and fatal results in cases of Bright's disease*, and *The influence of ether upon the success in cataract operation*, were then before the Society for discussion.

DR. MATHEWSON, of Brooklyn, gave negative evidence upon the first subject.

DR. ROOSA, of New York, thought that too early opening of the eye after cataract extraction was deleterious; but, with regard to extracting cataracts without anæsthetics, it seemed to him that Boston patients had been much better trained than those which he had met either in Vermont or New York. He felt much safer with anæsthesia, and would take the risk, even after Dr. Norris's excellent paper, believing that the dangers to the eye without it more than balanced the unfavorable results which might follow with it.

DR. STRAWBRIDGE, of Philadelphia, remarked that, in deciding whether or not ether should be used, the danger from the shock of the operation must not be overlooked. He had extracted cataract with ether only twice, and had not found any difficulty in performing the operation without anæsthesia.

DR. H. W. WILLIAMS, of Boston, thought that the advantages afforded by ether were positive and considerable. He agreed with Dr. Derby that the eye should be left alone for several days, except when symptoms supervened which warranted the conclusion that something was going wrong.

DR. CARMALT, of New Haven, cited two cases in which death occurred after extraction without anæsthetics. In one, death occurred within four hours; and in the other, several days after the operation. In the latter case there had been diabetes mellitus, but the patient had apparently been well for some

time. In the first case, that of a woman, fifty-five years old, death seemed to have occurred from shock, which perhaps would have been avoided by the use of an anæsthetic. There was hypertrophy of the left ventricle with a double murmur, although the patient had never had any symptoms of cardiac disease, and it was regarded as a contra-indication to the use of anæsthetics.

Dr. Norris believed that the action of ether in many cases of heart disease was beneficial rather than otherwise. But kidney disease had been recognized as a serious complication in any case which required a surgical operation.

The President had used ether where he knew kidney disease existed. He had not had a fatal result from the use of anæsthetics, although he had employed them in a very large number of cases. During the last year he had been accustomed to administer ether, and sometimes chloroform, to the production of primary anæsthesia when the first incision was made, and then the patient allowed to completely regain consciousness so that he could give his co-operation in the subsequent steps of the operation. On the whole, he gave anæsthetics for cataract operations less frequently than formerly.

The discussion was continued by Drs. O. F. Wadsworth, of Boston; J. S. Prout, of Brooklyn; B. J. Jeffries, of Boston; C. J. Kipp, of Newark, N. J.; and Dr. Derby. The use of anæsthetics in cataract operation was favored by a majority of those who discussed the question.

THE PECULIAR LOOK OF THE COLOR-BLIND

was the title of a paper read by Dr. B. Joy Jeffries, of Boston.

The peculiarity to which attention was directed was an "aimlessness of look," "a peculiar, dazed, half-anxious appearance of the eye," perhaps more marked in females than in males. No explanation for it was offered. It had been substantially described by Wilson.

Dr. W. S. Little, of Philadelphia, gave the history of a case of

PERSISTENT HYALOID ARTERY.

It was accompanied by an illustration. The condition was accidentally discovered with the ophthalmoscope while examining the eye of a boy six years of age. Dr. Little also reported four cases of

GLAUCOMA,

and in all of them there was a tendency to hereditary to the same, and the patients had hypermetropia and hemorrhoids. In all the cases the disease was bilateral.

The paper was discussed by the President, who cited two cases which sustained Priestly Smith's view regarding the essential pathology of glaucoma, namely, an exceedingly narrow circumlental space.

Dr. John Green, of St. Louis, then read a paper on

IRIDOTOMY, WITH DIVISION OF AN ANTERIOR SYNECHIA, BY THE USE OF WECKER'S PINCE-CISEAUX.

The patient was a child, seven years old. A wound, inflicted with a pen-knife, involved the cornea, iris, and lens. The operation for the synechia consisted in opening the cornea with a Graefe's knife, followed by the introduction of the scissors, and snipping it off close to Descemet's membrane. Recovery was good, and vision, practically nothing before, was raised to one-twentieth by the aid of a three inch convex lens.

Dr. George C. Harlan, of Philadelphia, reported

A CASE OF CONGENITAL PARALYSIS OF THE SIXTH AND SEVENTH NERVES ON BOTH SIDES.

The patient had never had diplopia. Dr. Harlan proposed to divide the internal recti muscles completely, and then remove a fold of conjunctival tissue from the outside of the eyeballs.

Dr. Francis B. Loring, of Washington, D. C., pointed out

A SOURCE OF DANGER IN THE EYE-GLASS FRAME AS COMMONLY MANUFACTURED.

The point of danger consisted of the small spike on the inner surface of the eye-glass frame, which in two of his cases had been driven into the eye. The remedy was to put the catch upon the outside of the frame.

Dr. S. Theobald, of Baltimore, reported a case in which useful vision was maintained through a number of years by the aid of

A TOTALLY DISLOCATED LENS.

The boy, twelve years of age, was extremely myopic, and the unusual convexity of the dislocated lens was believed to be its cause. Dr. Theobald regarded the case as unique.

The paper was discussed by Drs. Harlan, Noyes, and Williams, who had met with similar cases.

Dr. Hasket Derby, of Boston, exhibited Dr. H. W. Bradford's

ELECTRO-MAGNET,

which raised a bar four times its own weight. Remarks concerning the use of this, and Dr. Gruening's instrument, in the removal of foreign bodies from the eye, were made by Drs. Kipp, Jeffries, Noyes, and Prout, all of whom had used them successfully.

Dr. S. D. Risley, of Philadelphia, then read a paper on

THE COMPARATIVE VALUE OF THE MYDRIATICS IN OPHTHALMIC PRACTICE.

His conclusions were as follows:

*Duboisia* was used in comparison with atropia in 32 eyes; was found to be superior in 7, equal in 12, and inferior in 9.

*Homoatropia* was used in comparison with atropia in 70 eyes; was found to be superior in 17, and equal in 23.

*Homoatropia* was used in comparison with duboisia in 38 eyes; was found to be superior in 8, equal in 18, and inferior in 11.

*Hyoscyamine* was used in comparison with atropia in 29 eyes; was found to be superior in 4, equal in 13, and inferior in 10.

*Hyoscyamine* was used in comparison with duboisia in 5 eyes; was found to be superior in 4, equal in 1, and inferior in none.

*Hyoscyamine* was used in comparison with homoatropia in 4 eyes; was found to be superior in 1, equal in 1, in none inferior.

The paper was discussed by Drs. John Green, F. B. Loring, Theobald, Norris, Little, Roosa, Bartlett, Ayres, Wadsworth, and the President.

The society then adjourned, to meet at 7.30 P.M.

---

First Day—Evening Session.

The society was called to order at 8 P.M. by the Vice-President, Dr. William F. Norris, of Philadelphia.

The first paper was read by Dr. C. J. Kipp, of

Newark, N. J., and consisted of the histories of two cases of

SARCOMA OF THE CHOROID,

with peculiar clinical features. In one case the tension in both eyes was equal. In the other case the tension was not sufficiently increased to enable him to say that it was decidedly so. The cases showed that even when choroidal tumors nearly filled the eye, they did not always produce increased tension, and also that the retina was not necessarily detached.

The paper was discussed by Drs. John Green, J. F. Noyes, of Detroit, and the President, all of whom had seen choroidal tumors without detachment of the retina.

WHAT CONSTITUTES INSUFFICIENCY OF THE INTERNAL RECTI MUSCLES?

was the title of a paper read by DR. S. THEOBALD, of Baltimore.

The practical point in the paper was whether or not it was necessary to correct internal insufficiency amounting to only 8°, 10°, or 11°.

DR. WADSWORTH regarded 5° or 6° as unimportant ordinarily.

DR. ROOSA did not attach any very great importance to the symptom, whether the patient was asthenopic or not.

DR. JOHN GREEN had seldom used prismatic glasses in practice; and, when used, it was usually for the positive diplopia which existed.

DR. RISLEY had found lateral deviation very infrequently, and was surprised to learn that Dr. Theobald had met with it so frequently.

THE PRESIDENT was very positive that such a thing as latent insufficiency of muscles existed, and out of eighteen hundred cases he had set aside two hundred and fifty as having sufficient muscular asthenopia to cause notice, if not treatment. In some cases where the insufficiency had amounted to 8°, he had regarded it as worthy of note, and possibly there might be need of prisms.

The discussion was continued by Drs. R. H. Derby, Roosa, Wadsworth, Risley, Hay, Harlan, Kipp, Theobald, and Buller.

DR. S. D. RISLEY next read a paper on

WEAK EYES IN THE PUBLIC SCHOOLS IN PHILADELPHIA.

Among the conclusions reached were the following: that the emmetropic eye is the model or standard eye; that myopia commences in the primary classes with a low percentage, and steadily increases; that the percentage of increase is lower in the schools of Philadelphia than in the schools of Europe; that hypermetropic eyes were more numerous than the emmetropic and myopic combined; that there was an evident and close relation between acquired myopia and school-life, for which additional methods of examination were responsible to only a limited degree. The number of eyes examined was two thousand four hundred and twenty-two.

DR. CHARLES H. WILLIAMS, of Boston, gave the histories of two cases in which he

REMOVED STEEL CHIPS BY MEANS OF BRADFORD'S ELECTRO-MAGNET.

The society then adjourned, to meet at 9.30 A. M. on Thursday.

---

THURSDAY, JULY 8TH—SECOND DAY.

The society was called to order at 9.30 A.M. by THE PRESIDENT.

The first paper was read by DR. F. BULLER, of Montreal, in which was reported

A CASE OF SUDDEN AND COMPLETE LOSS OF VISION AFTER LARGE DOSES OF QUININE.

The diagnosis was acute retrobulbar neuritis. The patient was a puerperal woman who was threatened with septicæmia. While taking quinine in twenty-grain doses she suddenly and completely lost her vision. She recovered her usual health and strength after twenty-two months, with perfect central color-perception and vision, but total abolition of peripheral color-perception and vision.

DR. JOHN GREEN regarded the occurrence of such cases as very exceptional.

The paper was discussed by Drs. Roosa, Green, Risley, and Buller.

DR. JOHN GREEN then read a paper sent by DR. J. P. WORRELL, of Terra Haute, on

MARKED NARROWING OF THE FIELD, WITH DIMINISHED ACUITY OF VISION, FOLLOWING THE USE OF DUBOISIA, AND PRESUMABLY DUE TO THE USE OF THAT DRUG.

DR. GEORGE C. HARLAN, of Philadelphia, placed upon record

A CASE OF INTERMITTENT CONCOMITANT DIVERGENT STRABISMUS.

The intermission was of the tertian type, and suddenly broke up on the occurrence of the squint on the off-day, but the strabismus had been more or less apparent since.

DR. ROOSA reported a case of

CONCUSSION OF THE VITREOUS, CHOROID, AND RETINA, BY A BULLET.

The ball entered the body just over the lachrymal sac, went down over the nose, over the cheek, and lodged about the glenoid fossa. There was no loss of vision immediately after the injury.

DR. C. F. WADSWORTH, of Boston, then read a paper on

NEUROTOMY OF OPTIC AND CILIARY NERVES.

He gave a detailed history of fifteen cases. In none was there evidence of sympathetic trouble in the fellow eye. In none did the sensitiveness of the eye return. In all the cases in which there was vascularity of the cornea, there was some sensitiveness of the cornea shortly after the operation. The eyeball atrophied to a certain extent. Mobility of the eye was good in all the cases.

DR. BULLER had performed neurotomy in three cases with satisfactory results.

THE PRESIDENT had performed the operation, and in the majority of his cases it had been successful. Yet his own feeling had been that the operation was of doubtful propriety.

DR. JOHN GREEN, of St. Louis, presented his

OBSERVATIONS ON SOME THERAPEUTICAL APPLICATIONS OF PILOCARPINE.

He had used Merck's preparation, two grains to the ounce of water, and had seen good results in the treatment of photophobia and also strabismus. The pain produced by the drug was very much less than that caused by eserine.

DR. THEOBALD exhibited a set of his lachrymal probes, properly made by an instrument-maker at 79 North Howard street, Baltimore.

THE PRESIDENT remarked that he had a set made by Reynders, which served excellently.

ELECTRICITY FOR THE CURE OF CATARACT.

THE PRESIDENT reported a case which belonged to the group of cataracts said to have been cured by the use of electricity. The patient, a woman, aged seventy, had incipient cataract, which consisted of a few striæ with diffused turbidity of each lens, and the pupils were very small. At the time she began the use of electricity there was great haziness of all objects, and reading was almost impossible. After the lapse of time the diffused haziness cleared up. Vision, before the use of electricity, was $\frac{20}{70}$ in one eye, and $\frac{20}{100}$ in the other. Twenty months subsequently, after the cure had been effected, as it was said, her vision was $\frac{20}{100}$ in one eye, and $\frac{20}{100}$ in the other. Examination with the ophthalmoscope revealed evidence of chronic choroiditis. Twenty months previously he had noted slight choroidal change. The case, then, was at first one of subacute choroiditis with cataractal complication, and the condition of things which gave rise to hazy vision was haziness of the vitreous, which cleared up under the electrical and hygienic treatment which the patient received; but the striæ in the lenses and the diffused haziness remained unchanged.

THE PRESIDENT also reported a case of

PULSATING EXOPHTHALMOS

which he finally cured by ligating the anterior orbital vein at the spheno-maxillary fissure. He believed that it was a mild form of artero-venous aneurism, in which the carotid communicated with the cavernous sinus, and that the ligature gave rise to a thrombus, which cured the pulsating exophthalmos.

DRS. CARMALT and HARLAN also referred to pulsating orbital tumors.

SNELLEN'S CLAMP AS A FORCEPS.

DR. JOHN GREEN said he had used Snellen's clamp, making both blades alike, as a forceps to assist him in performing his operation for entropion.

THE PRESIDENT suggested, as a measure to prevent the pedicle of the flap from wrinkling, which was taken from the forehead in plastic operations to repair the waste of tissue in removing extensive

EPITHELIOMA OF THE INNER ANGLE OF THE ORBIT,

to cut away skin enough upon the nose to make a bed for the pedicle to lie in.

The following papers were read by title: "On the Clinical Resemblances Between Sound and Color;" "Bony Growth of the Conjunctiva;" "A Remarkable Case of Splenic Disease, with Retinitis Leucæmica," by E. G. Loring, M.D., of New York; "A Case of Pulsating Tumor of the Orbit," by H. S. Schell, M.D., of Philadelphia; "Cicatrices of the Face, Involving the Eyelids and Orbit, and the Means to be Adopted for Remedying the Defects which they Produce;" "Malignant Disease of the Bones of the Orbit and Face," by C. S. Bull, M.D., of New York. "Ulceration of the Cornea Relieved by the Removal of Cerumen from the Ears," by James A. Spalding, M.D., of Portland, Me.

After the election of officers for the ensuing year, the society adjourned, to meet at Lake George in 1882.

TORNADOES AS A CAUSE OF INSANITY.—Six of those who survived the terrible tornado at New Ulm, Minnesota, have become insane from the shock.—*Med. and Surg. Reporter.*

## THE AMERICAN OTOLOGICAL SOCIETY.

*Fourteenth Annual Meeting, held in Newport, R. I., July 26, 1881.*

MORNING SESSION.

THE Society met in the Masonic Building, and was called to order at 10.30 A. M., by the President, DR. J. ORNE GREEN, of Boston, who appointed as *Business Committee*, Drs. Roosa and Noyes of New York, and Prout of Brooklyn.

Nominations for membership were made as follows: Dr. Gorham Bacon, of New York; Dr. George C. Harlan, of Philadelphia; Dr. A. Alt, of St. Louis; and Dr. S. C. Ayers, of Cincinnati.

The following gentlemen were elected members: Drs. W. H. Carmalt, of New Haven, Conn.; F. B. Loring, of Washington, D. C.; S. B. St. John, of Hartford, Conn.; and R. A. Reeve, of Toronto, Canada.

Drs. Gorham Bacon and W. M. Carpenter, of New York, and U. H. Brown, of Syracuse, N. Y., were elected members by invitation.

The first paper was read by DR. S. THEOBALD, of Baltimore, entitled

SUGGESTIONS REGARDING THE TREATMENT OF SUPPURATIVE OTITIS.

DR. THEOBALD had used, with marked success, a powder composed of equal parts of boracic acid and oxide of zinc, introduced freely by insufflation. Its action was mild and non-irritating, and it could be used in the painful stage of otitis media.

DR. H. D. NOYES, of New York, had used, with special advantage, a powder composed of equal parts of tannin and boracic acid.

DR. SEXTON, of New York, had used boracic acid with good results in chronic cases, and more especially when it had been combined with twenty-five or fifty per cent. of calendula.

DR. KIPP, of Newark, N. J., did not use powders, because he regarded it as good surgery to give vent to accumulations of pus. He had used oxide of zinc and morphia with benefit in desquamative otitis.

DR. BURNETT, of Philadelphia, had used boracic acid, usually pure, with satisfactory results, but had applied only enough to cover the walls, and rather as a dryer in the latter stages of muco-purulent affections.

THE PRESIDENT had used boracic acid satisfactorily, and introduced it in large quantities. He asked what the action of the oxide of zinc was.

DR. THEOBALD regarded its action as mildly astringent.

THE PRESIDENT had used the oxide of zinc chiefly as a dilutor, and had always attributed its great value to its efficacy as a drying powder. The only impalpable powder of boracic acid which he had been able to obtain was Mawson's.

DR. JOHN GREEN, of St. Louis, had used oxide of zinc with positive advantage. He believed that it underwent changes in the discharges, so that a continuous supply of soluble oxide was furnished which rendered its action constant.

DR. BUCK thought that Reynders' powder-blower was more convenient than a quill. It was durable, and could be easily introduced into the meatus.

DR. SEXTON referred to a case in which the meatus was packed so full of boracic acid as to arrest the discharge. He cautioned patients to immediately cleanse the ear upon the development of pain after

the powder had been used, and he preferred to introduce the powder through a speculum.

Dr. D. B. St. John Roosa, of New York, then read a paper on

THE VALUE OF OPERATIONS IN WHICH THE TYMPANIC MEMBRANE IS INCISED.

He said that he had abandoned all the older operations, such as cutting off tendons, use of acids, incising the drumhead, etc., in cases of *chronic proliferous non-suppurative inflammations* (except where, perhaps, there were adhesions between an ossicle and the promontory, etc.), and there was no suspicion of retained mucus or other fluid in the tympanic cavity.

Paracentesis, for the most part, in acute and subacute cases, was as great an addition to our means of effecting cures as had ever been made.

Red and swollen as drumheads might be, however, the proper use of leeches saved the patients from the cutting operation in some cases.

When the operation was performed, he favored the small incision, and used a small knife. Gentleness must always be observed, and too early interference should be avoided.

A prolonged discussion followed, and was participated in by Drs. C. J. Blake, of Boston; A. H. Buck, of New York; C. J. Kipp, of Newark, N. J.; H. D. Noyes, of New York; J. S. Prout, of Brooklyn; C. H. Burnett, of Philadelphia; Samuel Sexton, of New York; E. W. Bartlett, of Milwaukee, Wis.; A. Mathewson, of Brooklyn; and S. Theobald, of Baltimore.

Dr. Roosa's general position concerning operative interference for the improvement of impaired sense of hearing in chronic non-suppurative otitis, was uniformly endorsed. A large majority favored paracentesis in acute cases, and a large majority, also, favored the small incision and early performance of the operation. By a large majority, also, the operation had been performed without the use of anæsthetics.

The variety of instruments used numbered eleven, and included needles, bayonet-points, hoe-shaped, pointed like a cataract-knife, etc.

Dr. Sexton was opposed, in acute cases, to general and free incision of the drumhead, and relied upon such remedies as the sulphide of calcium, tincture of aconite for subduing inflammative and controlling neuralgic pains. He had abandoned the use of leeches, believing them to be unnecessary and often detrimental.

THE TUNING-FORK IN DIAGNOSIS,

was the title of a paper read by Dr. D. B. St. John Roosa, of New York, and it contained the following propositions:

"I. If one ear be normal as to hearing-power, and a vibrating tuning-fork be placed upon the vertex or the teeth, if its sound be intensified in the ear whose hearing-power is diminished, there is disease of the external ear or middle ear, but no lesion of the labyrinth or nerve.

"II. If, under the same conditions of a sound ear on one side, while the hearing-power of the other is impaired, the tuning-fork be not heard better in the worse ear, even if the meatus be stopped by the finger or the like, there is disease of the labyrinth, the acoustic nerve, or brain.

"III. If the vibrating tuning-fork be heard better on the mastoid than when placed in front of the meatus, there is disease predominantly of the middle ear.

"IV. If the tuning-fork be heard better through the air than through the bones, there being impairment of hearing, the disease which gives rise to this symptom is situated in the brain, nerve, or labyrinth."

Dr. Blake, of Boston, said that Dr. Roosa's second proposition raised the question again of conduction of vibration, through fluids. The results of experiments which he had been making, but had not completed, thus far went to show that considerable impairment of the vibrations attended their transmissions through fluid in a solid or closed space. It was possible, therefore, to imagine a condition in which, as the result of intralabyrinthian pressure, the vibrations of the organ of Corti would be impaired.

The paper was also discussed by Dr. John Green, of St. Louis.

The President, Dr. J. Orne Green, of Boston, then read a paper entitled

REMOVAL OF A FOREIGN BODY BY DISARTICULATION OF THE AURICLE.

Dr. Green removed the bullet in three pieces, and in the manner indicated. The patient lived twelve days.

The paper was discussed by Drs. Roosa and Noyes.

---

Afternoon Session.

The society was called to order at 4 P.M. by The President.

The first paper was read by Dr. C. H. Burnett, and entitled

MALIGNANT GROWTH IN THE NASO-PHARYNX, WITH EARLY AURAL SYMPTOMS,

which was due to obstruction of the pharyngeal extremities of the Eustachian tubes. The patient was a physician, who ascribed the development of the primary disease to Turkish baths.

The paper was discussed by Dr. Roosa.

Dr. C. J. Kipp, of Newark, N. J., then read the history of a case of

EPITHELIOMA OF THE MIDDLE EAR.

It proceeded from a previous otorrhœa.

SELECTION OF TEST-WORDS ACCORDING TO THEIR LOGOGRAPHIC VALUE,

was the title of an oral communication made by Dr. C. J. Blake, of Boston. By logographic value was meant the intensity of tone produced by the amount of air expelled.

SUDDEN AND COMPLETE LOSS OF HEARING DURING AN ATTACK OF MUMPS,

was the title of a paper read by Dr. A. H. Buck, of New York.

The histories of two cases were given. The parotid region was equally affected in both, yet hearing was lost in only one ear in one case, and in both in the other.

The paper gave rise to a prolonged discussion concerning middle- and inner-ear disease, and was participated in by Drs. Burnett, the President, Roosa, Kipp, John Green, Prout, and Sexton. The opinions seemed to be somewhat diverse upon the point whether, in such cases, the primary lesion was in the inner or in the middle ear.

Dr. Buck then read a paper containing the history of a case of

SMALL VASCULAR TUMOR OF THE MEMBRANA TYMPANI.

Dr. Samuel Sexton exhibited a flexible Eustachian catheter (see Medical Record, vol. xx., p. 82).

Dr. Roosa called attention to Taylor's ear-douche, manufactured by Reynders, of New York.

Dr. Buck mentioned Reynders' ear-douche, especially serviceable in treating children.

After the election of officers, the society adjourned, to meet at 11.30 A.M. on the day previous to the annual meeting of the American Ophthalmological Society in 1882, and in the same place.

## Progress of Medical Science.

Dry Dressings with Powdered Salicylic Acid.—The good results obtained in the treatment of ulcers, wounds, etc., by the application of powdered iodoform, have led to a similar series of experiments with powdered salicylic acid, at the surgical clinic of Erlangen. The method, as described by Schmid, is very simple: The wound is first carefully cleansed and disinfected with a five per cent. solution of carbolic acid. Where practicable, sutures are applied and the closed wound covered with a layer of very finely pulverized salicylic acid, one-half centimetre high and sufficiently extensive to overlap the wound one centimetre in every direction. Excavated wounds, after being cleansed, are carefully plugged with acid, and then likewise powdered, and the whole protected by a piece of antiseptic gauze or salicylated cotton. Wounds thus treated secrete only a small amount of wound-serum, which coalesces with the dressing so as to form an adherent crust. No smell of decomposition manifests itself; on the contrary, several wounds of long standing were thoroughly deodorized by this method, after ordinary Listerian dressings had been ineffectually employed. At the same time the temperature of the patient, if elevated, sinks as much as 2° C. or more. As the dressing appears to promote a luxuriant growth of granulations, it is more applicable to excavated than to surface wounds.—*Deutsche Zeitschrift f. Chirurgie*, Bd. xiv.; *Allgem. med. Central-Zeitung*, June 8, 1881.

Iodoform Dressings in Tubercular Diseases of the Bones and Joints.—Following the recommendations of Mosetig-Moorhof (*Wiener med. Wochenschrift*, No. 43 et seq., 1880, and No. 13, 1881), iodoform has recently been given a thorough trial in Billroth's wards, with very excellent results. It was found to be powerfully antiseptic, and especially applicable to cases not adapted for the ordinary Listerian dressings, as in operations in the mouth, pharynx, rectum, etc. Under its influence, wounds secrete only a minimal amount of serous fluid, and heal rapidly and painlessly. There is no fever, and, what is more important, iodoform has no toxic effect on the system. The usual method of application adopted by Mikulicz is to plug the wound with powdered iodoform or iodoformized gauze, cover this with cotton, and finally with any kind of waterproof tissue. Mikulicz also employs sticks made of one part of iodoform to two parts of gelatine. He also uses an ethereal solution (1:5). The latter was injected directly into the tissues of a joint affected with fungous arthritis without fistulæ, and brought about complete subsidence of the disease. Fifteen injections of half a Pravaz syringeful at a time were made. The agent was also employed with great success in the treatment of diphtheritic and phagedenic ulcerations, giving almost immediate relief from pain, and hastening the development of healthy granulations.—*Tenth Congress of the Society of German Surgeons*, April, 1881.

Transplantation of Marrow.—The question whether, after fractures, the internal callus originates in loco, or as an ingrowth from the periosteal callus, has at length been decided in favor of the former theory, by experiments the results of which Paul Bruns has described in the "Proceedings of the Tenth Congress of German Surgeons." Bruns transplanted cylindrical pieces of marrow from the diaphysis of the tibia or femur, beneath the skin of other parts of the body, and found that, after a period of twelve to fourteen days, several points of ossification appeared in each graft, and finally (twenty to twenty-four days) coalesced so as to form bony plates. These experiments were successful in twelve out of nineteen instances, but never when the graft was transferred from one animal to another. Both types of ossification were noted, that is, the direct transformation of marrow into bone through the medium of osteoid substance, and the indirect form through the medium of cartilage. The active agents were principally the osteoblasts contained in the transplanted marrow, the other tissue-elements remaining passive. The newly formed bone possessed all the characteristics of true osseous tissues, but would probably in time disappear entirely from its abnormal situation, as continued investigation demonstrated a gradually increasing number of giant cells, whose function was supposed to be one of absorption.

Croupous Inflammation of Steno's Duct.—Under the above heading Stilling reports the case of a patient who, three years before, was suddenly attacked, while dining, with a swelling in the right cheek, which proved to be a distended and enlarged parotid gland. On the following day the patient, happening to squeeze the tumor firmly, spat out a small amount of a purulent, shreddy mass, which was immediately followed by a copious discharge of thin saliva, whereupon the swelling collapsed, and by the next morning had entirely disappeared. A similar swelling occurs every three to six months, but the same manœuvre causes its disappearance. Stilling believes that many cases of parotitis occurring during the course of infectious diseases, especially typhoid fever, are due to croupous inflammation of the lining membrane of Steno's duct, and consequent stenosis. For the relief of such swellings he advises the passage of a fine probe.—*Wiener medicin. Wochenschrift*, No. 19, 1881.

Tuberculosis of the Mammary Gland.—An authentic case of this exceedingly rare affection is reported by Le Dentu, in the *Revue de Chirurgie*, No. 1, 1881. The patient, a girl of twenty-two years, who had suffered from scrofulous diseases in her youth, was treated in February, 1879, for a chronic abscess of the left breast, which healed after incision and drainage. One year later the same breast became uniformly enlarged, and had to be removed by amputation. On examination it was found permeated with abscesses lined with fungous masses, and containing tubercles possessing all the characteristics of this neoplasm.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 7, 1881, to August 13, 1881.*

STERNBERG, GEO. M., Major and Surgeon. Relieved from duty in connection with the National Board of Health, to proceed from Baltimore, Md., to San Francisco, Cal., and report to Comdg.-General, Dept. of California, for assignment to duty. S. O., 182, A. G. O., Aug. 10, 1881.

CORSON, J. K., Capt. and Asst. Surgeon. The leave of absence granted him in S. O. 61, May 31, 1881, Dept. of Arizona, extended two months. S. O. 179, A. G. O., Aug. 6, 1881.

HALL, J. D., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to apply for three months' extension, to take effect on final adjournment of G. C. Martial, of which he is Judge Advocate. S. O. 141, Dept. of Dakota, Aug. 4, 1881.

SEMIG, B. G., Capt. and Asst. Surgeon. Granted leave of absence for six months, with permission to leave the Dept. of the Platte. S. O. 182, C. S., A. G. O.

PERLEY, H. O., Capt. and Asst. Surgeon. Granted leave of absence for four months. S. O. 178, A. G. O., Aug. 5, 1881.

WHITE, C. B., Major and Surgeon. Died at Wilton, Conn., Aug. 10, 1881.

## Medical Items and News.

VELULI IN SPECULO.—"The Nineteenth Century Seen Through a Speculum," is said to be the title of the memoirs of his time which M. Ricord has prepared for his final literary legacy. These memoirs are not to be published until thirty years after his death. "But," says the chronicler of the *Union Médicale*, when, to a select and friendly audience, he reads a few pages, "it is Rabelais, Brantome, and one of the stories of the amiable Queen of Navarre to which the hearer seems to be listening."

From which it may be inferred that the prospective memoirs are witty and nasty. It is a curious psychological fact, that as old age and impotency come on, the fondness for hearing and relating stories that are a little "off," not to say lewd, often increases.

A POST-MORTEM EXAMINATION ON PROFESSOR SKODA was made by Dr. Chiari. The brain was found to be normal; its weight was only forty-five ounces, which is somewhat below the average. The heart was hypertrophied, and the aortic valves were shrivelled, thickened, and calcified at the base, so as to be manifestly incompetent. The aorta was dilated and atheromatous. The coronary arteries atheromatous, calcified, and smaller than normal at their orifices. The rest of the body was normal or nearly so.

THE STATE BOARD OF HEALTH held a meeting at Niagara Falls on the 11th instant. Dr. Harris read a paper setting forth a proposition for a State plan of vaccination, with a view to the suppression of small-pox. A resolution was adopted recommending the establishment by the State of a vaccine farm. Dr. Smith, of New York, read a report of the conference held at Chicago on June 30th in regard to the introduction and spread of small-pox in the United States. The gist of the report was that immigrants should be inspected closely everywhere, as they are on trains at Buffalo. Resolutions were then adopted that the New York State Board of Health co-operate with the national, State, and local authorities for the prevention of the introduction of small-pox into this country by immigration. The Hon. Erastus Brooks called attention to the resolution of the board in regard to the unsanitary condition of the school-houses in the towns and villages of the State, and the urgent necessity of following this up until public attention became thoroughly awakened to the important relations of school architecture and hygienic conditions to the health of the children. The Committee on Public Buildings was empowered to employ expert aid in securing a complete reform of this shameful neglect of the people. The meeting then adjourned until the regular quarterly meeting in November, at Albany.

THE HEAT IN EUROPE has been intense the present season, and a high mortality rate has been the result. In London the thermometer has registered at times 97° in the shade. In Paris and other parts of France the temperature in July rose, on some days, to 98°, 100°, and even, in one place (Cape Beárn), to 104°.

MR. ERASMUS WILSON has been elected President of the Royal College of Surgeons. The English medical press growls because he is not a representative surgeon. He was elected, however, by a handsome majority.

THE PARIS HOSPITALS are so overcrowded, that in many wards hammocks have to be hung to accommodate the overflow. The prevailing diseases are fevers and small-pox. Paris has sixteen hospitals, with a total capacity of eight thousand three hundred and sixty-six beds. Besides these, there are numerous asylums, and three military hospitals which will accommodate two thousand patients. There is talk of building two new hospitals.

BIOLOGICAL STUDY.—Princeton College is to have a post-graduate course in biology, the step having been taken with the hearty co-operation of President McCosh and several members of the Board of Trustees. It will be established in connection with the Geological and Zoological Museums.

TRICHINÆ IN NEW ORLEANS.—At a meeting of the Sanitary Association in New Orleans, on August 11th, Dr. C. B. White reported that two thousand four hundred and eighty-four hogs had been examined by the microscope at the slaughter-house, and six hogs infected with trichinæ were found, all of which came by rail from St. Louis.

HOW YELLOW FEVER IS TREATED AT PANAMA.—Commenting upon the large number of deaths from yellow fever at Panama, a dispatch says: "It may interest physicians in the southern section of the United States to learn that the canal treatment for isthmus fever is: first, an emetic; second, a purgative; third, another emetic; fourth, another purgative, and so on. No quinine is administered. Is it to be wondered at that people die under such a system of treatment?

THE INCREASE OF INSANITY IN NEW YORK.—Dr. Eagan, Assistant Medical Superintendent of the Ward's Island Lunatic Asylum, has given some figures in regard to the increase of insanity in New York City. The number of patients at the Ward's

Island Asylum is increasing at the rate of one hundred a year. On January 1st there were 1,150 inmates; now there are 1,220, an increase of 70 in seven months. That is over discharges and deaths. During 1880 there were 436 admitted, 234 discharged, and 151 died. The increase in the number of patients in the asylum last year was 60, the smallest number in five years. It has already exceeded that number so far this year. A great many insane persons sent here are found to belong to other countries, and are sent there. Many come from the Emigrant Hospital. All immigrants who become insane before they are five years in the country are taken to the Emigrant Hospital, and when the term of five years has expired they are sent here. In this way the city is caring for many lunatics from Europe. In the Women's Asylum, on Blackwell's Island, there are between fourteen hundred and fifteen hundred patients.

A NEW DISINFECTANT.—A cheap and useful disinfectant is a solution of chloride of lead. It is inodorous, effective, and its cost very small. It may be prepared as follows: Take half a drachm of nitrate of lead and dissolve in a pint or more of boiling water. Dissolve two drachms of common salt in a pail or bucket of water, pour the two solutions together, and allow the sediment to subside. The clear supernatant fluid will be a saturated solution of chloride of lead. A cloth dipped in a solution of chloride of lead and hung up in a room will sweeten a fetid atmosphere instantaneously, or the solution thrown down a sink, water-closet, or drain, or over a heap of refuse, will produce a like result.

TREATMENT OF SUMMER CATARRH AND HAY FEVER.—Dr. John C. Thorowgood (*Lancet*) gives some useful hints on this subject. He first enumerates the usual remedies used as inhalants for relieving congestion and destroying the pollen-granules. These may answer when the attacks are light. But when the congestion and catarrh have extended down to the bronchi, and a true hay-asthma is produced, there are few remedies that surpass arsenic. This may be employed by vapor or by mouth. Nitrated paper cigarettes, each cigarette containing gr. ¼ of arseniate of soda, have proved very satisfactory. Where arsenic fails alone, the following will often succeed:

℞. Liquor potas. arsenit..... ♏. ij.
Potas. iodid..... gr. ij.
Liquor ammon..... ♏. v.
Aqua..... ʒ j.

M.—This to be taken three times a day.

Tincture of nux vomica and citrate of caffein are also remedies that are very often useful.

AN ANÆSTHETIC CAR.—A correspondent of the *British Medical Journal* gives the following description of Bert's anæsthetic car for giving nitrous oxide and compressed air. "I was at the St. Louis Hospital one morning; the car was there, and some operations were to be done in it. We—the patient, doctor, and his students—went into the car; the door, air-tight, was closed, and air forced into the car; in a few minutes my ears began to feel strange, and I was told to swallow, yawn, and blow my nose, which I did every few minutes, and so made the pressure equal on both sides of the drums of my ears. The patient laid himself down on the operating-table, and the anæsthetic agent was given him. He took it very quietly, did not struggle, and was soon insensible. Whilst he was unconscious, an epithelioma was removed from his lower lip; after the wound was sewn up, the compressed air was allowed to escape; the patient got up from the table, walked out of the car, and lay down on the grass; he complained of no headache nor nausea, but said he felt just as usual. We also were glad to escape from the car, on account of the heat, which was very intense. During the operation, all the assistants and the surgeons pulled off their coats and waistcoats, and yet they perspired very freely. The car is on wheels, and is carried about from hospital to hospital; the hospitals being under Government, the car is a public one, and is taken all over Paris."

THE AMBULANCE SYSTEM OF NEW YORK, having been commended as a model to Paris, is now being held up before the Londoners. Dr. B. Howard describes it fully in the *British Medical Journal*, and advocates its introduction by English municipal governments.

HOMES FOR MENTAL CONVALESCENTS.—A very excellent project has been started in London, under the auspices of Dr. Andrew Clark and others. It consists in the attempt to provide a home for patients just discharged from insane asylums. It is urged that many cures might be completed and confirmed in this way.

THE VALUE SET ON MEDICAL SERVICES.—The *Lancet* states that a club in Norwich pays its medical men six shillings a year ($1.50) for their services, which is at the rate of about two-pence a visit. This is even worse than in Richmond, Va., where, according to the *Southern Clinic*, physicians are paid seven cents by the city for vaccinating a child, which includes a visit and vaccinating, taking down the name of the patient, and a lot of other information; also a second visit to see what the results are, etc., all to be carefully reported in writing, and all for *seven cents*.

HONORS TO MEDICAL MEN.—Mr. William MacCormac has just been decorated by the King of Bavaria with the Ritterkreuz of the first-class—a military order of merit—for services in the war of 1870–71, a rather late recognition.

He has also been made Commander of the Order of Takodo, for services in the Turko-Servian war.

The Victoria Cross has been conferred upon Surgeon John Frederick M'Crea, for conspicuous bravery in the South African campaign.

DR. AGNEW ON THE COURSE AND LOCATION OF THE BULLET IN THE PRESIDENT'S BODY.—A long article appeared in the *Philadelphia Times* of last week, purporting to represent the views of Dr. Agnew on the President's wound. This brought out a card from Dr. Agnew, denying that he had ever given expression to the opinions published as his. He gives his views regarding the course of the bullet, and says:

"I am made to say that the precise location of the ball is either in the quadratus lumborum or the psoas magnus muscle. The precise location of the ball I have never professed to know. I did say that in my judgment the missile passed along the anterior face of the quadratus muscle, behind the kidney, and probably was lodged in the anterior part of the iliac fossa. I am represented as saying that the liver may have been bruised, but not lacerated, whereas I have invariably stated that, after studying the case, I was disposed to believe that the liver had

been lacerated, but not perforated; the laceration being produced by the rib at the time the latter was struck by the ball, a supposition which, if true, would account for a limited hemorrhage, answering to an area of percussion dulness present after the injury, and which has been slowly clearing up since."

In conclusion, Dr. Agnew says: "I cannot but feel that an omission was committed in not allowing me an opportunity to review the article in question before committing it to the wide circulation of the *Times*. It would at least have saved the necessity for two communications from one who, I assure you, does not seek public disputation. I may say, further, that the criticism to which the President's medical and surgical attendants have been subjected does not disturb their equanimity in the least. They have a responsible duty to perform. Nothing will be omitted, nothing knowingly committed, which in their judgment will endanger this valuable life, and, when the proper time arrives, they will submit the medical and surgical history of this remarkable injury to the profession, the only tribunal competent to pass an opinion on the conduct of the case."

THE COLOR-BLINDNESS LAW IN MASSACHUSETTS.—Dr. B. Joy Jeffreys writes us that the law regarding color blindness recently enacted by the Massachusetts Legislature, is not all that he worked for or wished, although it is better than nothing.

He also states that the law compels an examination for defective vision as well as for color-blindness.

LIFE INSURANCE AND OVERDOSING.—An important decision has recently been rendered by the Court of Appeals in the case of a Mr. Penfold, who died from an overdose of medicine. The medicine was prescribed by a physician in what was thought to be proper doses, and it was taken by Mr. Penfold in good faith; but it killed him. He was insured with a policy which said if he should "die by his own hand or act, voluntary or *otherwise*," the company should not be liable. The company refused to pay the policy; for, they said, he took the drug by his own hand, and that whether he did so voluntarily or not was unimportant. The decision was in favor of the right of the family to receive the money.

PROMOTING MEDICAL SCIENCE.—An Act amending an Act to promote medical science has passed the State Legislature and been signed by the Governor.

NEW HOSPITALS ON NORTH BROTHERS ISLAND.—Several members of the City Board of Health, the City Surveyor, and others, visited North Brothers Island last week for the purpose of locating the position of the new small-pox hospital. A spot on the northern portion of the island was finally selected. The building which it is proposed to erect on this site will be of brick, not over two stories high, and is intended exclusively for patients suffering from small-pox. It is also proposed to erect on the island hospitals for patients suffering from typhus fever, diphtheria, and other contagious diseases, but before this can be done portions of the ground will have to be graded and filled in, and a sea-wall built around the island. It is expected that the new small-pox hospital will be ready for occupancy by next spring.

LONGEVITY AMONG THE JEWS.—Dr. S. Gibbon, medical officer of health for the Holborn district, London, in his report for the last year, says that whatever may be the cause, there is no doubt that the Jew's life in London is, on the average, worth twice as many years as a Christian's. The Hebrews of the metropolis are notoriously exempt from tubercular and scrofula taint. It is very rare that one meets with pulmonary consumption among them. The medical officer of one of their large schools has remarked that their children do not die in anything like the same ratio as Gentile children; and in the district of Whitechapel the medical officer of Health has reported that on the north side of High Street, occupied by the Jews, the average death rate is twenty per thousand, while on the south side, occupied by English and Irish Gentiles, it is forty-three per thousand.

THE PLUMBERS AND PUBLIC HEALTH.—The plumbers are protesting against the enforcement of the registration act, because it compels them, they say, to submit plans to non-experts. The methods adopted by the Board of Health to carry out the law are as follows: Three forms have been drawn up. Two provide for the registration of master and journeyman plumbers and end with an agreement to comply with the rules established by the Board. The third blank is a notice of violation signed by the secretary of the board, with extracts from the new law. This will be sent to all plumbers doing faulty work in new buildings, when such fact is reported to the Board. It gives the plumber so many days to conform to the plan approved by the Board, and warns him of the penalty of non-compliance therewith.

THE NIGHT MEDICAL SERVICE.—END OF ITS FIRST YEAR.—The night medical service is now a year old. It seems to have been, on the whole, fairly successful, though there is much absurd talk in the daily press about its incalculable blessings. There have been, we are told, nearly 500 calls during the past twelve months. It is proposed now, by some enthusiasts, to establish a day medical service, paying a dollar fee to the physician called on.

HALF A BILLION CIGARETTES are smoked in this country annually. According to the revenue returns, only 9,000 of these are of first grade. The rest are, it is said, made of cheap paper, cheap tobacco, licorice, opium, etc.

Doubtless, many cigarette-smokers will protest against so severe a decision upon the quality of their weed. It is not impossible that cigarettes are registered as of low grade, in order to lighten the tax upon them. However, as this shows dishonesty in one direction, we can easily suspect it in another.

Cigarette-smoking is known to be locally more injurious than cigar or pipe-smoking. As to the constitutional effects, there are, we believe, no positive data. There is only a general impression that cigarettes are bad, and this for the especial reason that the smoke is, as a rule, inhaled.

PROFESSOR HUXLEY has been proposed as candidate for the position of Linacre Professor of Physiology at Oxford. No one could fill the position better. But it is objected that the distinguished naturalist already holds four salaried positions which bring him in five or six thousand dollars per annum, and the duties of which, presumably, might occupy his time.

OF ROYAL EXTRACTION.—Great has been the circumstances that surrounded the recent extraction of a troublesome tooth that belonged to the Shah of

Persia. His entire court was present to witness the awful spectacle, and during the same day he received no fewer than 3,000 ducats as presents of congratulation. It was a European dentist who performed the successful operation, and his grateful Majesty rewarded his skill with an even one hundred of the ducats.

Fresh Air for the Children.—The Floating Hospital of St. John's Guild is taking about a thousand children upon the river and bay three times a week.

The Seaside Retreat for children at Bath, L. I., which opened June 20th, has had over two hundred occupants ever since. Each child is allowed to stay a week.

The Sleeping "Hungarian," an account of whom was given in the Record some time ago by Dr. Beard, awakened on July 31st. He had been entirely unconscious for most of the time for one hundred and sixty-nine days. He has related his story, and it appears that he is not a Hungarian but a Pole. He had been out of work, and had not had enough to eat for several days. He said also that a short time before becoming unconscious a woman had given him an enormous dose of red pepper; he attributed his sleep in part to that. He remembered nothing of what had happened to him during his sleep. The case seems, as was asserted by Dr. Beard, to be one of trance-coma.

The *Ohio Medical Journal* is the title of the successor to the *Ohio Medical Recorder*, now defunct. The *Journal* is the organ of the State Medical Society. Its editor-in-chief is Dr. J. F. Baldwin. Dr. Baldwin is a spicy and able writer; we are glad that the new field before him is so promising.

How President Garfield's Room is Cooled.—The apparatus selected to cool the President's room is one devised by Mr. Jennings, of Baltimore. It consists of a cast-iron chamber, about ten feet long and three feet wide and three high, filled with vertical iron frames covered with cotton terry or Turkish toweling. These screens are placed half an inch apart, and represent some three thousand feet of cooling surface. Immediately over these vertical screens is placed a coil of inch iron pipe, the lower side of which is filled with fine perforations. Into a galvanized iron tank, holding one hundred gallons of water, is put finely granulated or shaved ice. This water is sprayed upon the sheets in the lower tank constantly. In each end of the iron chamber are openings thirteen inches square. To the outer end of this chamber is a pipe connecting with an outdoor air-conductor. To the opposite end is connected a similar pipe leading into an ice chamber at its top, and from the bottom of the same a pipe leads to a small exhaust fan, and from the fan the now cold and dry air is forced direct into the President's room through a flue some twenty feet in length. Air received at 99° temperature is supplied at the rate of 22,000 cubic feet per hour at the register in the President's room at 54°, and with the windows and doors open the temperature at the President's bed (twenty-five feet away) is maintained steadily at 75° day and night.

Growth and Weight of Children.—Some interesting studies with reference to the health and growth of children have been made by Dr. Boulton, of the Samaritan Hospital, London; instead of taking the average of a large number of children measured once, he adopted the plan of measuring a number of children of normal growth, brought up under average circumstances, many times, thus ascertaining their rate of increase. By this means, the annual rate of growth was found to vary between two and three inches for each child per year. Dr. Boulton believes that when a child varies more than a quarter of an inch annually, or when the increase of weight does not correspond with the weight within a margin of safety—put at seven pounds—then it is safe to conclude the child's diet is not good, or possibly some disease is lurking in his system. The curious fact appears that loss of weight always precedes the development of consumption.

Skull Measurements.—Professor Flower has published some further results of his researches with reference to the human skull. He states that the largest normal skull he has ever measured was as much as 2,075 cubic centimetres; the smallest, 960 cubic centimetres, this belonging to one of those peculiar people in the centre of Ceylon who are now nearly extinct. The largest average capacity of any human head he has measured is that of a race of long flat-headed people on the West Coast of Africa. The Laplanders and Esquimaux, though a very small people, have very large skulls, the latter giving an average measurement of 1,546; the English skull of the lower grades shows 1,542; the Japanese, 1,486; Chinese, 1,424; modern Italian, 1,475; ancient Egyptian, 1,464; Hindoos, 1,306.

Flatbush Hospital.—Dr. Harry O. Plympton, son of Prof. Plympton, of the Polytechnic Institute, has been appointed by the Commissioner of Charities and Correction, to the temporary Superintendency of the Flatbush Hospital, the office which Dr. D. L. Schenck recently resigned after seventeen years incumbency.

Lead-Poisoning from the use of Soda-water in Syphons.—It is often difficult to find out where lead could possibly have gotten into the system in cases that show marked evidences of chronic poisoning by that metal. It may be well to call to mind the case of a London physician, who traced the lead-poisoning in his own case to the use of soda-water in syphon bottles. The soda-water had taken up enough lead from the fittings of the bottles to poison him.

The Norristown Insane Asylum is to have a new wing for violent female patients. The asylum now holds 767 inmates.

Professor Haeckel has gone to Ceylon to pursue biological investigations.

Professor Pirogoff recently celebrated the fiftieth anniversary of his doctorate.

Well-water in Upper New York.—Dr. Waller has recently made a report to the City Board of Health on the character of the well-water in the Twenty-third and Twenty-fourth Wards. He states that "of twenty-six samples obtained from different sources, seven are very unsafe, six are unsafe, three are doubtful, and only ten can be looked upon as good. The samples all contained perceptible amounts of chlorides."

That Corner in Opium, of which there was much talk last winter, has fallen out, and opium is said to be selling now at from $4 to $4.25.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, August 27, 1881.

## THE INTERNATIONAL MEDICAL CONGRESS.

In the present issue we continue our full report of the International Medical Congress. We venture to say, that never before has a larger body of representative medical men assembled, and never before has so much sound and practical scientific work been crowded into a smaller space. Over thirty-two hundred members registered their names, and there were altogether one hundred and nineteen meetings of sections held. At these meetings, four hundred and sixty-four written and three hundred and sixty spoken communications were made, all of which had a more or less practical bearing upon medical progress. Large as was the number of papers presented, and extensive as was the variety of subjects discussed, we can form no idea of their value from a mere numerical point of view. When it is considered that on each topic there was one to speak with authority, and give the results of special and original work, we can hardly overrate the importance of the meeting, or justly estimate its influence upon the medical world at large.

The general sessions were occupied for the most part by the addresses, each of which was a masterpiece in its way. The orators were fully alive to the necessities of the occasion, and gave evidence of profound study and extensive research. The full abstracts which we have given of these, will enable our readers to judge for themselves concerning their respective merits. The presentation of medals of honor to each of the orators was a becoming tribute to the value of the services rendered by these gentlemen, and is a custom worthy of continuance.

The work in the sections was carried on with much system, and was, on the whole, of a very practical character. As had been anticipated, there was considerable confusion of tongues in some of the discussions, as each member was privileged to choose, out of the three official languages, the one with which he was most conversant. But, under the circumstances, it is difficult to see how this confusion could have been avoided.

Doubtless much was lost to such as did not understand the language of the speaker, and thus there was a want of that general appreciation of the value of the discussions on the part of the majority present which, to say the least, was to be deplored. Speaking on this subject, our esteemed contemporary, the *Dublin Medical Press and Circular*, rather humorously remarks: "It was, however, essential to permit freedom of choice in this respect to all, and, in spite of the curious result produced on those who patiently gazed in irresponsive wonder at first one and then another unintelligible expositor of foreign science and practice, it is impossible to regret the consequences, now that all is over.

"The student of the ludicrous might any day of the meeting have found in every section rich subject of amusement in the polyglot expression of interest successfully encouraged on the countenances of the respective presidents. The calm current of a debate would occasionally suffer from the occurrence of a little scene not to be disassociated from the circumstances; but, on the whole, matters worked smoothly along, with only occasional amusing *contretemps*."

The leading sections, those of medicine, surgery, obstetrics, and pathology, commanded the larger attendance, and the subjects discussed therein were correspondingly interesting and attractive. The doings of the surgical section were particularly remarkable for their bearing upon the subject of the treatment of disease. In this respect they were in striking contrast with other sections from which, perhaps more, in that line, might have been expected. In the Section on Medicine, for instance, there was an absence—almost complete—of papers bearing upon the treatment of disease, notwithstanding a special place had been retained in the programme for the discussion of that important subject. It is a noteworthy fact in this connection, that of the forty papers on the programme, no fewer than one-third dealt with diseases of the nervous system.

The sections on specialties were becomingly active, and especially was this the case with those on ophthalmology and laryngology.

The opportunities for the clinical demonstration of disease were not wanting, and during the week numerous interesting cases were exhibited in the museum. Dr. Duckworth showed a group of well-marked cases of true gout with uratic deposits, and Mr. Hutchinson, on the same day, showed several examples of the same disease and rheumatic arthritis, separately and in association. Messrs. Macnamara, Page, and Treves exhibited cases of joint-disease in tabes dorsalis. Mr. Page's case was

remarkable, for the joint-affection (which involved the foot) was present together with the Argyll-Robertson symptom and absence of knee-jerk, but without any ataxy. The patient had had severe pains in the limbs, and vomiting some time previously. Dr. Ord showed a number of cases illustrating myxœdema, in various stages of progress. Dr. Barlow exhibited a case of aphasia, with right brachial monoplegia, in a boy, the subject of hereditary syphilis; Dr. Sturge some cases of muscular atrophy; and Mr. Hutchinson two cases in which rupture of the brachial plexus was diagnosed. The appreciation which was shown for these exhibitions more than paid the different gentlemen for the pains they had taken to secure their material.

The social element of the meeting was a particularly distinguishing feature. A glance at the list of entertainments will convince any one that the conscientious respondent must have been sorely burdened by the kind intentions of his host. But everything was expected to be done on a large scale, and our British brethren would not have been true to their national instincts if they had neglected anything in that part of the programme.

---

PRESIDENT GARFIELD.

DESPITE the announcements that the condition of the President is hopeful and that he is making slight gains daily, it is quite evident that his chances for ultimate recovery are very poor indeed. The medical bulletins are worded with extreme caution, and on their face are calculated to give as little satisfaction to the public as is possible under the circumstances. With a laudable desire to inspire the greatest amount of hope in the favorable issue of the case, the surgeons in charge appear to be struggling against heavy odds. From a surgical point of view, the bulletins give no idea of the actual condition of the patient aside from the bare statements regarding the condition of the patient's pulse, respiration, and temperature, and the stereotyped assurances that there is a slight improvement since the previous note. In the aggregate this should mean a great deal, but that it does not is quite plain, when we strive to reconcile the statements of daily gain with a progressively weakened condition. Since our last report the irritability of the stomach has been in a measure controlled, but, as shown by the vomiting of Sunday last, this organ is liable at any moment to magnify itself into a serious complication. We can hardly expect otherwise, considering the extreme weakness of the patient and his greatly lowered power of vitality. The appearance of the parotid swelling, although serious enough in itself, is doubly so as indicating a generally depraved state of the blood, and a dangerous falling off of recuperative power. It does not seem likely, from all accounts, that the gland will suppurate; and the fear of abscess is apparently ill-founded. Nor is it strange that the swelling and induration show a tendency to remain stationary. This is what might be expected, considering the cause of the trouble and the depraved systemic condition which it occasions. As a local difficulty it is of no significance, except in so far as it gives rise to great personal discomfort by the mechanical obstruction to mastication, and by the annoying collection of viscid mucus in the fauces. Indirectly these conditions must affect the appetite, and in so far their existence is to be deplored, but the real cause for alarm is the progressive emaciation and slowly increasing weakness of the patient.

The wound is certainly not as well as it might be, considering the length of time that has elapsed since the receipt of the original injury. Under ordinary circumstances we should have expected it to have healed long ago. To be progressing favorably for so long a period, and with such a free and constant discharge of laudable pus, it is a matter of some surprise to learn that the track of the ball is still clear for a distance of twelve and one-half inches from the surface of the last incision. This would seem to indicate that the ball, wherever it may be, is not encysted, and is probably keeping up a deep-seated irritation. The length of the sinus is a matter for some concern, in view of the possible arrest of the discharge in any part of its course, and the consequent disastrous result upon the patient. These and other conditions tell against the chances of the sufferer in such a direct manner that his case becomes exceedingly critical, and the outlook quite unpromising. During the past week the pulse has ranged from 98 to 108, and the temperature from 88.3° F., to 99.4° F. Neither of these figures are high, but their steady persistence for several weeks explains the present alarming weakness of the patient, and their continuance day by day must diminish proportionately his chances for recovery.

---

A NEW DISCOVERY IN OBSTETRICS.—Dr. G. F. Laubach, of Papillon, Nebraska, sends us the following: "'Prescribing Extraordinary,' in *New Remedies* for August, reminds me of an obstetrical case to which I was called while in Minnesota, where the midwife (?) 'got stuck.' It was a case of twins, the first of which the midwife delivered dead, and failing to secure the second one, I was sent for, but upon my arrival she had the other one delivered, also dead. She called me to one side and showed me the fœtus, and turning it on its stomach, explained how she had proceeded. 'You see, the little thing got crosswise, with the back down, and I could not do anything, as I had no instruments; but the while they sent for you, the woman suffered so much that I asked for a pair of blacksmith's pinchers and grabbed the little thing by the spine and just pulled it out. It hurt the woman a good deal, but she feels better now. See where the pinchers grabbed the little thing, but it was dead, so it makes no difference.'

"Sure enough, right in the lumbar regions, she applied the 'forceps,' forced a locking, and a new discovery was made in obstetrics."

(Special Report for THE MEDICAL RECORD.)

## GENERAL SESSION.

SECOND DAY—THURSDAY, AUGUST 4TH.

### ADDRESS ON SCEPTICISM IN MEDICINE.

THE untimely death of Dr. Maurice Raynaud, caused the reading of his address to fall upon his friend Dr. Féréol. After a fitting tribute to the deceased, he proceeded with the address on "Scepticism in Medicine."

The author, Dr. Maurice Raynaud, did not propose to give the history of medical scepticism, for there had been in all ages, and apparently there always would be, sceptics. Scepticism was one of the attributes of the human mind, just as extreme credulity was another. In fact the preference was usually given to the former, but they both worked hand in hand toward the truth. In regard to scepticism in medicine, unfortunately it was the doctors who have set the bad example. The remark has often been made, "Never have philosophers, literary men, or poets, said so much against medical science as the doctors themselves." "Where could we find," continues the author, "for example, a judgment on therapeutics more cruel than this one? 'Incoherent assemblage of opinions, in themselves incoherent, it is, perhaps, of all physiological sciences that in which the oddities of the human mind are best depicted. I say that this is not a science suited to a methodical mind; it is an informal assemblage of inexact ideas, of observations which are often childish, of illusory means, of formulæ as curiously conceived as they are fastidiously arranged. It is said that the practice of medicine is repulsive; I go further, and say that, under certain conditions, it is not the practice of a reasonable man as its principles are carried out in the greater part of our materia medica.' Who expresses himself thus, gentlemen? No ordinary man; it is Bichat, whom we all more or less acknowledge, and rightly, to be one of the promoters of modern science. And it is by hundreds that we could borrow from our principal leaders in science portraits no less flattering, without reckoning Broussais, who says boldly that up to his time medicine has only lauded men in a chimerical hope, and, taken for all in all, has been more harmful than useful to mankind. After that we cannot wonder if men outside our ranks judge us with some severity. But was not the first word written of medicine one of discouragement and of doubt? *Ars longa, vita brevis, experientia fallax, judicium difficile.* This is the first of all the aphorisms of Hippocrates, and M. Peisse asks ironically how, after having written it, Hippocrates could have the courage to write the second and the following ones. Certainly this grand utterance is an admirable lesson of modesty and prudence. But it has not been always understood in this sense; and the fact is that between scepticism and medicine there has always existed a certain natural affinity.

"What were the causes of medical scepticism? Scepticism flattered two of the deepest and not most honorable of the instincts of our nature, idleness and vanity; idleness, by dispensing with the need of seeking for truth, which always requires an effort to be discovered, and which, like the kingdom of God, suffered violence; vanity, by setting us up to criticise, to reckon the labors of others at a cheap rate, and to take to ourselves the gentle persuasion that we see through the common prejudices. There was something of that at the bottom of all scepticism. There was also, for a great number of the most conscientious and reflective minds, the inevitable discouragement caused by the clashing of contradictory opinions, the difficulty of arriving at one's own conviction, the uncertainty of therapeutic results. Was it not in medicine above all, that phenomena, the most complicated and most difficult to study, present themselves under quite different aspects, though they are the same in reality? Was it not most difficult in medicine to lay down fixed and invariable rules which were not encumbered by numerous exceptions.

"It was particularly when we had lived much in the past, when we had stirred up the dust of the libraries, and looking on that mountain of books and manuscripts, the accumulation of centuries, that we thought of the smallness of the result, of the little already known, of all there was yet to learn; it was then, above all, that we experienced that satiety, even disgust of books; and we understand Sydenham's conceit when, in reply to one of his friends, who asked him which was the best book to read, he said, 'Read "Don Quixote."' But Sydenham was not a sceptic; the book which he well knew how to read was the book of Nature. But the real and most potent cause of scepticism was that whilst medicine was a science, it was also a profession. The profession drew largely upon science; this latter would always, whatever it might accomplish, come short of what was required of it. Men, for the most part, trouble themselves little about the progress of science; but when they are ill they want to be cured, and that is what they come to us for. Now there was in every medical man conscious of the dignity of his art, a painful feeling arising from his powerlessness in the presence of so many ills. What a contrast there was between the number of services that men expect of us, and that which we are really able to render. Science was incomplete; it always will be; never mind, we must prescribe. That was a pernicious habit for the scientific mind to acquire. In all ages, certainly formerly more than at the present time, dogmatism had been the father of medical scepticism. The narrowness and tyranny of dogma led directly to doubt, above all when it did not rest on very firm foundations. Now, when we wish to investigate the old spirit, what do we find? A vague and incomplete notion of the permanence of the laws of Nature. In the midst of hypotheses, sometimes mystic, sometimes grossly materialistic, on the *primum movens*, we are always met with this idea, more or less formulated, but everywhere admitted, that life is a capricious, indiscernible force; that in all its manifestations the exception is nearly as frequent as the rule; and that it is impossible, in these changing matters, to affirm anything positively."

"Gentlemen," continues the author, "do you believe that this manner of looking at things is so remote from us? Do you not often hear it said that the words 'never' and 'always' should not be used in medicine, where 'everything happens?' Have you never heard 'fickle medicines'—'uncertain diseases'—spoken of? Is it not scepticism that meets you in these vulgar forms—scepticism which is not, perhaps, acknowledged, but is none the less dangerous? It is often said nowadays that there are no systems, that the time for them is past; that now

men only believe in facts, etc. That is a point on which I take the liberty of being somewhat sceptical. Have we had none of them in France since the commencement of the century: physiological medicine, organic medicine, and, in face of the latter, the vitalist, numerical medicine, exact medicine, positive medicine, and even positivist medicine, which is not quite the same thing?

"I could mention others if I wished. Besides this, pretension to strictness and accuracy does not belong specially to our own time; it has always been so. Do you believe our fathers imagined that they made science fanciful? They also proclaimed the sovereignty of experience and the omnipotence of facts. Meanwhile, I willingly admit that systems have now lost much of their importance—until they recover it; I admit that, for the moment, warned by the example of the past, we do not embrace all science in a single formula; that at least our conceptions being more modest, have, for that reason, a better chance of being true. You see I give to the present time all the credit that propriety demands. I only ask of it to be thoroughly willing to recognize the defects in its qualifications, and it is in these defects that I find some of the causes of modern medical scepticism. I shall allude, first of all, to ignorance. It would be more consistent with good feeling, and more correct, even to say the abuse of science. To-day science is so vast that we are obliged to fortify ourselves under penalty of remaining unproductive. From this arises—notably in our time—that some of the most eminent men in their specialty are absolutely ignorant of anything not pertaining to it.

"And as it is always easier to doubt than to study, there are adepts, ready made, for certain kinds of partial scepticisms, such as therapeutic scepticism, so much in vogue among men of the world. There are other ways of abusing science which also end in doubt. The dominant character of actual science is, as I said just now, the direct intervention of physiology in the things of pathology. At the same time, physiology is not medicine. Their field of study is not even quite identical. There are, it is true, the same tissues and organs; but they react differently according to whether the man is well or ill; and it belongs to illness alone to provoke certain kinds of reactions which, up to the present at least, we have not been able to produce by experiments. "Who would suspect, in looking at the brain,' Hippocrates said 'that wine disturbs its functions?' Would the most exact knowledge of the functions of the skin teach us anything of the nature of small-pox? However small the ties may be which unite physiology to medicine, the quantity of light that the one throws upon the other is still quite inadequate. And we must not be surprised if some of the greatest physiologists still regard medicine with absolute scepticism. Such, with us, was Magendie, to whom we should be very forgiving because he has given us Claude Bernard. Formerly, for example, the efficacy of bleeding in cases of cerebral hemorrhage was believed in: a theory was founded on it of the *rapture sanguin*, and of the derivation of bloodletting. But the discovery of miliary aneurisms brings this theory to the ground; and at the same time the lancet loses favor.

"However, gentlemen, we affirm boldly, that it is only superficial minds who are led by the conquests of pathological anatomy to discredit the ancients, and to the presumptuous conclusion that there is nothing to do in therapeutics. It is too easy to answer them. Is it not due to the progress of pathological anatomy that we have to-day proof of the curability of phthisis, and of the possible evolution toward cicatrization of the tuberculous follicle? Is it not something, too, to know when we are on the wrong road? We change it, at least, and that is a great benefit to the patient. But you would blame me if I spent more time on such an easy refutation.

"Thus far I have defined and described the malady of scepticism, and we have together sought out its principal causes. Is there a remedy for this evil? But I hear an objection: Is scepticism really an evil? Is it an enemy to be combated? Is it not rather one of the peculiarities of human nature with which, in our inability to triumph over it, we had better make terms? In such a question, gentlemen, we must have sincerity. Formerly I had an old master, rather sceptical himself, who was groaning in my presence one day about the impotence of our art, and he added, 'It would not do to say that to young men, for it would discourage them; they will become aware of it soon enough.' For myself, I never could understand this way of looking at things; the truth should be declared to all, young or old. If the result of so much human labor and watchings and sacrifices were nothing, it would still be our duty to say so. Wilful error, when kept to one's self, may screen itself under the name of illusion, but when it is taught to others it can but be called by one name—a lie.

"But, gentlemen, who will dare to say that we are in that condition? If I were to hazard here a like enormity, what protests I should call forth! Is not your presence here a striking and emphatic negation of a system which, in pathology, leads to ignorance, in therapeutics to inaction? Let us endeavor to find out means to resist this fatal tendency, and to strengthen one another in our beliefs. The remedy for scepticism, gentlemen, is, above all, to be found in science itself, in science each day better worked out, better understood, the incessant progress of which acts as the desired corrective to its mistakes, and brings to its *postulata* the looked-for response. Each advance in theory brings about, sooner or later, a change in practice, which often comes whence it was least expected. It is not enough to proclaim the merits of exact science; in every science there is something of certainty and uncertainty. It is not enough either to run down the systematic mind. Have not the most famous systematists been often the most forward to decry the systems of others? It is not enough even to build upon the reputed solid foundations of pathological anatomy. Long before our illustrious Bouillaud had chosen as his motto Bichat's phrase: 'What is observation if we do not know where the evil is?' Celsus had said: 'How shall we treat a diseased organ of which we literally know nothing?' What we want, above all, is to put into daily practice the truth which underlies the following axioms: 1st, the absolute constancy of the laws which regulate life; 2d, the strict subordination of phenomena to certain conditions which have to be determined.

"Claude Bernard has called this last law 'determinism'—rather a barbarous expression, perhaps, and all the more open to dispute, inasmuch as its author even did not always use it in the same sense. But if the word is open to dispute, the thing is not; it is not a system, it is the very essence of the scientific spirit. I need not show you the uses to which Claude Bernard has applied it in physiology, and it would take too long to detail to you those to which

it can be turned in pathology. Allow me to give you one or two examples. I will be very brief. Let us take locomotor ataxy. For many years this disease was confounded with the vague groups of paraplegias; nothing was known of it, either its nature or its cause: it was treated at a venture; some patients were healed who certainly were not ataxics. That is the first stage of the disease: it is the period of ignorance. Then comes a second stage—that of anatomo-pathology: the injury is discovered, and known to be incurable. That is the period of discouragement. Finally, the third stage. It is stated that a large portion of these cases of ataxy (I do not say all) are dependent on syphilis; if these cannot be radically cured, at least the disease may be arrested in its development. Virulent and infectious diseases furnish us with a still more striking example. When, in these latter days, the study of spontaneous generation led to the discovery of that world of infinitesimal organisms which seem to beset us everywhere, one may well ask how the human species, how animal life itself, can resist these myriads of invisible enemies ever ready to take advantage of the least failure of the organism to penetrate in its room? Laying hold of this idea, a great surgeon, and also a thinker—Lister—has introduced a new method, which diminishes and suppresses the chances of consecutive infection in the great operations, extends the limits of his art, and assures the almost infallible success of daring attempts from which surgeons recoiled but a short time ago. On the other side, a man of genius, whose name I am proud to mention, my illustrious friend Pasteur, resuming and reducing to system your great Jenner's work, succeeded, by the methodical attenuation of the virus, in inaugurating the prophylaxy of virulent diseases, and thus opened up to us new and indefinite horizons. In view of such results, gentlemen, what ground has scepticism to rest on? We might, indeed, have to guard ourselves from excessive enthusiasm if our admiration were not fully justified by the discoveries already made.

"This, gentlemen, is the most telling way in which to reply to sceptics. The movement is not to be baffled. it proves itself. Let us not forget in the meantime an axiom of ancient medicine, which has survived all the dogmatic revolutions, and which Hippocrates defined as the *vis medicatrix naturæ*. It has often been laughed at. For my own part, I believe in it as firmly as in the most incontestable experimental facts. The interpretations, indeed, that have been given of it are questionable; but if so many, and sometimes such poor attempts have been able to explain it, it is precisely because the fact obtrudes itself on the attention. Recently, again, at the Academy of Medicine, in Paris, I noticed, in a statement of Pasteur's, that our eminent compatriot, trying to regulate the progressive attenuation of his virus, took for criterion the resistance which the organism of the sheep opposed to it. One virus kills one sheep in fifty; another, one in a hundred; a third, fifty in a hundred, etc. What does that mean, gentlemen? This condition which M. Pasteur brought about—thoughtful observer that he is—this 'receptivity,'—what is it at bottom, if not that force of resistance which exists in every living being, differing according to the species, and also according to the individual?

"Is it not in the main the same thing as the *vis medicatrix naturæ?* Whatever we may say to it, it is one of the dominant facts of medical science. This force of vital resistance, this more or less receptivity of the disease, will be always the indispensable auxiliary of the doctor; and, for my own part, I would give up the exercise of my art if I were not sustained by this ally. The incomparable difficulty of our art is the necessity of apportioning a just share to this element in the cure of diseases, and of conciliating it, in the interpretation of morbid phenomena, with the two fundamental axioms that I have already admitted. The task is arduous; but difficult as it may appear, gentlemen, be assured that harmony will be established. Be that as it may, taking into account this great force of vital resistance, made clear by the light of etiology, pathological anatomy is no longer a meditation upon death, but the science of indications; a profound saying which has been bequeathed to us by ancient medical science, and which always corresponds to the highest realities of art.

"When certainty is obtained on these three points, gentlemen, science will be nearly perfected; even whilst it is not, we are not quite disarmed, for we have the right to appeal to empiricism and to tradition; who of us would be able to do without that? It gives us, for want of something better, a kind of certainty which is not without value, and which does not hinder us from seeking a superior certainty. The patrimony that each medical generation bequeaths to that which comes after is twofold, the one of an absolute, the other of a relative value, but neither to be disdained. It is thus that we have received from our ancestors opium, quinquina, nearly all our best medicines, which have done us good service, and will do us still more, before we definitely fix their mode of action; in like manner we in our turn leave to our descendants chloroform, chloral, phenic acid, the salicylates, pilocarpine, and many other substances, which it belongs to the future to appreciate and to explain their various uses. Thus are formed what Cabanis has called so appropriately, "the practical certainties" of medical science; thus we come to the kind of certainty peculiar to the clinician, which resembles, in many respects, moral certainty, and which, without attaining to scientific certainty, has no less its place and rank beside her. The limits assigned to me do not allow of my adding more to this already lengthy address. As a fitting close, allow me, gentlemen, to quote a passage, which is like a *résumé* and conclusion of my subject, from Claude Bernard. I could not do better than leave with you the impression of these simple and forcible words. 'The sceptic,' says our great physiologist in his 'Introduction à la Médecine Expérimentale,' 'is he who believes not in science, but in himself; he believes enough in himself to dare to disown science, and to affirm that it is not subject to fixed and determined laws. The doubter is the real *savant;* he only doubts himself and his own interpretations, but he believes in science; he admits, even in the experimental sciences, a criterion or an absolute scientific principle.'"

---

THIRD DAY—FRIDAY, AUGUST 5TH.

ADDRESS ON MEDICAL LITERATURE BY JOHN S. BILLINGS, M.D., U.S.A.

After some introductory remarks, the speaker said: "It is usual to estimate that about one-thirtieth part of the whole mass of the world's literature belongs to medicine and its allied sciences. This corresponds very well to the results obtained from an examination of bibliographies and catalogues of the principal medical libraries. It appears from this

that our medical literature now forms a little over one hundred and twenty thousand volumes properly so-called, and about twice that number of pamphlets, and that this accumulation is now increasing at the rate of about one thousand five hundred volumes and two thousand five hundred pamphlets yearly.

"Let us consider the character of this

ANNUAL GROWTH

somewhat in detail, first giving some figures as the number of those who are producing it.

"There are at the present time, scattered over the earth, about one hundred and eighty thousand medical men, who, by a liberal construction of the phrase, may be said to be educated—that is, who have some kind of a diploma, and for whose edification this current medical literature is produced. Of this number about eleven thousand six hundred are producers of or contributors to this literature, being divided as follows: United States, 2,800; France and her colonies, 2,600; the German Empire and Austro-Hungary, 2,300; Great Britain and her colonies, 2,000; Italy, 600; Spain, 300; all others, 1,000. These figures should be considered in connection with the number of physicians in each country; but this I can only give approximately, as follows: United States, 65,000; Great Britain and her colonies, 35,000; Germany and Austro-Hungary, 32,000; France and her colonies, 26,000; Italy, 10,000; Spain, 5,000; all others, 17,000.

"It will be seen from these figures that the number of physicians who are writers is proportionately greatest in France and least in the United States. As regards France, this is largely due to the requirement of a printed thesis for graduation, which of itself adds between six and seven hundred annually to the number of writers.

"Excluding popular medicine, pathies, pharmacy, and dentistry, all of which were included in the figures for the annual product just given, we find that the contributions to medicine, properly so-called, form a little over one thousand volumes and one thousand six hundred pamphlets yearly.

"For 1879, Rupprecht's 'Bibliotheca' gives as the total number of new medical books, excluding pamphlets, periodicals, and transactions, 419, divided as follows, viz.: France, 187; Germany, 110; England, 43; Italy, 32; United States, 21; all others, 26. These figures are, however, too small, and especially so as regards Great Britain and the United States. The 'Index Medicus' for the same year shows by analysis that the total number of medical books and pamphlets, excluding periodicals and transactions, was 1,643, divided as follows: France, 541; Germany, 364; United States, 310; Great Britain, 182; all others, 246. This does not include the inaugural theses, of which 693 were published in France alone.

THE SPECIAL CHARACTERISTICS

of the literature of the present day are largely due to journals and transactions, and this is particularly true in medicine. Our periodicals contain the most recent observations, the most original matter, and are the truest representations of the living thought of the day, and of the tastes and wants of the great mass of the medical profession, a large part of whom, in fact, read very little else. They form about one-half of the current medical literature, and in the year 1879 amounted to 650 volumes, of which the United States produced 156; Germany, 129; France, 122; Great Britain, 154; Italy, 65; and Spain, 24. This is exclusive of journals of pharmacy, dentistry, etc., and of journals devoted to medical sects and isms.

"The total numbers of volumes of medical journals and transactions of all kinds was, for the year 1879, 850, and for 1880, 864. The figures for 1880 are too small, but the real increase is slight. During the year 1879, the total number of original articles in medical journals and transactions which were thought worth noting for the 'Index Medicus' was a little over 20,000. Of these there appeared in American periodicals, 4,781; in French, 4,608; in German, 4,027; in English, 3,592; in Italian, 1,210; in Spanish, 703; in all others, 1,248. The figures for 1880 are about the same. It will be seen that at present more of this class of literature appears in the English language than in any other, and that the number of journal contributions is greatest in the United States. The actual bulk of periodical literature is, however, largest in Germany, owing to the greater average length of the articles. With regard to the mode of publication, I will only say that in all countries, except Spain, the greater number of medical periodicals are monthly, while in Spain they are semi-monthly. It is this periodical literature which, more than anything else, makes medicine cosmopolitan, and although as regards new discoveries or methods of treatment it is still somewhat farther from London or Berlin or Paris to New York than it is from New York to either of these places, the discrepancy is gradually becoming less.

"Many of the medical journals are very short-lived, but the total number is increasing. In 1879, twenty-three such journals ceased, but sixty new ones appeared, and in 1880 there were twenty-four deaths and seventy-eight births in this department of literature Over one-third of this fluctuation occurs in the United States alone, France being next in the scale, Spain third, and Italy fourth, while Great Britain is the most stable of all.

"This merely quantitative classification gives of course no idea as to the

CHARACTER OF THE PRODUCT.

"Let us now consider it by subjects. During 1879 there were published 167 books and pamphlets and 1,543 articles relating to anatomy, physiology, and pathology—that is, to the biological or scientific side of medicine. Dividing this again by nations, we find that Germany produced a majority of the whole, France being second. The proportionate production by nations of this class of literature is perhaps better shown by an analysis of the bibliography of physiological literature for the year 1879, as published by the *Journal of Physiology*. This shows 59 treatises and 500 articles in German; 17 treatises and 227 articles in French; 5 treatises and 77 articles from Great Britain; 8 treatises and 41 articles from Italy; and 2 treatises and 24 articles from the United States. The number of authors for this product was: German, 373; French, 119; English, 59; Italian, 39; United States, 19; all others, 41. For the year 1880 the same journal reports 62 treatises and 452 articles from Germany; 23 treatises and 216 articles from France; 12 treatises and 76 articles from Great Britain; 4 treatises and 51 articles from Italy; 6 treatises and 25 articles from the United States; and 10 treatises and 31 articles from all other countries.

"When we return to the literature of the art, or practical side of the profession, the figures are decidedly different. We find over 1,200 treatises and

18,000 journal articles which come under this head, and the order of precedence of countries as to quantity is: France, United States, Germany, Great Britain, Italy, and Spain. A marked increase has occurred in the literature of hygiene during the last two years, and this especially in England, France, Germany, and the United States. The literature of diseases of the nervous system, of ophthalmology, otology, dermatology and gynæcology is also increasing more rapidly than that of the more general branches."

The speaker then referred to the increased attention paid to the more scientific study of medicine everywhere.

While admitting the priority of Germany as regards scientific medicine, he said: "Such priority, however, is not the case with regard to therapeutics, either external or internal—in regard to which I presume that the physicians of each nation are satisfied as to their own pre-eminence. At all events it is true, that for the treatment of the common diseases a physician can obtain his most valuable instruction in his own country, among those whom he is to treat. Just as each individual is in some respects peculiar and unique, so that even the arrangement of the minute ridges and furrows at the end of his forefinger differs from that of all other forefingers, and is sufficient to identify him; and as the members of certain families require special care to guard against hemorrhage, or insanity, or phthisis, so it is with nations and races. The experienced military surgeon knows this well, and in the United States, which is now the great mixing ground, illustrations of race peculiarities are familiar to every practitioner."

Speaking of the alleged tendency of present scientific work toward utilitarianism, he said that "this tendency was by no means universal, for science was becoming fashionable. And we see such individuals as the languid scientific swell, who thinks it bad style to be practical, who takes no interest in anything but pure science, and makes it a point to refrain from any investigations which might lead to useful results lest he might be confounded with mere inventors, exists and has his admirers. We have such in medicine, and their number will increase."

The speaker then referred to the increased fondness for book-collecting and library-making. He also discussed the future of medical literature and medical libraries. He thought that the present rate of increase would not continue. It had, indeed, already become smaller in some places, especially in Western Europe.

To those who might be discouraged at the immense bibliography of every medical subject, he would say that there were few books of any value older than the present century. Those were the works of Hippocrates, Galen, Harvey, Hunter, Morgagni, and Sydenham.

Speaking of the Index Catalogue of the library of the Surgeon-General's office, he stated that at least one-half of the references were of no value so long as the other half is accessible.

An important suggestion was made in regard to instruction in the history and literature of medicine in medical colleges. Such instruction forms no part of the course in English or American schools, nor would the writer be disposed to recommend its introduction into the curriculum if it were to be based on French and German models; but it does seem possible to take a step in this direction which would be of great value, not only as a means of general culture, as teaching students how to think, but from a purely practical point of view, in teaching them how to use the implements of their profession to the best advantage—for books are properly compared to tools, of which the index is the handle. Such instruction should be given in a library, just as chemistry should be taught in a laboratory.

The speaker made an appeal in behalf of the bibliographer, which deserves attention.

"The editors of Transactions of Societies, whether these are sent to journals, or published in separate form, often commit numerous sins of omission in the matter of titles. The rule should be that every article which is worth printing is worth a distinct title, which should be as concise as a telegram, and be printed in a special type. If the author does not furnish such a title it is the editor's business to make it; and he should not be satisfied with such headings as 'Clinical Cases,' 'Difficult Labor,' 'A Remarkable Tumor,' 'Case of Wound, with Remarks.' The four rules for the preparation of an article for a journal will then be: 1st, have something to say; 2d, say it; 3d, stop as soon as you have said it; 4th, give the paper a proper title."

---

### Fifth Day—Monday, August 8th.

#### Address on the Germ Theory by Professor Pasteur.

After a few introductory remarks, acknowledging the honor of the invitation to address the Congress, the distinguished professor said: "I should be guilty of ingratitude and of false modesty if I did not accept the welcome I have received among you and in English society as a mark of homage paid to my labors during the past five-and-twenty years upon the nature of ferments—their life and their nutrition, their preparation in a pure state by the introduction of organisms (*ensemencement*) under natural and artificial conditions—labors which have established the principles and the methods of microbie (microbism), if the expression is allowable. Your cordial welcome has revived within me the lively feeling of satisfaction I experienced when your great surgeon Lister declared that my publication in 1857 on milk fermentation had inspired him with his first ideas on his valuable surgical method. You have reawakened the pleasure I felt when our eminent physician, Dr. Davaine, declared that his labors upon charbon (splenic fever or malignant pustule) had been suggested by my studies on butyric fermentation and the vibrion which is characteristic of it. Gentlemen, I am happy to be able to thank you by bringing to your notice a new advance in the study of microbie as applied to the prevention of transmissible diseases—diseases which for the most part are fraught with terrible consequences, both for man and domestic animals.

"The subject of my communication is vaccination in relation to chicken cholera and splenic fever, and a statement of the method by which we have arrived at these results—a method the fruitfulness of which inspires me with boundless anticipations. Before discussing the question of splenic fever vaccine, which is the most important, permit me to recall the results of my investigations of chicken cholera. It is through this inquiry that new and highly important principles have been introduced into science concerning the virus or contagious quality of transmissible diseases. More than once in what I am about to say I shall employ the expression virus-cul-

ture, as formerly, in my investigations on fermentation, I used the expressions, the culture of milk ferment, the culture of the butyric vibrion, etc. Let us take, then, a fowl which is about to die of chicken cholera, and let us dip the end of a delicate glass rod in the blood of the fowl with the usual precautions, upon which I need not here dwell. Let us then touch with this charged point some *bouillon de poule*, very clear, but first of all rendered sterile under a temperature of about 115° centigrade, and under conditions in which neither the outer air nor the vases employed can introduce exterior germs—those germs which are in the air, or on the surface of all objects. In a short time, if the little culture vase is placed in a temperature of 25° to 35°, you will see the liquid become turbid and full of tiny microbes, shaped like the figure 8, but often so small that under a high magnifying power they appear like points. Take from this vase a drop as small as you please, no more than can be carried on the point of a glass rod as sharp as a needle, and touch with this point a fresh quantity of sterilized *bouillon de poule* placed in a second vase, and the same phenomenon is produced. You deal in the same way with a third culture vase, with a fourth, and so on to a hundred, or even a thousand, and invariably within a few hours the culture liquid becomes turbid and filled with the same minute organisms.

"At the end of two or three days' exposure to a temperature of about 30° C. the thickness of the liquid disappears, and a sediment is formed at the bottom of the vase. This signifies that the development of the minute organism has ceased—in other words, all the little points which caused the turbid appearance of the liquid have fallen to the bottom of the vase, and things will remain in this condition for a longer or shorter time, for months even, without even the liquid or the deposit undergoing any visible modification, inasmuch as we have taken care to exclude the germs of the atmosphere. A little stopper of cotton sifts the air which enters or issues from the vase through changes of temperature. Let us take one of our series of culture preparations—the hundredth or the thousandth, for instance—and compare it in respect to its virulence with the blood of a fowl which has died of cholera; in other words, let us inoculate under the skin ten fowls, for instance, each separately with a tiny drop of infectious blood, and ten others with a similar quantity of the liquid in which the deposit has first been shaken up. Strange to say, the latter ten fowls will die as quickly and with the same symptoms as the former ten; the blood of all will be found to contain after death the same minute infectious organisms. This equality, so to speak, in the virulence both of the culture preparation and of the blood is due to an apparently futile circumstance. I have made a hundred culture preparations—at least, I have understood that this was done—without leaving any considerable interval between the impregnations. Well, here we have the cause of the equality in the virulence.

"Let us now repeat exactly our successive cultures with this single difference, that we pass from one culture, to that which follows it—from the hundredth to, say, the hundred and first, at intervals of a fortnight, a month, two months, three months, or ten months. If, now, we compare the virulence of the successive cultures, a great change will be observed. It will be readily seen from an inoculation of a series of ten fowls that the virulence of one culture differs from that of the blood and from that of a preceding culture when a sufficiently long interval elapses between the impregnation of one culture with the microbe of the preceding. More than that, we may recognize by this mode of observation that it is possible to prepare cultures of varying degrees of virulence. One preparation will kill eight fowls out of ten, another five out of ten, another one out of ten, another none at all, although the microbe may still be cultivated. In fact, what is no less strange, if you take each of these cultures of attenuated virulence as a point of departure in the preparation of successive cultures and without appreciable interval in the impregnation, the whole series of these cultures will reproduce the attenuated virulence of that which has served as the starting point. Similarly, where the virulence is null it produces no effect. How, then, it may be asked, are the effects of these attenuating virulences revealed in the fowls? They are revealed by a local disorder, by a morbid modification more or less profound in a muscle, if it is a muscle which has been inoculated with the virus. The muscle is filled with microbes which are easily recognized, because the attenuated microbes have almost the bulk, the form, and the appearance of the most virulent microbes.

"But why is not the local disorder followed by death? For the moment let us answer by a statement of facts. They are these: the local disorder ceases of itself more or less speedily, the microbe is absorbed and digested, if one may say so, and little by little the muscle regains its normal condition. Then the disease has disappeared. When we inoculate with the microbe, the virulence of which is null, there is not even local disorder, the *nature medicatrix* carries it off at once, and here, indeed, we see the influence of the resistance of life, since this microbe, the virulence of which is null, multiplies itself. A little farther, and we touch the principle of vaccination. When the fowls have been rendered sufficiently ill by the attenuated virus which the vital resistance has arrested in its development, they will, when inoculated with virulent virus, suffer no evil effects, or only effects of a passing character. In fact, they no longer die from the mortal virus, and for a time sufficiently long, which in some cases may exceed a year, chicken cholera cannot touch them, especially under the ordinary conditions of contagion which exist in fowl-houses. At this critical point of our manipulation—that is to say, in this interval of time which we have placed between two cultures, and which causes the attenuation—what occurs? I shall show you that in this interval the agent which intervenes is the oxygen of the air. Nothing more easily admits of proof. Let us produce a culture in a tube containing very little air, and close this tube with an enameller's lamp. The microbe in developing itself, will speedily take all the oxygen of the tube and of the liquid, after which it will be quite free from contact with oxygen. In this case it does not appear that the microbe becomes appreciably attenuated, even after a great lapse of time. The oxygen of the air, then, would seem to be a possible modifying agent of the virulence of the microbe of chicken cholera—that is to say, it may modify more or less the facility of its development in the body of animals. May we not be here in presence of a general law applicable to all kinds of virus? What benefits may not be the result? We may hope to discover in this way the vaccine of all virulent diseases; and what is more natural than to begin our investigation of the vaccine of what we

in French call charbon, what you in England call splenic fever, and what in Russia is known as the Siberian pest, and in Germany as the Milzbrand.

"In this new investigation I have had the assistance of two devoted young *savants*—MM. Chamberland and Roux. At the outset we were met by a difficulty. Among the inferior organisms, all do not resolve themselves into those corpuscle germs which I was the first to point out as one of the forms of their possible development. Many infectious microbes do not resolve themselves in their cultures into corpuscle germs. Such is equally the case with beer yeast, which we do not see develop itself usually in breweries, for instance, except by a sort of scissiparity. One cell makes two or more, which form themselves in wreaths; the cells become detached, and the process recommences. In these cells real germs are not usually seen. The microbe of chicken-cholera and many others behave in this way, so much so that the cultures of this microbe, although they may last for months without losing their power of fresh cultivation, perish finally like beer yeast which has exhausted all its aliments. The anthracoid microbe in artificial cultures behaves very differently. In the blood of animals, as in cultures, it is found in translucid filaments more or less segmented. This blood or these cultures freely exposed to air, instead of continuing according to the first mode of generation, show at the end of forty-eight hours corpuscle germs distributed in series more or less regular along the filaments. All around these corpuscles matter is absorbed, as I have represented it formerly in one of the plates of my work on the diseases of silkworms. Little by little all connection between them disappears, and presently they are reduced to nothing more than germ dust.

"If you make these corpuscles germinate, the new culture reproduces the virulence peculiar to the thready form which has produced these corpuscles, and this result is seen even after a long exposure of these germs to contact with air. Recently we discovered them in pits in which animals dead of splenic fever had been buried for twelve years, and their culture was as virulent as that from the blood of an animal recently dead. Here I regret extremely to be obliged to shorten my remarks. I should have had much pleasure in demonstrating that the anthracoid germs in the earth of pits in which animals have been buried are brought to the surface by earthworms, and that in this fact we may find the whole etiology of disease, inasmuch as the animals swallow these germs with their food. A great difficulty presents itself when we attempt to apply our method of attenuation by the oxygen of the air to the anthracoid microbes. The virulence establishing itself very quickly, often after twenty-four hours in an anthracoid germ which escapes the action of the air, it was impossible to think of discovering the vaccine of splenic fever in the conditions which had yielded that of chicken cholera. But was there, after all, reason to be discouraged? Certainly not; in fact, if you observe closely, you will find that there is no real difference between the mode of the generation of the anthracoid germ by scission and that of chicken cholera. We had therefore reason to hope that we might overcome the difficulty which stopped us by endeavoring to prevent the anthracoid microbe from producing corpuscle germs, and to keep it in this condition in contact with oxygen for days, and weeks, and months. The experiment fortunately succeeded.

"In the ineffective *(neutre) bouillon de poule* the anthracoid microbe is no longer cultivable at 45° C. Its culture, however, is easy at 42° or 43°, but in these conditions the microbe yields no spores. Consequently it is possible to maintain in contact with the pure air at 42° or 43° a *mycélienne* culture of bacteria entirely free of germs. Then appear the very remarkable results which follow. In a month or six weeks the culture dies — that is to say, if one impregnates with it fresh *bouillon*, the latter is completely sterile. Up till that time life exists in the vase exposed to air and heat. If we examine the virulence of the culture at the end of two days, four days, six days, eight days, etc., it will be found that long before the death of the culture the microbe has lost all virulence, although still cultivable. Before this period it is found that the culture presents a series of attenuated virulences. Everything is similar to what happens in respect to the microbe in chicken cholera. Besides, each of these conditions of attenuated virulence may be reproduced by culture; in fact, since the charbon does not operate a second time *(ne récidive pas)*, each of our attenuated anthracoid microbes constitutes for the superior microbe a vaccine — that is to say, a virus capable of producing a milder disease. · Here, then, we have a method of preparing the vaccine of splenic fever. You will see presently the practical importance of this result, but what interests us more particularly is to observe that we have here a proof that we are in possession of a general method of preparing virus vaccine based upon the action of the oxygen and the air — that is to say, of a cosmic force existing everywhere on the surface of the globe.

"I regret to be unable, from want of time, to show you that all these attenuated forms of virus may very easily, by a physiological artifice, be made to recover their original maximum virulence. The method I have just explained of obtaining the vaccine of splenic fever was no sooner made known than it was very extensively employed to prevent the splenic affection. In France we lose every year, by splenic fever, animals of the value of twenty million francs. I was asked to give a public demonstration of the results already mentioned. This experiment I may relate in a few words. Fifty sheep were placed at my disposition, of which twenty-five were vaccinated. A fortnight afterward the fifty sheep were inoculated with the most virulent anthracoid microbe. The twenty-five vaccinated sheep resisted the infection; the twenty-five unvaccinated died of splenic fever within fifty hours. Since that time my energies have been taxed to meet the demands of farmers for supplies of this vaccine. In the space of fifteen days we have vaccinated in the departments surrounding Paris more than twenty thousand sheep, and a large number of cattle and horses. If I were not pressed for time I would bring to your notice two other kinds of virus attenuated by similar means. These experiments will be communicated by and by to the public. I cannot conclude, gentlemen, without expressing the great pleasure I feel at the thought that it is as a member of an international medical congress assembled in England that I make known the most recent results of vaccination upon a disease more terrible, perhaps, for domestic animals than small-pox is for man. I have given to vaccination an extension which science, I hope, will accept as a homage paid to the merit and to the immense services rendered by one of the greatest men of England, Jenner. What a pleasure for me to do honor to this immortal name in this noble and hospitable city of London!"

Sir James Paget remarked, that in thanking Professor Pasteur, as he did in the name of the Congress, for the address they had just heard, he was only expressing the sense of the whole world. Professor Pasteur had done for the lower animals what Jenner had already done for the human race, and it was not a little remarkable that while Jenner, in seeking to benefit mankind, had to fight against a vehement opposition, Professor Pasteur's investigations for the benefit of mere human property met with no opposition. (Cheers and laughter.) Probably as the result of these researches, human vaccination would be viewed with more favor in some quarters than it had hitherto been.

Professor Volkmann read a paper in German at the same meeting, on "Modern Surgery," in which he paid a tribute to Professor Lister as the discoverer of the antiseptic system, whereby the treatment of fractures and amputation of the limbs had been rendered very much safer than was previously the case.

---

### Sixth Day—Tuesday, August 9th.

#### The connection of the biological sciences with medicine.—address by T. H. Huxley, ll.d.

After a general introduction to his subject, the learned orator remarked:

"The great man whose name is inseparably connected with the foundation of medicine, Hippocrates, certainly knew very little—indeed, practically nothing—of anatomy or physiology; and he would probably have been perplexed even to imagine the possibility of a connection between the zoölogical studies of his contemporary, Democritus, and medicine. Nevertheless, in so far as he and those who worked before and after him in the same spirit ascertained, as matters of experience, that a wound or a luxation, or a fever, presented such and such symptoms, and that the return of the patient to health was facilitated by such and such measures, they established laws of Nature and began the construction of the science of pathology. All true science begins with empiricism, though all true science is such exactly in so far as it strives to pass out of the empirical stage into that of the deduction of empirical from more general truths. Thus, it is not wonderful that the early physicians had little or nothing to do with the development of biological science; and, on the other hand, that the early biologists did not much concern themselves with medicine. There is nothing to show that the Asclepiads took any prominent share in the work of founding anatomy, physiology, zoology, and botany. Rather do these seem to have sprung from the early philosophers, who were essentially natural philosophers, animated by the characteristically Greek thirst for knowledge as such. Pythagoras, Alcmeon, Democritus, Diogenes of Apollonia, are all credited with anatomical and physiological investigation; and though Aristotle is said to have belonged to an Asclepiad family, and not improbably owed his taste for anatomical and zoölogical inquiries to the teachings of his father, the physician Nicomachus, the 'Historia Animalium,' and the treatise 'De Partibus Animalium,' are as free from any allusion to medicine as if they had issued from a modern biological laboratory.

"It may be added, that it is not easy to see in what way it could have benefited a physician of Alexander's time to know all that Aristotle knew on these subjects. His human anatomy was too rough to avail much in diagnosis, his physiology was too erroneous to supply data for pathological reasoning. But when the Alexandrian school, with Erasistratus and Herophilus at their head, turned to account the opportunities of studying human structure afforded to them by the Ptolemies, the value of the large amount of accurate knowledge thus obtained to the surgeon for his operations, and to the physician for his diagnosis of internal disorders, became obvious, and a connection was established between anatomy and medicine, which has ever become closer and closer. Since the revival of learning, surgery, medical diagnosis, and anatomy have gone hand in hand. Morgagni called his great work 'De Sedibus et Causis Morborum per Anatomen Indagatis,' and not only showed the way to search out the localities and the causes of disease by anatomy, but himself travelled wonderfully far upon the road. Bichat, discriminating the grosser constituents of the organs and parts of the body one from another, pointed out the direction which modern research must take; until at length histology, a science of yesterday, as it seems to many of us, has carried the work of Morgagni as far as the microscope can take us, and has extended the realm of pathological anatomy to the limits of the invisible world.

"Thanks to the intimate alliance of morphology with medicine, the natural history of disease has, at the present day, attained a high degree of perfection. Accurate regional anatomy has rendered practicable the exploration of the most hidden parts of the organism, and the determination during life of morbid changes in them; anatomical and histological post-mortem investigations have supplied physicians with a clear basis upon which to rest the classification of diseases, and with unerring tests of the accuracy or inaccuracy of their diagnosis. If men could be satisfied with pure knowledge, the extreme precision with which, in these days, a sufferer may be told what is happening, and what is likely to happen, even in the most recondite parts of his bodily frame, should be as satisfactory to the patient as it is to the scientific pathologist who gives him the information. But I am afraid it is not; and even the practising physician, while nowise under-estimating the regulative value of accurate diagnosis, must often lament that so much of his knowledge rather prevents him from doing wrong than helps him to do right. A scorner of physic once said that Nature and disease may be compared to two men fighting, the doctor to a blind man with a club, who strikes into the *mêlée*, sometimes hitting the disease and sometimes hitting Nature. The matter is not mended if you suppose the blind man's hearing to be so acute that he can register every stage of the struggle and pretty clearly predict how it will end. He had better not meddle at all until his eyes are opened—until he can see the exact position of the antagonists, and make sure of the effect of his blows. But that which it behoves the physician to see, not indeed with his bodily eye, but with clear intellectual vision, is a process, and the chain of causation involved in that process. Disease, as we have seen, is a perturbation of the normal activities of a living body; and it is and must remain unintelligible so long as we are ignorant of the nature of these normal activities. In other words, there could be no real science of pathology until the science of physiology had reached a degree of perfection unattained, and indeed unattainable, until quite recent times.

"So far as medicine is concerned, I am not sure

that physiology, such as it was down to the time of Harvey, might as well not have existed. Nay, it is, perhaps, no exaggeration to say that, within the memory of living men, justly renowned practitioners of medicine and surgery knew less physiology than is now to be learned from the most elementary text-book, and, beyond a few broad facts, regarded what they did know as of extremely little practical importance. Nor am I disposed to blame them for this conclusion; physiology must be useless, or worse than useless, to pathology, so long as its fundamental conceptions are erroneous. Harvey is often said to be the founder of modern physiology, and there can be no question that the elucidations of the function of the heart, of the nature of the pulse, and of the course of the blood, put forth in the ever-memorable little essay, 'De motu cordis,' directly worked a revolution in men's views of the nature and of the concatenation of some of the most important physiological processes among the higher animals, while indirectly their influence was perhaps even more remarkable. But, though Harvey made this signal and perennially important contribution to the physiology of the moderns, his general conception of vital processes was essentially identical with that of the ancients; and in the 'Exercitationes de generatione,' and notably in the singular chapter, 'De calido innato,' he shows himself a true son of Galen and of Aristotle. For Harvey, the blood possesses powers superior to those of the elements; it is the seat of a soul which is not only vegetative, but also sensitive and motor. The blood maintains and fashions all parts of the body, *idque summâ cum providentia et intellectu, in finem certum agens, quasi ratiocinio quodam uteretur.* Here is the doctrine of the *pneuma*, the product of the philosophical mould into which the animism of primitive men ran in Greece, in full force. Nor did its strength abate for long after Harvey's time. The same ingrained tendency of the human mind to suppose that a process is explained when it is ascribed to a power of which nothing is known except that it is the hypothetical agent of the process, gave rise, in the next century, to the animism of Stahl; and later to the doctrine of a vital principle, that *asylum ignorantiæ* of physiologists, which has so easily accounted for everything and explained nothing, down to our own times.

"Now, the essence of modern, as contrasted with ancient physiological science, appears to me to lie in its antagonism to animistic hypotheses and animistic phraseology. It offers physical explanations of vital phenomena, or frankly confesses that it has none to offer. And, so far as I know, the first person who gave expression to this modern view of physiology, who was bold enough to enunciate the proposition that vital phenomena, like all the other phenomena of the physical world, are in ultimate analysis, resolvable into matter and motion, was René Descartes. The fifty-four years of life of this most original and powerful thinker are widely overlapped on both sides by the eighty of Harvey, who survived his younger contemporary by seven years, and takes pleasure in acknowledging the French philosopher's appreciation of his great discovery. In fact, Descartes accepted the doctrine of the circulation as propounded by 'Hervæus, médecin d'Angleterre,' and gave a full account of it in his first work, the famous 'Discours de la Méthode,' which was published in 1637, only nine years after the exercitation 'De motu cordis;' and, though differing from Harvey in some important points (in which it may be noted in passing, Descartes was wrong and Harvey right), he always speaks of him with great respect. And so important does the subject seem to Descartes, that he returns to it in the 'Traité des Passions,' and in the 'Traité de l'Homme.'

"It is easy to see that Harvey's work must have had a peculiar significance for the subtle thinker, to whom we owe both the spiritualistic and the materialistic philosophies of modern times. It was in the very year of its publication, 1628, that Descartes withdrew into that life of solitary investigation and meditation of which his philosophy was the fruit; and, as the course of his speculations led him to establish an absolute distinction of Nature between the material and the mental worlds, he was logically compelled to seek for the explanation of the phenomena of the material world within itself, and having allotted the realm of thought to the soul, to see nothing but extension and motion in the rest of Nature. Descartes uses 'thought' as the equivalent of our modern term 'consciousness.' Thought is the function of the soul, and its only function. Our natural heat and all the movements of the body, says he, do not depend on the soul. Death does not take place from any fault of the soul, but only because some of the principal parts of the body become corrupted. The body of a living man differs from that of a dead man in the same way as a watch or other automaton (that is to say, a machine which moves of itself) when it is wound up, and has in itself the physical principle of the movements which the mechanism is adapted to perform, differs from the same watch or other machine when it is broken, and the physical principle of its movement no longer exists. All the actions which are common to us and the lower animals depend only on the conformation of our organs and the course which the animal spirits take in the brain, the nerves, and the muscles, in the same way as the movement of a watch is produced by nothing but the force of its spring and the figure of its wheels and other parts.

"Descartes' treatise on 'Man' is a sketch of human physiology in which a bold attempt is made to explain all the phenomena of life, except those of consciousness, by physical reasonings. To a mind turned in this direction Harvey's exposition of the heart and vessels as a hydraulic mechanism must have been supremely welcome. Descartes was not a mere philosophical theorist, but a hard-working dissector and experimenter, and he held the strongest opinion respecting the practical value of the new conception which he was introducing. He speaks of the importance of preserving health, and of the dependence of the mind on the body being so close that perhaps the only way of making men wiser and better than they are is to be sought in medical science. 'It is true,' says he, 'that as medicine is now practised it contains little that is very useful; but without any desire to depreciate, I am sure that there is no one, even among professional men, who will not declare that all we know is very little as compared with that which remains to be known; and that we might escape an infinity of diseases of the mind, no less than of the body, and even perhaps from the weakness of old age, if we had a sufficient knowledge of their causes and of all the remedies with which nature has provided us.'* So strongly impressed was Descartes with this that he resolved to spend the rest of his life in trying to acquire such

* Discours de la Méthode. 6me partie. Ed. Cousin. P. 193

a knowledge of nature as would lead to the construction of a better medical doctrine.* The anti-Cartesians found material for cheap ridicule in these aspirations of the philosopher; and it is almost needless to say that, in the thirteen years which elapsed between the publication of the 'Discours' and the death of Descartes, he did not contribute much to their realization. But for the next century all progress in physiology took place along the lines which Descartes laid down.

"The greatest physiological and pathological work of the seventeenth century, Borelle's treatise 'De motu animalium,' is, to all intents and purposes, a development of Descartes' fundamental conception; and the same may be said of the physiology and pathology of Boerhaave, whose authority dominated in the medical world in the first half of the eighteenth century. With the origin of modern chemistry and of electrical science, in the latter half of the eighteenth century, aids in the analysis of the phenomena of life, of which Descartes could not have dreamed, were offered to the physiologist. And the greater part of the gigantic progress which has been made in the present century is a justification of the provision of Descartes. For it consists essentially in a more and more complete resolution of the grosser organs of the living body into physico-chemical mechanisms. 'I shall try to explain our whole bodily machinery in such a way that it will be no more necessary for us to suppose that the soul produces such movements as are not voluntary than it is to think that there is in a clock a soul which causes it to show the hours.'† These words of Descartes might be appropriately taken as a motto by the author of any modern treatise on physiology.

"But though, as I think, there is no doubt that Descartes was the first to propound the fundamental conception of the living body as a physical mechanism, which is the distinctive feature of modern as contrasted with ancient physiology, he was misled by the natural temptation to carry out, in all its details, a parallel between the machines with which he was familiar, such as clocks and pieces of hydraulic apparatus, and the living machine. In all such machines there is a central source of power, and the parts of the machine are merely passive distributors of that power. The Cartesian school conceived of the living body as a machine of this kind; and herein they might have learned from Galen, who, whatever ill use he may have made of the doctrine of "natural faculties," nevertheless had the great merit of perceiving that local forces play a great part in physiology. The same truth was recognized by Glisson, but it was first prominently brought forward in the Hallerian doctrine of the 'vis insita' of muscles. If muscle can contract without nerve, there is an end of the Cartesian mechanical explanation of its contraction by the influx of animal spirits.

"The discoveries of Trembley tended in the same direction. In the fresh water *Hydra* no trace was to be found of that complicated machinery upon which the performance of the functions in the higher animals was supposed to depend. And yet the hydra moved, fed, grew, multiplied, and its fragments exhibited all the powers of the whole. And, finally, the work of Caspar F. Wolff,‡ by demonstrating the fact that the growth and development of both plants and animals take place antecedently to the existence of their grosser organs, and are, in fact, the causes and not the consequences of organization (as then understood), sapped the foundations of the Cartesian physiology as a complete expression of vital phenomena. For Wolff, the physical basis of life is a fluid, possessed of a 'vis essentialis' and a 'solidescibilitas;' in virtue of which it gives rise to organization; and, as he points out, this conclusion strikes at the root of the whole iatro-mechanical system.

"In this country the great authority of John Hunter exerted a similar influence, though it must be admitted that the too sibylline utterances which are the outcome of Hunter's struggles to define his conceptions are often susceptible of more than one interpretation. Nevertheless, on some points Hunter is clear enough. For example, he is of opinion that 'spirit is only a property of matter' ('Introduction to Natural History,' page 6), he is prepared to renounce animism (l. c., p. 8), and his conception of life is so completely physical that he thinks of it as something which can exist in a state of combination in the food. 'The aliment we take in has in it, in a fixed state, the real life, and this does not become active until it has got into the lungs, for there it is freed from its prison' ('Observations on Physiology,' p. 113). He also thinks that: 'It is more in accord with the general principles of the animal machine to suppose that none of its effects are produced from any mechanical principle whatever, and that every effect is produced from an action in the part, which action is produced by a stimulus upon the part which acts, or upon some other part with which this part sympathizes, so as to take up the whole action' (l. c., p. 152). And Hunter is as clear as Wolff, with whose work he probably was unacquainted, that 'whatever life is, it most certainly does not depend upon structure or organization' (l. c., p. 114).

"Of course, it is impossible that Hunter could have intended to deny the existence of purely mechanical operations in the animal body. But while, with Borelli and Boerhaave, he looked upon absorption, nutrition, and secretion as operations effected by means of the small vessels, he differed from the mechanical physiologists, who regarded these operations as the result of the mechanical properties of the small vessels, such as the size, form, and disposition of their canals and apertures. Hunter, on the contrary, considers them to be the effect of properties of these vessels which are not mechanical, but vital. 'The vessels,' says he, 'have more of the polypus in them than any other part of the body,' and he talks of the 'living and sensitive principles of the arteries,' and even of the 'dispositions or feelings of the arteries.' 'When the blood is good and genuine, the sensations of the arteries, or the dispositions for sensation, are agreeable. . . . It is then they dispose of the blood to the best advantage, increasing the growth of the whole, supplying any losses, keeping up a due succession, etc.' (l. c., p. 133).

"If we follow Hunter's conceptions to their logical issue, the life of one of the higher animals is essentially the sum of the lives of all the vessels, each of which is a sort of physiological unit, answering to a polyp; and, as health is the result of the normal "action of the vessels," so is disease an effect of their abnormal action. Hunter thus stands in thought, as in time, midway between Borelli, on the one hand, and Bichat, on the other. The acute founder of general anatomy, in fact, outdoes Hunter

* Discours de la Méthode. 6me partie. Ed. Cousin. Pp. 193 and 211.
† De la Formation du Fœtus.
‡ Theoria Generationis, 1759.

in his desire to exclude physical reasonings from the realm of life. Except in the interpretation of the action of the sense organs, he will not allow physics to have anything to do with physiology. 'To apply the physical sciences to physiology is to explain the phenomena of living bodies by the laws of inert bodies. Now, this is a false principle, hence all its consequences are marked with the same stamp. Let us leave to chemistry its affinity, to physics its elasticity and its gravity. Let us invoke for physiology only sensibility and contractility.' * Of all the unfortunate dicta of men of eminent ability this seems one of the most unhappy, when we think of what the application of the methods and the data of physics and chemistry has done toward bringing physiology into its present state. It is not too much to say that one-half of a modern text-book of physiology consists of applied physics and chemistry, and that it is exactly in the exploration of the phenomena of sensibility and contractility that physics and chemistry have exerted the most potent influence.

"Nevertheless, Bichat rendered a solid service to physiological progress by insisting upon the fact that what we call life in one of the higher animals is not an invisible unitary archæus dominating from its central seat the parts of the organism, but a compound result of the synthesis of the separate lives of those parts. 'All animals,' says he, 'are assemblages of different organs, each of which performs its function and concurs, after its fashion, in the preservation of the whole. They are so many special machines in the general machine which constitutes the individual. But each of these special machines is itself compounded of many tissues of very different natures, which, in truth, constitute the elements of these organs (l. c., lxxix.) The conception of a proper vitality is applicable only to these simple tissues, and not to the organs themselves (l. c., lxxxiv.).' And Bichat proceeds to make the obvious application of this doctrine of synthetic life, if I may so call it, to pathology. Since diseases are only alterations of vital properties, and the properties of each tissue are distinct from those of the rest, it is evident that the diseases of each tissue must be different from those of the rest. Therefore, in any organ composed of different tissues, one may be diseased and the other remain healthy, and this is what happens in most cases (l. c. lxxxv.). In a spirit of true prophecy, Bichat says: 'We have arrived at an epoch in which pathological anatomy should start afresh.' For, as the analysis of the organ had led him to the tissues as the physiological units of the organism, so, in a succeeding generation, the analysis of the tissues led to the cell as the physiological element of the tissues. The contemporaneous study of development brought out the same result, and the zoölogists and botanists, exploring the simplest and the lowest forms of animated beings, confirmed the great induction of the cell theory. Thus the apparently opposed views which have been battling with one another ever since the middle of the last century have proved to be each half a truth.

"The proposition of Descartes, that the body of a living man is a machine, the actions of which are explicable by the known laws of matter and motion, is unquestionably largely true. But it is also true that the living body is a synthesis of innumerable physiological elements, each of which may nearly be described in Wolff's words, as a fluid possessed of a *vis essentialis*, and a *solidescibilitas*; or, in modern phrase, as protoplasm susceptible of structural metamorphosis and functional metabolism; and that the only machinery, in the precise sense in which the Cartesian school understood mechanism, is that which co-ordinates and regulates these physiological units into an organic whole. In fact, the body is a machine of the nature of an army, not of that of a watch, or of a hydraulic apparatus. Of this army, each cell is a soldier, an organ a brigade, the central nervous system headquarters and field telegraph, the alimentary and circulatory system the commissariat. Losses are made good by recruits born in camp, and the life of the individual is a campaign, conducted successfully for a number of years, but with certain defeat in the long run.

"The efficacy of an army at any given moment depends on the health of the individual soldier, and on the perfection of the machinery by which he is led and brought into action at the proper time; and, therefore, if the analogy holds good, there can be only two kinds of diseases, the one dependent on abnormal states of the physiological units, the other on perturbation of their co-ordinating and alimentative machinery. Hence, the establishment of the cell theory in normal biology was swiftly followed by a 'cellular pathology' as its logical counterpart. I need not remind you how great an instrument of investigation this doctrine has proved in the hands of the man of genius, to whom its development is due, and who would probably be the last to forget that abnormal conditions of the co-ordinative and distributive machinery of the body are no less important factors of disease. Henceforward, as it appears to me, the connection of medicine with the biological sciences is clearly defined. Pure pathology is that branch of biology which defines the particular perturbation of cell-life, or of the co-ordinating machinery, or of both, on which the phenomena of disease depend.

"Those who are conversant with the present state of biology will hardly hesitate to admit that the conception of the life of one of the higher animals as the summation of the lives of a cell-aggregate, brought into harmonious action by a co-ordinative machinery formed by some of these cells, constitutes a permanent acquisition of physiological science. But the last form of the battle between the animistic and the physical views of life is seen in the contention whether the physical analysis of vital phenomena can be carried beyond this point or not.

"There are some to whom living protoplasm is a substance even such as Harvey conceived the blood to be, *summâ cum providentia et intellectu in finem certum agens, quasi ratiocinio quodam*; and who look, with as little favor as Bichat did, upon any attempt to apply the principles and the methods of physics and chemistry to the investigation of the vital processes of growth, metabolism, and contractility. They stand upon the ancient ways; only, in accordance with that progress toward democracy which a great political writer has declared to be the fatal characteristic of modern times, they substitute a republic formed by a few billion of 'animulæ' for the monarchy of the all-pervading 'anima.' Others, on the contrary, supported by a robust faith in the universal applicability of the principles laid down by Descartes, and seeing that the actions called 'vital' are, so far as we have any means of knowing, nothing but changes of place of particles of matter, look to molecular physics to achieve the analysis of the living protoplasm itself into a molecular mechanism. If there is any truth in the re-

* Anatomie générale, t., p. liv.

ceived doctrines of physics, that contrast between living and inert matter, on which Bichat lays so much stress, does not exist. In nature nothing is at rest, nothing is amorphous; the simplest particle of that which men in their blindness are pleased to call 'brute matter' is a vast aggregate of molecular mechanisms, performing complicated movements of immense rapidity, and sensitively adjusting themselves to every change in the surrounding world. Living matter differs from other matter in degree and not in kind; the microcosm repeats the macrocosm; and one chain of causation connects the nebulous original of suns and planetary systems with the protoplasmic foundation of life and organization. From this point of view pathology is the analogue of the theory of perturbations in astronomy; and therapeutics resolves itself into the discovery of the means by which a system of forces competent to eliminate any given perturbation may be introduced into the economy. And as pathology bases itself upon normal physiology, so therapeutics rests upon pharmacology, which is, strictly speaking, a part of the great biological topic of the influence of conditions on the living organism, and has no scientific foundation apart from physiology.

"It appears to me that there is no more hopeful indication of the progress of medicine toward the ideal of Descartes than is to be derived from a comparison of the state of pharmacology at the present day with that which existed forty years ago. If we consider the knowledge positively acquired in this short time of the *modus operandi* of urari, of atropia, of physostigmin, of veratria, of casca, of strychnia, of bromide of potassium, of phosphorus, there can surely be no ground for doubting that, sooner or later, the pharmacologist will supply the physician with the means of affecting, in any desired sense, the functions of any physiological element of the body. It will, in short, become possible to introduce into the economy a molecular mechanism which, like a very cunningly contrived torpedo, shall find its way to some particular group of living elements, and cause an explosion among them, leaving the rest untouched. The search for the explanation of diseased states in modified cell-life; the discovery of the important part played by parasitic organisms in the etiology of disease; the elucidation of the action of medicaments by the methods and the data of experimental physiology—appear to me to be the greatest steps which have ever been made toward the establishment of medicine on a scientific basis. I need hardly say they could not have been made except for the advance of normal biology.

"There can be no question, then, as to the nature or the value of the connection between medicine and the biological sciences. There can be no doubt that the future of pathology and of therapeutics, and therefore that of practical medicine, depend upon the extent to which those who occupy themselves with these subjects are trained in the methods, and impregnated with the fundamental truths, of biology.

"And, in conclusion, I venture to suggest that the collective sagacity of this Congress could occupy itself with no more important question than with this. How is medical education to be arranged, so that, without entangling the student in those details of the systematist which are valueless to him, he may be enabled to obtain a firm grasp of the great truths respecting animal and vegetable life, without which, notwithstanding all the progress of scientific medicine, he will still find himself an empiric?"

MISCELLANEOUS BUSINESS.

At the close of Professor Huxley's address, Mr. MacCormac followed with a statement, the most important items of which were that the number of members amounted to 3,210; that the sections had held 11 meetings, extending over 293 hours; that there had been delivered 464 written papers and 360 oral addresses. The attendance at the sections had been large, and had not shown signs of falling off even quite to the close. The museum was referred to as a great success, and the demonstrations of living patients had been attended by crowds each morning.

ENDORSING VIVISECTION.

Sir James Paget then presented the following resolution forwarded by Professor M. Foster, from the Physiological Section: "That this Congress records its conviction that experiments on living animals have proved of the utmost service to medicine in the past, and are indispensable for its future progress; that accordingly, whilst strongly deprecating the infliction of unnecessary pain, it is of opinion that, in the interests of men and animals, it is not desirable to restrict competent persons in the performance of such experiments." Pointing out that it was impossible to discuss such a resolution then, the President asked those who were opposed to it to record their names and votes at the close of the meeting. The resolution was then adopted with loud cheers, and no hand was held up in opposition to it.

TESTS FOR COLOR-BLINDNESS.

A resolution received from the Ophthalmological Section, on the subject of the tests most applicable to be employed in working and observing signals by land or sea where the lives of others are involved, was similarly carried unanimously, and the recommendations of the section ordered to be forwarded by the Hon. Secretary-General as the opinion of the Congress to the Foreign Secretary, the First Lord of the Admiralty, and the President of the Board of Trade.

MEDALS OF HONOR.

Mr. Bowman moved, and Professor Lister seconded, a resolution presenting a medal of honor to Professor Donders (President of last Congress), Dr. Guy (Hon. Secretary-General of last Congress), to Madame Raynaud, as a souvenir of the high part her husband was to have taken, and to the readers of the general addresses, Professor Virchow, Dr. Féréol, Dr. Billings, Professors Volkmann, Pasteur, and Huxley. This resolution was carried by acclamation, and Sir James Paget then presented the medals, requesting Professor von Langenbeck to receive Professor Virchow's, and Professor Charcot Madame Reynaud's and Dr. Féréol's.

A vote of thanks to those who, not being members of the Congress, had so largely aided in making the meeting a success, was moved by Professor von Langenbeck and Mr. Prescott Hewett; and a similar vote to Mr. Makins and his coadjutors, Messrs. Cowell and Little, and the permanent members of the staff of the Honorary Secretary-General, was moved by Dr. Guy and Sir R. Bennett, and carried with loud cheers. The part that these gentlemen have taken, and especially Mr. Makins, has not been conspicuous, but those who have been engaged in the working of the Congress know to how large an extent its success is due to their business capacity and untiring energy; Mr.

MacCormac is to be congratulated on having received such assistance.

CONCLUDING EXERCISES.

The selection of the next place of meeting was referred to the Executive Committee, and it was stated that invitations had been received from the King of Spain, from Copenhagen, Stockholm, and Christiania. A vote of thanks to Mr. MacCormac for his very efficient services was moved by Drs. Billings and Guéneau de Mussy, and the reception which this resolution met with from every member present must have been in the highest degree gratifying to Mr. MacCormac, and in some measure a reward for long-continued, arduous, and self-denying labors on their behalf. M. Charcot and Professor Donders moved the last resolution, thanking Sir J. Paget for his highly efficient conduct in the chair. This resolution was carried with enthusiasm, and the whole meeting rose and cheered the President. In a few words, which formed an apt conclusion of a week's work in which he has distinguished himself equally by his business capacity, his eloquence and graceful and lavish hospitality, Sir James Paget closed the meeting, wishing all "good-bye," and expressed the hope that their "good-being" might come from its highest possible source—well-doing, and the Great International Medical Congress of 1881 was dissolved.

---

THE SOCIAL ENTERTAINMENTS.

On Thursday, August 4th, the Lord Mayor entertained a party of nearly three hundred at dinner at the Mansion House. The foreigners present included von Langenbeck, Donders, Billings, Pasteur, Flint, Kuster, Büsch, Klebs, Corneil, Brown-Séquard, Bigelow, Gerhardt, Hardy, His, Pantaleoni, Charcot, Esmarch, Brandis, Ollier, Tarnier, Verneuil, Parrot, Ranke, and many others. In proposing the toast of the International Medical Congress, the Lord Mayor spoke of the great pleasure it gave him to welcome such a distinguished company to the Mansion House; amidst an age of congresses, none had yet assembled which promised to have more important results than the one he then entertained, composed so largely of men distinguished for their scientific research, high intellectual gifts, and fruitful labors. Sir James Paget replied, and assured the Lord Mayor that although in science they looked for constant change, none had a higher regard for the institutions representing permanence, such as that whose hospitality they were then enjoying, than the doctors. In response to the toast of the Foreign Guests, proposed by the Lord Mayor, Professor Langenbeck expressed his warmest thanks for that magnificent banquet, and said that none would ever forget the happy days they had been allowed to spend in London.

Professor Trélat spoke of the hospitality he and all had received, and of the great improvements that had taken place in London during the last thirty years. Professor Pantaleoni referred to his visit to London in 1851, and the great changes that he saw now. He thought England deserved to be free and prosperous, for she has respected the liberties and aims of others. English science had always had the characteristic of being practical and certain, and he believed it was as distinguished for this to-day as ever. Dr. Austin Flint thought the Meeting of Congress would greatly increase the affection of the daughter or the mother-country, and that there would soon be such an exodus from America to London, that to cure it the Congress would have to meet in New York. Professor Donders, in proposing the health of the Lord Mayor, said that he came to London with great expectations, but that the reception and all the arrangements had far surpassed all he had pictured; and that evening was the climax, for the City of London acknowledged the real value of medical science to humanity.

On Friday, a lunch was given by Dr. Broadbent, President of the Medical Society of London, in the Society's Rooms, to the Honorary Fellows recently admitted and to the Council of the Society. After the lunch, Dr. Broadbent presented the diplomas to each of the distinguished Fellows in turn, introducing each in a few well chosen words. Those present were: Dr. Billings, Dr. Bigelow, Professor Charcot, Dr. Emmet, Professor Halla, Professor Tarnier, Professor Verneuil, and Professor Volkmann. Short speeches were afterward made by Professors Virchow, Charcot, Volkman, Verneuil, and Dr. Billings, and the guests quickly dispersed to the various sections with the general feeling that they had shared in one of the most successful of all the entertainments of the week. In the evening the Corporation of the City of London gave a brilliant conversazione at the Guildhall, which was attended by over three thousand five hundred persons, including all the foreign members of the Congress. The old hall itself was beautifully decorated with choice flowers, the library, council-chamber, museum, and every available room being opened and decorated. The Lord Mayor and Lady Mayoress received the guests on their arrival. The plate of the Corporation and City Companies was shown in one of the rooms, and made a splendid display; in the library many rare literary and art treasures were exposed, and the museum, of course, contained numerous objects of rare interest. Two military bands, and a concert of vocal music, contributed to the pleasure of the evening, and there was a liberal supply of man's more material wants in the crypt. The rooms were lighted by the electric light, the Swann and the Maxim lights being tried in places, the latter being supplied with electricity from storage batteries. Altogether, this reception was a most brilliant success.

Saturday was a half-holiday, the afternoon being given up to excursions and garden-parties. Several hundred ladies and gentlemen accepted Mr. and Mrs. Spencer Wells' invitation to a garden-party at Hampstead, where there was every provision that nature and hospitality could provide. About one thousand went by water or rail to Normansfield, at Dr. and Mrs. Langdon Down's invitation. A large party was taken over Hampton Court Palace by Dr. Down on their way to Hampton Wick. In addition to the beautiful grounds, all the institution was open to inspection. As is well known, every effort has been made by Dr. Down, with the able help of Mr. Plumbe, his architect, to make his house as complete in all its arrangements as can be, and they have succeeded in supplying every provision for the safety, comfort, enjoyment, and instruction of those entrusted to their care. About three hundred guests, including the President of the Congress, visited Fairlawn, Wimbledon Common, the residence of Mr. Saunders, President of the Section on Diseases of the Teeth. The beautiful grounds were in splendid condition, and the afternoon was greatly enjoyed. The Hungarian Band played in the garden.

Another party was received by Sir J. D. Hooker,

at Kew Gardens. Dr. A. Carpenter conducted a large number of the members of the Congress over the Sewage Farm at Croydon, which was most thoroughly and satisfactorily explored. They were then entertained at lunch in the interesting old hall at Beddington, and the very fine vegetables and fruit were a practical test of the productive capacity of the farm. The United Hospitals (Guy's and St. Thomas's) Club asked a party to dine with them at the Star and Garter Hotel, Richmond, and about seventy sat down to an excellent dinner. Mr. Bryant occupied the chair, and the guests included Drs. Charcot, Verneuil, Billings, Blandis, Liman, Lancereaux, Erb, Hueter, Sayre, Sir H. Thompson, Mr. Holden, and many others. Those of the guests who spoke, referred in warm terms not only to that act of hospitality, but to the remarkable success of the whole meeting, and to the warmth of the welcome they had received on all sides. Later in the evening the Countess Granville gave a reception, to which many members of the Congress were honored with invitations. Among those present were the ambassadors of the courts of Turkey, Italy, France, Spain, Portugal, Belgium, and the Netherlands, Sir James and Lady Paget, Sir R. and Lady Bennett, Drs. Dujardin-Beaumetz, Oscar Simon, Minis Hays, Trélaz, Andrew Clark, Albanese, De Mussy, Rothe, Brunton, Angelucci, Bigelow, Axel, Krebs, Vidal, Pavy, Rees, Volkmann, Battey, Martin, Maclagan, Ollier, Allen Thompson, and many others.

On Monday evening, the Master and Wardens of the Society of Apothecaries entertained at dinner a select company of about one hundred and twenty at their ancient hall at Blackfriars. The tables were profusely decorated, and the dinner one of the highest excellence, with very choice wines. Among the foreign guests we noticed Drs. Esmarch, Billings, Volkmann, Ball, Lancereaux, Goltz, Hardy, Krause, Worms, Eulenberg, Simon, Warlomont, Küster, Frericus, G. de Mussy, Chauveau, Carl Reyher, Erb, and Czerny. The toasts of the foreign visitors were responded to by Dr. Worms, Professor Esmarch, and Dr. Billings, Dr. Quain, Mr. Lister, and Sir H. Thompson. In the evening the whole Congress was invited to a conversazione at the College of Surgeons, which was largely attended. The museum was illuminated by the electric light, which, to some tastes, had a somewhat ghastly effect; whether it was the coming at the end of such a long and brilliant series of entertainments, with the consequent ennui, or the absence of ladies and some of the more brilliant adjuncts of other soirees we know not, but the evening was not such a striking success as some of the former. On Tuesday a large number of the members of the Congress, with their friends, dined informally at the Crystal Palace, and afterward witnessed a fine display of fireworks. The informality and ease of the meeting, and possibly also a sense of relief at having reached the end of what was a very hard week for all engaged in it, contributed to make this jovial gathering a very successful one.

---

OUR REPORT OF THE CONGRESS.

We regret to say that we shall be unable, on account of the quantity of valuable material accumulated by the meetings of the Sections, to conclude our report of the Congress. We have been compelled to crowd out several reports of Sections, together with the address of Prof. Volkmann, which we hope to publish in our next issue.

## MEETINGS OF THE SECTIONS.

### SECTION ON ANATOMY.

The first business meeting in the Section of Anatomy was held on Thursday morning, the 4th inst., when an introductory address on "The Museum of the Royal College of Surgeons" was delivered by the President of the Section, Prof. Flower, F.R.S. Amongst the audience were noticed many foreign anatomists of eminence, such as Kölliker, His, Braune, Hannover, Toldt, Carruccio, Räbl-Rückhard, as well as nearly all the well-known representatives of British anatomical science—Turner, Struthers, Macalister, Humphry, Parker, Allen Thomson, Holden, etc. The subsequent sectional meetings were regularly attended by all these gentlemen, and the papers and discussions were of considerable value and interest. After the introductory address, a vote of thanks to Prof. Flower was moved by Dr. Allen Thomson, and seconded, in a few well-chosen sentences in English, by Prof. Kölliker.

THE NORMAL CHARACTERS OF THE HUMAN EMBRYO.

Prof. His (Leipsic) brought forward the very important proposition that "The Number of Embryos which have been Described, are Sufficient for Anatomists to Determine what are the Normal Characters of the Human Embryo, and that Probably in no Normal Embryo is there ever a Free Vesicular Allantois." Prof. His described his embryonic preparations at some length, and showed some beautiful wax-models and stereoscopic-slides in illustration of his remarks; Dr. Allen Thomson considered that the proposition was rather premature, inasmuch as some of the embryos mentioned were undoubtedly pathological, as most abortions must necessarily be. Dr. Thomson, as well as most of the other anatomists present, thought that there was more variability in the amount of attachment of the allantois to the chorion than Prof. His had stated. In fact, the general conclusion of the meeting seemed to be that further specimens must be carefully examined before such a general proposition as that of Prof. His could be adopted. The remainder of the sitting was devoted to a discussion on the characteristics of

HUMAN CRANIA IN RELATION TO RACE,

and was introduced by Prof. Turner in a paper "On the Cranial Characters of the Natives of the Admiralty Islands." The skulls described were eleven complete and one calvaria, all adults: seven males and five females. They were smeared with a red pigment, and one had an artificial nose and eyes modelled in a black material. They had been obtained in March, 1875, by the scientific staff of the Challenger, and entrusted to Prof. Turner for description. The crania were markedly delichocephalic (somewhat higher than broad), and while the females were microcephalic in capacity, the males were mesocephalic, there being a difference of about two hundred and fifty cubic centimetres between the two sexes. They approximated very nearly to the skulls obtained from the people inhabiting the coast-line of New Guinea. In the subsequent discussion, Prof. Flower pointed out the increasing value of such complete cranial descriptions in reference to the determination of races in places where there had been little, if any, admixture with foreign nations, and Dr. Räbl-Rückhard, of Berlin, gave a short account of forty-two

skulls from New Britain, which had been collected during a German expedition to the Kerguelen Island. One point of interest was that these skulls, although coming from an island much nearer to the Admiralty Islands than to Australia, bore a greater resemblance to the Australian type than to those described by Prof. Turner. Profs. Toldt (Prague) and Lesshaft (St. Petersburg) joined in a most interesting anthropological conversation, the latter referring especially to twenty-five Kalmuck skulls which he had examined.

### THE SUPRA-CONDYLOID PROCESS AND HEREDITARY TRANSMISSION.

On Friday, Professor Struthers described minutely a series of dry and wet specimens, showing a supra-condyloid process. He showed that, although well known to every anatomist in its ordinary form, when it is also of great importance to the operating surgeon, it had been overlooked in its rudimentary condition, which he had found to exist normally in every human subject which he had examined. In these cases it is found as a band or bands of fibres beneath the brachialis anticus muscle. A striking instance of its hereditary transmission was next described, and the theory of descent referred to as the only explanation of its presence, occurring as it does so widely amongst mammalia, from the ornithorhynchus paradoxus upward to man; in the latter no teleological explanation was available. Professor Flower pointed out that the very variability of this process in the mammalia was in favor of its being transmitted by descent. It may be casually remarked, that in the subsequent discussion all the anatomists who spoke, regarded the evolution theory as the only possible hypothesis for the explanation of the occurrence of this and similar structures, and no one even ventured on a teleological argument.

### THE POSITION OF THE STOMACH.

Professor Lesshaft next read two papers: 1st, "On the Causes which Determine the Shape of the Bones, Illustrated by Numerous Specimens from Man and the Lower Animals;" and, 2d, "On the Position of the Stomach." He considered that this organ is placed more vertically than is generally supposed, but its oblique position, as shown in Dursy's model, made under the supervision of Luschka, was strenuously maintained by Professors His, Kölliker, and Braune, and by Mr. Holden, who all agreed that a vertical stomach only existed in the young child. Dr. Laura, of Turin, read two papers on the minute structure of the spinal cord and medulla oblongata. Professor Adamkiewicz, of Cracow, made a short communication of the minute vessels of the spinal cord, and Professor Léon Tripier, of Lyons, showed some anatomical transparent preparations of sections of the limbs, and described his method of preparing and mounting them. These gentlemen exhibited their specimens and gave a further demonstration in the museum in the afternoon.

### CRANIAL MEASUREMENTS AND THE PRIMORDIAL CARTILAGE OF THE HUMAN SKULL.

On Saturday, the subject of cranial measurements was again brought forward by Professor Benedikt of Vienna, who described a new method of measurement by means of an instrument which he had invented, and showed some drawings which he had made with it. Professor Hannover, of Copenhagen, next gave a most lucid and interesting account, in English, of the primordial cartilage of the human skull, and showed several embryonic cartilaginous crania, and some special preparations, demonstrating that Meckel's cartilages do not unite in the median line as is generally supposed, but that they are separated by a slight interval, and terminate in a hooked extremity; and Professor Redfern made a few remarks on the insignificance of the question as to whether ossification is preceded by cartilage, or takes place in an original fibrous membrane.

### THE NERVE-SUPPLY AND HOMOLOGY OF MUSCLES IN DIFFERENT ANIMALS.

Another very important communication was read by Dr. Cunningham, of Edinburgh, on the importance of the nerve-supply in determining the homology of muscles in different animals. He considered that attention should be given thereto, as well as to their attachments, but could not go so far as to accept the position of Dr. Ruge, of Heidelberg, who has recently asserted that the nerve-supply is an infallible guide in determining these questions. Professors Macalister, Kölliker, Struthers, Turner, and Mr. Forbes took part in the discussion, and showed that the segmentation of the primitive muscle-masses was so very different in different animals, that questions of homological relationship were very difficult to make certain of, and required great caution in handling, although their study was most interesting and captivating. Dr. Fasebeck, of Brunswick, gave a short description of some exquisite dissections which he had made to prove the independence of the small or motor portion of the fifth nerve, and Dr. Howard pointed out the anatomical mechanism by which a post-oral passage may be secured for the entrance of air into the lungs in cases of threatened apnœa.

### THE FORMATION OF THE EMBRYONIC MESODERM.

On resuming the business of the section on Monday, Professor Kölliker gave an excellent *résumé*, in English, of his views on the formation of the embryonic mesoderm, as seen by him in the rabbit. In this animal he had clearly traced its derivation from the cells of the ectoderm, but thought that it might arise differently in different animals, and so in some cases be derived from the endoderm, as described by some other embryologists. Even at the earliest periods the cells of the mesoderm resemble connective-tissue corpuscles, and not epithelial cells, although subsequently in certain places they may be transformed into the latter. Professors His, Schäfer, and Allen Thomson took part in the discussion, after which Professor Kölliker, in response to a request made by Professor Turner, explained his view of the formation of the chorda dorsalis from the mesoderm, and not from the endoderm as is often supposed. Professor Kölliker exhibited some specimens of embryos in support of his views, and illustrated his communication by some remarkably clear drawings on the black-board, as he proceeded with his remarks.

### THE HUMAN INTERMAXILLARY BONE.

The Professor next made a communication on behalf of his son, Dr. Theodore Kölliker, "On the Human Intermaxillary Bone." Dr. Kölliker had demonstrated its separate existence in fœtuses of eight weeks old, but at the end of the ninth week it was always fused with the superior maxilla. The number of teeth in the intermaxillary bone was not constant.

THE SUBCUTANEOUS VEINS OF THE TRUNK.

Mr. Fenwick then gave a most interesting account of the subcutaneous veins of the trunk as dissected by him under the supervision of Professor Braune of Leipsic. He stated that he had been obliged to make as many as five hundred or six hundred injections in order to fill the system completely. They might be divided into three zones: an upper zone running into the axillary vein, a lower zone into the femoral, and an intermediate zone, destitute of valves, emptying itself indiscriminately into either of the other sets. The communication between the portal system and the epigastric veins, by means of Sappey's vein in the round ligament of the liver, was also shown. Professor Braune referred to the pump-like action on the venous circulation of the movements of the fasciæ at the points where the veins pass through, and to the arrangement of the valves at these points. The remainder of the session was occupied with a spirited discussion on "Anatomical Teaching," introduced by a paper by Professor Struthers, comparing the British and Continental Schools, and another by Professor Keen, of Philadelphia, on the advantages of a systematic use of the living subject in facilitating anatomical study.

THE CEREBRAL SINUSES AND THEIR VARIATIONS.

On Tuesday, Mr. Knott, of Dublin, began with an exhaustive account of "The Cerebral Blood-Sinuses and their Variations." Deviations were frequently found, and their details in forty-four skulls examined carefully with a view to relative frequency were laid before the session.

Dr. Gasson read a paper on "Pelvic Measurements," with a view to determining which are the most important for the purpose of comparing the pelves of different races. He thought that transverse measurements at the brim form a better standard than antero-posterior. Comparative measurements of the pelves of fourteen European females, five Australians, and thirteen Andamanese were given in illustration. Professors Turner, Thane, and Braune suggested other measurements as being also of proved utility.

Two important papers on "Development" were read by Drs. Rein and Lebedeff of St. Petersburg. Dr. Rein (in the course of an elaborate memoir on the mammary gland) took exception to Dr. Creighton's description of the surrounding fat-tissue taking any part in the formation of the parenchyma of the gland, and did not confirm Gegenbaur's statement of the peculiar mode of the formation of the nipple in ruminants.

Professor Sapolini, of Milan, described as a thirteenth cranial nerve the origin of the portio-intermedia of Wrisberg from the brain, and traced it into the chorda tympani; and Professor Hannover gave a demonstration of the funiculus scleroticæ—the remains of the primitive fetal fissure—in the human eye.

The business of the section being finished, Professors Braune and His, in very eulogistic terms, thanked the officers of the section for their courtesy and the excellent arrangement of the work, and the session terminated.

## SECTION ON SURGERY.

This section was well attended throughout, and worked very hard, having prolonged its meetings beyond the time fixed. But what has enabled the section to compass nearly all the work proposed has been the admirable manner in which the wise rules of debate have been courteously, but firmly, carried out by the President.

THE TREATMENT OF ANEURISM BY THE ELASTIC BANDAGE.

After the address of the President, Staff-Surgeon Reid, who was the first to treat aneurism by Esmarch's elastic bandage, opened a discussion on this subject with a paper recording his own cases, and pointing out that sacculated aneurisms were the only ones suited for this treatment, which cured the aneurism by causing coagulation of the whole mass of blood in the sac. Mr. Pearce Gould followed much on the same lines; he gave a table of sixty-two published cases in which this treatment had been employed, and from this he drew the conclusion that the more important element in the cure is the organization of the clot in the artery itself, and that failure may result either from the blood not clotting at all, or from washing away the clot first formed. He further pointed out that the danger of over-distending the other arteries, or of overtaxing a weakened heart, ought to be guarded against, and that preparatory treatment to increase the plasticity of the blood was desirable. Mr. Bryant referred to three cases in which he had failed to cure the aneurism, and regarded the capillary hemorrhages in the part of the limb not emptied of blood as liable to lead to gangrene. Mr. Pemberton related a case, fatal from gangrene, where it was found that the vein was completely obliterated opposite the aneurism, which was occluded with coagulum. It is difficult to accept Mr. Bryant's view; even admitting the facts to be as he states, capillary hemorrhage in the ham cannot cause gangrene of the toes, and obviously there can be no capillary hemorrhage in the parts emptied of blood by the bandage. Mr. Pemberton's case had, of course, no special bearing upon this form of treatment; the same result would have followed occlusion of the main artery by other means; for with the arterial flow obstructed, interference with the venous return is one of the best-recognized causes of gangrene. This subject, then, remains much where it was. The table of cases circulated may stimulate inquiry, and the pathology of the method which Mr. Gould has briefly discussed before, he has now more fully elucidated.

THE SURGICAL TREATMENT OF INTRA-PERITONEAL TUMORS.

Mr. Spencer Wells opened the discussion on recent advances in the surgical treatment of intra-peritoneal tumors, and the points upon which he laid stress were the necessity for union of the edges, or rather surfaces, of the cut peritoneum, so as to insure immediate union; the great value of pressure-forceps for the control of hemorrhage; and the fact that the use of antiseptics has done away with the need for drainage. During the last three years he had not used drainage once, though he thought two or three patients had died who might have been saved by it. Dr. Marion Sims strongly advocated drainage, though admitting it often led to ventral hernia, while Drs. Keith, Thornton, and Martin advocated it for severe operations only, and in cases of cysts with putrid contents. In reference to removal of uterine tumors, in addition to the citation of interesting cases by several speakers, the main outcome of the discussion was, that the operation was rendered safer and attended with less loss of blood when the tumor could be raised out of the womb

and enveloped in an elastic bandage. The careful closure of both the uterine and the peritoneal cavities, where both were opened, was insisted on; Mr. Thornton pointed out the great difficulty of rendering the uterine cavity aseptic; and the use of the elastic ligature for the pedicle was advocated. The antiseptic method had many warm supporters, but Dr. Keith stated that with it, after having a succession of eighty successful cases, he had five deaths in the next twenty-five cases: two from carbolic-poisoning, one from septicæmia, and two from acute nephritis. On account of this mortality, and of the very frequent high temperature the evening after the operation, he had abandoned the spray in all operations, and had only had one death out of twenty-seven ovariotomies without the antiseptic treatment. Professor Czerny related a successful case of excision of the pylorus; and Mr. Tait referred to his experience in abdominal surgery, to show how the domain for surgical interference is extending to pelvic abscesses, etc. Of all the many surgical improvements of the last thirty years, there is none that can take a higher rank than this, and it appears that we have not yet learned the full extent of its value, or appreciated the degree to which the peritoneal cavity can be interfered with without a disproportionate danger.

NEPHROTOMY—NEPHRO-LITHOTOMY AND NEPHRECTOMY.

The question of surgical interference with the kidney was raised and discussed by Czerny, Baker, Barker, Barwell, Lucas, Martin, and Langenbeck. All had cases of nephrotomy, nephro-lithotomy, or nephrectomy to relate, and Dr. Martin stated that he had seven times removed a painful floating kidney, and once a malignant tumor of the kidney, with five recoveries in all. To aid the diagnosis of renal conditions, Mr. Barker suggested that in stone the kidney should be exposed from the loin and carefully explored with a needle, and the President considered the suggestion valuable. The difficulty of deciding whether pyelitis or suppurating sacculated kidney is unilateral or bilateral, is a strong argument against performing such a severe operation as nephrectomy without being sure of removing the entire disease, and until diagnosis has advanced the application of this treatment, it must be very limited. The excellent cases recorded show the feasibility of the three operations named above, and, so far as they may be taken as a guide, prove that nephrectomy is not more dangerous to life than nephro-lithotomy and nephrotomy. Three methods of removal of the kidney were described: the lumbar, the intra-peritoneal, and the abdominal extra-peritoneal. The first would seem to be at once the most difficult and the safest; but Dr. Martin states that, in removal of the kidney from the front of the belly, the peritoneum falls together so completely that it does not even require stitching. A decision on this point must follow the more accurate diagnosis of the precise conditions in which removal of one of the kidneys is justifiable; it is on this point that most light is required at present. No detailed information was given of the physiological effects of removal of one kidney.

THE RECENT ADVANCES IN THE METHODS OF EXTRACTING STONE FROM THE BLADDER.

The next discussion was raised on the recent advances in the methods of extracting stone from the bladder of the male, and was opened by Sir H. Thompson in a very able paper, continued by Professor Bigelow, and joined in by most of the leading authorities on this subject. The question naturally divides into two—lithotomy and lithotrity. As to the former, the only novelty proposed was the use of the thermo-cautery instead of the knife in both perineal and, especially, supra-pubic lithotomy, with the view of avoiding hemorrhage and having a dry, non-absorbent wound. The objections to this plan are so obvious, viz.: the formation of a deep slough, the inability to follow the exact steps of the operation and regulate the amount of damage—that they only require to be stated. More valuable were Mr. Teale's remarks on the improved results of lithotomy in late years, owing to the avoidance of septic diseases, and the greater deliberation in the extraction of the stone—a point always most important to bear in mind, for in this case rapid operating is not only uncalled for, but mischievous. Dr. G. Buchanan advocated the use of the rectangular staff, which makes the operation easier and safer; but Professor Spence, whilst praising it, pointed out that in cases of very large prostates its point may not reach the bladder, and so lead to trouble. Sir H. Thompson spoke hopefully of the plan of crushing a very large calculus *in situ* by powerful forceps before opening the bladder, and recommended a combination of lithotrity with an opening into the membranous urethra from the perineum in cases of greatly enlarged prostate, with irritable bladder and urethra.

As regards lithotrity, it was admitted by all that Professor Bigelow had not only introduced a new principle into the operation by insisting on the axiom that the bladder was more tolerant of instruments than of sharp fragments of stone, but that his practice was also an improvement. Out of ninety-one cases operated on after this plan by Sir H. Thompson, eighty-eight recovered. Beyond this, however, there was no agreement. Bigelow insists on the value of large instruments, even for small and moderate-sized stones, and that his operation is suited for all cases of lithotrity. Sir H. Thompson is as earnest in contending that the instruments should be proportionate to the size and hardness of the stone, and never larger than necessary; while Mr. B. Hill thinks that there are many cases in which the old operation is better, the danger in injuring the deeper parts of the urethra in men of adult middle age being important. Mr. Teevan spoke of the entire absence of chronic cystitis after Bigelow's operation. As to whether the new operation has enlarged the field of lithotrity, Mr. Coulson spoke of having removed four ounces of stone at one sitting; Sir H. Thompson showed the *débris* of large stones thus removed, and the results of Bigelow's practice are well known; Mr. Teale and Dr. Buchanan concurred in the belief that, except to the practiced lithotritist, such was not the case, and that the lithotrite could not be used with more safety for a larger stone now than formerly, and that, whenever doubt existed, it was safer to lithotomize. Professor Bigelow showed his latest improvements in the lithotrite—a new simple catch—and in the exhausting bottle, the chief features of which are a hose attached to the top of the bottle to admit water or to give exit to air during the operation, and a new valve and trap at the junction of the catheter and exhausting tube to catch all the dust and fragments that in the ordinary way pass to and fro in the tube, and so delay the evacuation. This is no doubt a direction in which improvement is needed, but it is a question whether this trap or Mr. Clover's original

simple contrivance be the better for the purpose. There is much in Mr. B. Browne's observation of the great desirability of keeping surgical apparatus as free from complications as possible. Dr. Bigelow, at the close of the meeting, gave a very interesting demonstration of the use of his apparatus, and it must have been gratifying to him to find that among the differences of opinion on other points, all were agreed in ascribing to him the full credit of his principle of practice, both for its novelty and its value.

EXCISION OF JOINTS.

To M. Ollier was allotted the task of introducing the subject of "Excision of Joints," and he laid stress on the value of the subperiosteal plan, and stated that when properly carried out, even the cartilage might be regenerated in the new joint—he preferred early to late excision. M. Rocher, of Berne, followed with his statistics of sixty-four cases of excision with six deaths—he has recently tried to obtain a movable knee-joint after excision. Mr. Newman related a very excellent case where drainage of the joint was successful in acute arthritis subsequent to disease of the head of the tibia. But the real question at issue was as to the desirability of the operation early or late in the disease. Mr. Bryant, Mr. Heath, and Mr. Marsh strongly advocated a limited use of the operation; they regard the disease as local, and as locally curable, and therefore consider excision out of place except after all other methods have failed, and in advanced disease. On the other hand, all were agreed that in such cases the results of excision have been most disheartening; and for this reason, and also because of the shortening of the total period of pain and illness, and of the connection of the local disease with general disease, others—Messrs. Crott, Teale, Treves, and Barton—recommend an early resort to the operation. The arguments urged on each side are, no doubt, well worthy of full consideration; it is, however, for those who operate to demonstrate the necessity for the practice. It is impossible not to see that those who urge operation very early will be led to operate when not necessary, as errors in diagnosis will occur to all; and further, such a practice will tend to draw attention from the main requisite—a mode of cure of the disease. Perhaps hardly sufficient stress was laid upon the excellent results given by free incision into chronically diseased joints. We should mention that Dr. Sayre showed drawings of a case of singularly perfect reformation of the hip-joint after excision; new cartilage was present.

PRIMARY UNION IN OPERATION WOUNDS, AND THE ANTISEPTIC TREATMENT.

The most important and best sustained of all the discussions took place on Monday, August 9th, on "The Causes of Failure in Obtaining Primary Union in Operation Wounds, and on the Methods Best Calculated to Secure it." Mr. Savory opened in a very eloquent and philosophic speech, pointing out that primary union was most likely to occur when fresh surfaces are brought together in their natural state, and maintained so without disturbance. The chief cause of failure he believed to be "meddlesome surgery," and essential principles were rest, cleanliness, and asepsis, which admit of almost endless variation in detail. He asked, when a wound was septic or aseptic, was fever, or pus, or only smell, to be the criterion? Defending his Cork statistics, he claimed that they had not been surpassed, though equally good results were obtained by many different plans of treatment, the actual processes of healing being primarily independent of them all.

Mr. S. Gamgee followed, and showed the antiseptic absorbent cotton-pads he has used with success. As one proof of their antiseptic power, he showed a piece of meat which had been lying between two of them, but exposed to the air for fifteen seconds every day, and was perfectly sweet at the end of twelve days. The principles he laid stress upon were perfect dryness of the wound, thus removing one of the conditions of putrefaction; rest, and infrequent change of dressing; circular compression, and suitable position, with the use of antiseptics as an important adjunct.

Dr. Humphrey spoke of the importance of a clean-cut wound in healthy tissues, very accurate apposition of the edges and surfaces, with very careful closure of all bleeding vessels. The air acting injuriously both as a direct depressant of the vitality of the tissues, and through floating agents, it was only wise to use some form of antiseptic to purify the air.

Professor Verneuil considers that the disposition of the wound, and of the patient, are the great factors in the healing process. Professor Esmarch's statistics of his own practice are so remarkable, that it is necessary to give them in full. In 398 great operations (6 deaths) eighty-five per cent. of the cases cured, healed by first intention with one dressing, in fifteen per cent. the dressing was renewed—and this ratio had improved of late. There were 146 excisions of large tumors; 40 excisions of mammæ, and axillary glands; 14 castrations, with 1 death from pericarditis and old syphilis, 1 from apoplexy, 1 from fatty heart. Of 51 major amputations (thigh 18, leg 27, arm 5, forearm 1), 1 died from shock and hemorrhage, and 1 from delirium tremens. There were 61 resections; 11 exarticulations; 26 necrotomies; 13 nerve-stretchings, 1 for tetanus, which was fatal; 8 hernias; 21 large cold abscesses; 12 large wounds; 49 compound fractures. The cases were all dressed with pads soaked in iodoform and absolute alchohol (ten per cent.), fastened on by an iodoform bandage, over that a large pillow of jute and gauze, a moist bandage, and over all an elastic bandage. Professor Volkmann thought that all suppuration is septic, and that personal peculiarity in the main had nothing to do with the healing of a wound. Other evidence was offered and opinions given which only corroborated the above, and supported various ways of carrying out a dry dressing, with rest and compression combined with antiseptics, as advocated by Mr. Gamgee, whose labors in this direction have perhaps not been sufficiently recognized.

Professor Lister wound up the discussion. In reference to Dr. Keith's experience, he stated that he had dissuaded him from using antiseptics in the first instance; in such an operation there is abundant room for effusion and means of absorption, while carbolic acid both increases the one and lessens the other; but on the whole he thought antiseptic ovariotomy had been successful. Referring to the experiments detailed at Cambridge, which showed that diluted septic poison may be added without effect to blood-serum, though not to diluted blood-serum, he further recited more recent experiments which showed that blood-clot in the body is still less favorable to the development of organisms. He expressed his belief that it is "solid bits of dirt" that are the deleterious agents, and that possibly

too much attention has been paid to the finest particles floating in the air. His own results, however, were so good, that he shrank from giving up any one of the details of the treatment by which he obtained them, although he quite admitted that he too might at some future time be able to say *fort mit dem spray;* at present he could not accept irrigation as a substitute for the spray. He denied that there was any ground for the charge that he disregarded the general condition of the patient or his hygienic surroundings. Were this true, his results being so good, as admitted by all, what a strong argument it afforded to the efficacy of his merely local treatment! There was no time for Professor Lister to touch upon the many points raised by previous speakers. If we were to attempt to give in a few words the general impression produced by the debate, we should say that the value of antiseptics was clearly recognized by all; that it was made evident that Professor Lister's aim may be attained by means other and simpler than his; that in particular the value of the spray is considered very doubtful; but more than all, that antiseptic treatment only answers one of the requirements of wound-treatment, and that he only is a scientific surgeon who enlarges his views and practice to embrace all.

SYPHILIS IN TUBERCULOUS AND GOUTY CONSTITUTIONS.

The final discussion was on the modifications of syphilis in tuberculous, gouty, and other constitutions, and was opened by M. Verneuil, who maintained that scrofula attracts syphilis to the organs it most commonly itself affects, and is apt to cause suppuration, but to remove the element of pain. Tuberculosis makes some tertiary syphilitic manifestations persist indefinitely. Mr. Hutchinson had never seen a hybrid of syphilis and struma or tubercle or gout, nor had he been able to trace any modification of syphilis by these diseases, although the variations met with were no doubt to be explained by the idiosyncrasies of the patients. The antecedents of a patient did not enable him to predicate anything of the course of the acquired disease. In gouty patients he had often noticed severe bone and joint pains. He thought, however, that a severe form of ulceration of the face, closely resembling lupus, was to be accounted for by the influence of struma on inherited syphilis. Dr. Bennett knew of no modifications of rickety, gouty, or other bone changes that could be traced to syphilis, and he referred to the absence of information on the syphilitic changes in joints. Dr. Drysdale spoke to the existence of syphilitic phthisis from gummatous change. But so far as the discussion may be taken as a criterion of professional knowledge, no satisfactory evidence of syphilitic hybridism, or of marked modification of syphilis by any other dyscrasia, has been demonstrated.

## SECTION ON MEDICINE.

Sir W. Gull, in his presidential address, singled out the chief topics that would be discussed, and following in his lines we may most conveniently convey an idea of the nature and quality of these topics by treating them in groups, and dwelling, so far as our limited space will permit, on the main points debated. In the earlier portion of his address the President had sketched out the share taken by each nation in the early development of medical science, and the proceedings of the section reflected fairly well the different nationalities comprising the Congress, and several papers were read and speeches made in the French and German tongues. The disease of the nervous system which had the largest share of attention bestowed upon it was locomotor ataxy.

NERVE-STRETCHING IN LOCOMOTOR ATAXIA.

The first paper read was by Professor Langenbeck, upon nerve-stretching in this disease, the author relating successful cases where the operation undertaken to give relief to the pains had ameliorated the actual ataxic symptoms, the inference being that stretching of the sciatic nerve initiated changes of a beneficial character in the spinal cord itself. As Sir W. Gull remarked, this introduced a new idea on the nature of ataxy, and Dr. Ogle asked whether the curative effect of nerve-stretching was proved to occur in cases where the lesion of the spinal cord was primary as well as in those cases where it might be considered secondary to peripheral nerve-changes. Professor Eulenberg, of Greifswald, also spoke, and Dr. Brown-Séquard supported the author's views by giving the results of experiments on nerve-stretching which he had found to influence the sensory functions of nerves beyond the region of that actually stretched. Dr. Buzzard, in a paper on certain little-recognized phases of tabes dorsalis, gave a very clear account of the existence of a class of cases in which the classical symptom of ataxy is absent. Such cases, he maintained, are marked by the absence of the knee-phenomenon and by the presence of *crises gastriques*, and sometimes of joint affection; cases in which the gastric symptoms endured for years and predominated over the other characters of tabes—such as the Argyll Robertson phenomenon and lightning-pains—and led to diagnosis of gastric cancer, gout in the stomach, or intestinal obstruction. He also referred to cases where other of the symptoms of tabes predominated, and adopted Perrot's view, that the disease is essentially a chronic inflammation of sensory fibres. Dr. Buzzard lays great stress upon the importance of examining for the patella tendon reflex in all such cases, and it is to be regretted that time did not permit of a discussion upon his paper.

SYPHILIS AS A CAUSE OF LOCOMOTOR ATAXY.

A paper by Professor Erb, of Leipsic, on the "Rôle of Syphilis as a Cause of Locomotor Ataxy," gave rise to considerable debate; and certainly the author laid himself open to the criticism of proving too much, for whilst he found evidence of previous infection in eighty-eight per cent., there were no secondary symptoms in twenty-nine per cent., and he used this as an argument in favor of the unicist view of syphilis. By comparing these statistics with those of other male adults not the subjects of tabes, he found that only twenty-three per cent. of these had been infected at all, and but twelve per cent. had secondary syphilis. The conclusion arrived at was that "tabes in ninety per cent. of all cases is occasioned by syphilis as one of its etiological factors," and it may be pointed out that this is in agreement with the previous statements of M. Fournier and Dr. Gowers on the subject. Dr. Althaus, of London, in the debate said that he had obtained a history of primary syphilis also in ninety per cent. of his cases of ataxy, but of secondary syphilis in forty per cent., and he contrasted these results with a like inquiry into the antecedents of cases of other nervous diseases taken consecutively. But, as Dr. Gairdner remarked, it was a matter of insuperable

difficulty to arrive at a true history of antecedent syphilis (especially where there were no secondary symptoms) in any large number of cases, and he could not accept the conclusions of Professor Erb and Dr. Althaus on this ground alone. An exception might certainly be taken to one of the cases cited by the author, where the search for syphilitic infection (the case was a remarkable one of ataxy in a girl nine years old) resulted in the discovery that the patient's maternal grandfather had been the subject of it!

Opposition to the view of Erb was also directed from the pathological side, M. Lancereaux, of Paris, maintaining that the lesions of locomotor ataxy do not present the characters of syphilitic sclerosis and syphilitic lesions in other organs; and his conclusion was that syphilis and ataxy were coincident, not correlated, believing the reason of the predominance shown by Professor Erb to lie in the fact that ataxy occurs in individuals addicted to sexual excesses. Dr. Banks, of Dublin, thought there was a positive etiological connection between syphilis and tabes; and Dr. Lambred, of Constantinople, and Professor Rosenstein, of Leyden, also spoke on the matter. Sir W. Gull, in closing the debate, pointed out that the syphilitic poison produced indirect effects, inducing degeneration of tissues. The debate has not, therefore, led to definite results; but, taken in connection with the supposed curative effects of nerve-stretching in this same disease, it seems still to leave the question more open than Professor Erb would wish us to believe. A paper by Professor Ball and Dr. Thebierge, of Paris, was contributed to show the dependence of perforating ulcer of the foot upon locomotor ataxy, and in demonstrating its probable connection with trophical disturbance, the authors were in harmony with the views of Mr. Savory and Mr. Butlin in their valuable contribution to the Royal Medical and Chirurgical Society a year or two ago.

### LOCALIZATION OF CEREBRAL AND SPINAL DISEASES.

Dr. Brown-Séquard had undertaken to address the section upon the subject of "Localization of Disease in the Brain and Spinal Cord," from a pathognomonic and diagnostic point of view; and the abstract of his communication offered a very exhaustive field for his remarks. He contented himself, however, with giving a brief oral disquisition, his main contention being that groups of symptoms rather than isolated manifestations must be taken into account in the attempt to correctly localize disease in the brain or cord; and that the effects of a lesion in the centre were produced at a distance, and were irrespective of the direct paths of transmission of nervous impulses—which he illustrated by the fact that a puncture of the medulla will produce degeneration in the sciatic nerve, and a lesion of the sciatic nerve induce changes in the motor centres of the brain. He spoke of a dynamic influence as operating thus on parts at "a distance," and said that the anterior pyramids might be cut without paralysis ensuing, and then their cut ends (central or peripheral) when irritated produced movements on the same side as the lesion, *i.e.*, in parts where the pyramidal fibres do not go. M. Charcot, on the other hand, contended that the facts of clinical and pathological observation were indubitable, and could not be harmonized with the experimental evidence adduced by Dr. Brown-Séquard, who, however, asserted that he believed that certain elements were endowed with distinct functions.

Although it would have been obviously impossible for Dr. Brown-Séquard to have traversed all the lines laid down in the abstract of his paper, his communication suffered somewhat in being as condensed as it was, and the precise points of difference between him and the school represented by Charcot were not clearly brought out. The section had the opportunity, however, of hearing the views of that school enunciated by Dr. Hughlings-Jackson, who indeed is entitled to be considered the pioneer in localization theory. His paper was upon the subject which led to his suggestion of the existence of specialized motor centres, viz., epileptiform convulsions from cerebral disease, and was a masterly review of the whole subject. Dr. Jackson dealt with the following points: (1) Starting-points; (2) ranges; (3) march of spasm; (4) suddenness of onset, rapidity of spreading, and direction of seizures; (5) post-paroxysmal condition (paralysis); (6) post-epileptiform aphasia; (7) affection of consciousness; (8) locality of lesion (anatomical diagnosis); (9) physiology of lesion; (10) pathology of brain; and (11) treatment; and his paper was followed by a debate shared in by Dr. Brown-Séquard, Dr. Sturge, Dr. H. Weber (who cited instances of left epileptiform seizures, followed by weakness on the left side and aphasia) and Prof. Baumber of Strasburg, who suggested the term dysphasia to include the various forms of speech-defect following upon the attacks. Dr. Jackson in replying said, that with reference to aphasia and left-sided convulsions, he had always maintained the existence of two conditions in every case of aphasia, and did not believe in any special speech-centre.

### ADDISON'S DISEASE.

The subject of Addison's disease was opened in a paper by Dr. Greenhow, which comprised the relation of a recent case, and a general summary of known clinical and pathological facts concerning this remarkable affection. He pointed out that research must be specially directed to changes in the abdominal sympathetic and the pneumogastric nerve—a case, recorded by Dr. Paget, of lymphadenoma, in which these structures were involved and the suprarenal capsules unaffected, where a deepening pigmentation of the skin was observed during life, giving support to this view.

In the debate which ensued, Dr. Semmola, of Naples, said that at the Brussels Congress he had related a case, diagnosed as Addison's disease, where improvement followed upon electrical treatment, but death occurred some months later, after an attack of acute dyspepsia. No opportunity was given, however, of confirming the diagnosis in this case, which Dr. Semmola had quoted in support of the view he held, that the suprarenal capsules need not necessarily be the seat of disease; and he exhibited a drawing, showing morbid changes in the spinal cord and cœliac ganglia, which he held to be the essential lesions of Addison's disease. A like position was maintained by Dr. Guéneau de Mussy, who had met with a certain number of cases of bronzed skin, without suprarenal disease, but with affection of the abdominal sympathetics, and he adduced in support of this the cutaneous pigmentation of pregnancy, and the occurrence of pigment-moles on the forehead in cases of abdominal tuberculosis, a phenomenon to which he attaches so great significance as to regard it as almost pathognomonic. Dr.

Zucker, of Berlin, spoke of the changes in the urine, and Dr. Gairdner, of Glasgow, of the association of leucoderma with Addison's disease, instancing a noteworthy case which had come under his notice. Sir W. Gull, remarking that he had seen Addison's earliest cases, did well to remind the members of the importance of the asthenia of Addison's disease, and of not laying too much stress upon the pigmentation. He believed the suprarenal capsules were nervous organs, in structure most resembling the pituitary body, so singularly cared for in its special fossa at the base of the skull, the function of which is just as much unknown. He expressed a doubt as to the prognosis being universally unfavorable, and thought that we should have to study those cases which do not die. Dr. Greenhow, in his reply, maintained that Addison's disease commenced in the suprarenal capsules, and that the association of leucoderma was a coincidence, but not a very rare one, with the cutaneous pigmentation.

BRIGHT'S DISEASE.

Several communications were read upon the subject of Bright's disease. Dr. Rosenstein, of Leyden, in his paper, separated, first of all, such conditions of the kidney as are non-inflammatory as being independent affections; and he then discriminated between acute and chronic Bright's disease, anatomically and clinically. The acute form, characterized by emigration of colorless blood-corpuscles, epithelial, and later, interstitial changes, passes very rarely into the chronic form. The chronic form is a diffuse inflammation of all the tissue-elements of the kidney—represented by the "large white," the variegated, "smooth contracted," and the "granular white" kidney; the red granular kidney starting from endarteritic changes in the renal vessels, and to this form the senile contracted kidney is closely allied. Clinical observations can only recognize whether the organ is enlarged or contracted, and it is unable to distinguish between "parenchymatous" and "interstitial" forms. This is a clear statement of the results ensuing upon modern histological research; and had the paper been read in Section III., it would have attracted more attention. But unfortunately, as above said, no discussion ensued in this section upon the subject. Dr. George Johnson contributed a clinical observation on the evidence of white blood-cell casts as indicative of glomerulo-nephritis; and Dr. Grainger Stewart read a paper upon the condition of the urine in Bright's disease, and the clinical value of its examination. Dr. Semmola, of Naples, argued that Bright's disease might be induced by alterations in the albumen of the blood. This paper was followed by a brief communication from Prof. Stolaris, of Amsterdam, who related some experiments showing that the subcutaneous injection of albumen could produce glomerulo-nephritis, an experimental support of Dr. Semmola's view. Dr. Mahomed raised a very important subject, which he entitled "Chronic Bright's Disease without Albuminuria," including an analysis of cases of high arterial pressure producing the cardio-vascular changes characteristic of chronic Bright's disease, with red granular kidneys, but without albuminuria, the number of cases being sixty-one, twenty-one of which were fatal. Dr. Mahomed stated that his views would appear at length in the forthcoming volume of "Guy's Hospital Reports," but it would certainly have been well for the question to have been thoroughly debated in the section, bearing as it does in so important a manner upon clinical observation.

LITHIASIS AND ITS ALLIANCES.

The subject of gout was dealt with under two different aspects, viz., in a paper by Dr. Garrod, upon "Eczema and Albuminuria in Connection with Gout," and in one by Mr. Jonathan Hutchinson, on "Rheumatism, Gout, and Rheumatic Gout." Dr. Garrod's observations included a very large number of cases of undoubted gout, having selected cases in which there had been, at one time or another, arthritic manifestations, and he conclusively proved the very great frequency with which eczema occurred in such subjects, and also renal disease, pointing out the characters of the renal affections. Mr. Hutchinson's paper embraced a wider field: he defined rheumatism as, in the main, a liability to joint-disease, brought about by exposure to cold, and not through reflex nervous influences—a catarrhal arthritis; and gout as, in the main, a liability to joint-disease, brought about by certain articles of food, by defects of assimilation and of excretions—a humoral arthritis. He thus establishes a certain link between the two, viz., the liability to joint-disease; but he was especially careful to point out that, in either, by hereditary transmission, a "gouty" or "rheumatic" diathesis may be formed. In support of his view of an underlying arthritic tendency or condition, he referred to the remarkable frequency of "rheumatic gout," and of the association of deposits of lithate of soda in joints, with lesions of cartilage and bone, hitherto considered as typically rheumatic, and concluded his lucid exposition of the subject by referring to the existence of certain maladies which "are to be affiliated with gout and rheumatic gout as certain forms of iritis, hemorrhagic retinitis, chronic rheumatoid arthritis, some forms of glaucoma, lumbago, sciatica, and neuralgia, novi digitorum, and possibly hæmophilia."

An interesting debate ensued, in which the speakers mostly aimed at showing that there was nothing in common between gout and rheumatism, but they must have missed the point of Mr. Hutchinson's thesis, for in his reply he claimed them as adherents to his cause. Thus, Dr. Garrod thought that the great aim was to differentiate diseases, and not to merge them into one another; that the gouty condition was perfectly distinct and separable from the rheumatic; that gout was almost unknown in Scotland, where rheumatic arthritis was common; that erosion of articular cartilages occurred as a consequence of uratic deposit in chronic gout; and that, although the children of gouty parents suffered from rheumatic arthritis, it was not because there was an interchange of the diathesis, but simply because they were the offspring of debilitated parents. He also believed that gonorrhœal rheumatism had more analogies with pyæmia than with rheumatism. Dr. W. Roberts said that in Manchester cases of gout in hospital practice came mostly from London, which he attributed to the porter-drinking habits of the London poor; and Dr. Quinlan, of Dublin, said that since the people there had taken to drinking porter instead of whisky, gout had become common, whereas previously it was almost unknown. Dr. Stokin, of Amsterdam, said that true gout was very rare in his city; he had seen only two cases, and those in debilitated women, living in unhealthy conditions. Dr. Maclagan, of London, said that true gout was very rare in Scotland, but acute rheumatism and rheumatic arthritis were common—the latter especi-

ally in weakly girls and women. He believed rheumatism to be due to a miasm, and not to the influence of cold and wet; for those most liable to be influenced by cold and wet, the very young and the aged, did not suffer from rheumatism. Dr. Grant, of Montreal, said that gout was hardly known in Canada, whereas rheumatism, arising from insufficient protection against cold, was common. Dr. Ord thought the arthritic changes were common in association with deposits of urate of soda in joints, and would use arthritis as a term common to both gout and rheumatism. In his view, gonorrhœal rheumatism was more allied to rheumatic arthritis than pyæmia—suppuration was not common in it, and similar articular affection accompanied arthritis, prostatitis, etc., not gonorrhœal.

Dr. Duckworth pointed out that the uratic deposits signified gout, and that the hereditary gout occurred apart from dietetic errors. He considered the extensive arthritic changes sometimes seen in gouty joints were very rare, but admitted that sometimes a case appeared to present a coalescence of gout and rheumatism. There was often, however, great difficulty in getting a reliable history of gout. In his reply Mr. Hutchinson not only showed that he granted the hereditary transmission of gout, and that lithates were deposited in the tissues in the disease, but that gout and rheumatism may mingle and often do mingle in the same subject. Indeed, so far as we understand Mr. Hutchinson's position, it is simply this: that there is a tendency to arthritic disease which may partake of the characters of gout or of rheumatism, alone or conjointly, according to the influences to which the subject may be exposed, and that position was not strictly contested in the debate.

### THE ANALYTICAL STUDY OF AUSCULTATION AND PERCUSSION.

Professor Austin Flint's paper on the "Analytical Study of Auscultation and Percussion," which he read on the last day of the session, was one of a very important character, aiming at the simplification of the terminology of physical pulmonary signs, and basing the description of such signs upon the character of the sounds themselves, and independent of the mechanism by which they are produced. He was followed by Dr. Douglas Powell on the value of Bacelli's sign "Pectoriloquie Aphasie" in the differential diagnosis of fluid effusion into the pleura. Dr. Bacelli maintained that in a case of pleuritic effusion, if the whispered voice be well conducted and pectoriloquous, the fluid may be certainly regarded as serous; but, if ill-conducted or inaudible, the fluid will be found to be purulent. Dr. Powell's own observations led him to the conclusion that the sign in question is not pathognomonic, although of considerable value in association with other signs. Sir W. Gull said that Dr. Bacelli's sign is no new thing, and referred to Dr. Addison's observations upon the same sign in 1846; and his own (Sir W. Gull's) explanation of them on the physical ground of tenseness of the membrane and chest-wall. Prof. Ewald, of Berlin, agreed with Dr. Powell, that Bacelli's sign is not reliable, but that the only certain means of diagnosis is by puncture. Prof. D'Espine, of Geneva, also spoke.

Dr. Mahomed urged that the Congress should take action to draw up a single code of terms, but Dr. C. T. Williams pointed out that the difficulty lay in the differences in the instruments employed, and Dr. Flint in his reply echoed Dr. Mahomed's wish that there should be established a general uniformity of terms. On the proposal of Sir W. Gull a committee was formed, consisting of Professor Ewald, Professor D'Espine, Dr. Douglas Powell, Dr. Austin Flint, and Dr. Mahomed, to report to the next Congress. Dr. C. T. Williams then read a paper on the treatment of Phthisis at High Altitudes, drawing especial attention to the increased expansion of the chest following residence at these sites, and attributable to diminished barometric pressure. Dr. Norman Chevers pointed out the bad influence of hot climates on phthisis. Dr. H. Weber, of London, said that it was not a mere question of chest-expansion, but of purity of air, which at high altitudes, such as Davos, does not promote fermentation. Similar effects were produced at Algiers, Madeira, and other aseptic climates. With hereditary influence strongly marked, cases in the first stage even advance at Davos and Colorado. But everywhere general medical supervision and management are essential. Dr. Wilson Fox said that phthisis was due to impure air, bad food, inheritance, and possibly septic causes. Nearly all high altitudes are curative, even in such hot climates as Bloemfontein. The finest shaped chests are liable to tubercular affection. He asked for information as to how long this cure lasts. If phthisis is to be cured by asepticism, then a six months' residence is sufficient; but if desirable to get changes in shape of chest, a longer time must be spent; and he appealed to those at Davos to keep their patients through the summer as well as winter. Dr. Alan Herbert, of Paris, urged physicians to establish the indications for sending patients to Davos, and also contraindications — especially cardio-vascular disease.

Sir W. Gull, in closing the session, said he did so with great regret. There had been one uniform sentiment governing all—viz., a desire to work *pro bono publico*. He thanked the members for the courtesy shown to himself.

### THE TREATMENT OF SCROFULOUS NECK.

We must bring this brief survey of the work of the section to a close, and must be contented to enumerate a few of the chief remaining subjects which were under discussion. Of these one of the most interesting was raised in a paper by Dr. Clifford Allbutt, upon the treatment of scrofulous neck. He contended for early surgical interference to remove the enlarged glands, and thus anticipate the evils of their suppuration or caseation, and the liability to constitutional infection thereby supervening. M. Jules Guérin recapitulated some views on the etiology of typhoid fever he had previously enunciated before the Paris Academy of Medicine, to prove that the disease originates from "fecal intoxication," but, as Sir W. Gull remarked, he did not sufficiently discriminate between the septicæmic effects and the conditions of the febrile process itself. Dr. W. Roberts drew attention to the presence of bacteria in the bladder, giving rise to fermentation of the urine and vesical irritation, a condition removable in a few days by thirty-grain doses of salicylate of soda twice a day. Papers were read also by Prof. Eulenberg, of Greifswald, on Graphic Representations of Tendon Reflex; Dr. D'Espine, of Geneva, on Clinical Cardiography; Dr. Redard, of Paris, on Local Thermometry; Prof. Lépine, of Lyons, on Biliary Secretions in Morbid States; and Prof. Zucker, of Berlin, on the Phosphor Acids of the Urine.

## SECTION ON PATHOLOGY.

### THE NOMENCLATURE OF TUMORS.

After the delivery of the address by Dr. Wilks, already published, the remainder of the first session was occupied in the delivery and discussion of two papers by Dr. Malherbe (Nantes), both treating of tumors. In connection with these papers arose the question of the international nomenclature of tumors, for although there appeared to be a unanimity of opinion on the nature of the tumors of which Dr. Malherbe spoke, the names by which he called them were objected to by some of those who took part in the discussion. Certainly, one great object for the meeting of pathologists of many nations would be gained if an understanding could be arrived at as to the meaning which should be applied to certain of the more doubtful terms employed in the nomenclature of tumors. At present, not only has each nation its own peculiar nomenclature for certain tumors, but, worse still, each school is apt to use the same term in a different signification, and thus the study of oncology is rendered far more difficult than otherwise it would be.

A similar complaint was made on the following morning (Thursday) in reply to a paper on "Tubercle" by Dr. Grancher (Paris); for Dr. Wilson Fox pointed out that since so many doubts had been of late expressed concerning the nature of tubercle, cases which were formerly called cases of tuberculosis, and which probably are still tuberculosis, are now often entered in the registrar's returns as cases of pneumonia or broncho-pneumonia, or the like, by which means the present time will furnish far fewer cases of death from tubercle of the lungs than past times. His suggestion that the term phthisis should be employed for all such cases seems to meet the difficulty. The discussion on Dr. Grancher's paper gradually lapsed into a discussion on the nature of giant cells; and even here the difficulty of adhering strictly to the lines of the debate was clearly shown. For while Mr. Treves spoke only of the giant cells of tubercle, and maintained that they are only masses of coagulated lymph, Dr. Creighton, who followed him, spoke of the giant cells which are formed in the normal placenta, and Prof. Virchow of giant cells wherever they occur.

### MICRO-ORGANISMS AND THEIR RELATION TO DISEASE.

Two whole days devoted to the subject of "Micro-organisms and their Relation to Disease" may seem too large a portion out of a week: yet when one thinks of the importance of the subject, and of the interest it is creating in every region of the scientific world, the time was not at all too long. On Friday, the duty of introducing the debate was intrusted to Professor Lister. He contented himself with delivering a clinical lecture on sympathetic inflammation and counter-irritation. Professor Bastian followed with a very able speech, perhaps a little too pointedly addressed to, or rather against, Mr. Lister, but clear to the point. His contention that micro-organisms may arise by changes in the protoplasm of degenerating or decaying tissues (heterogenesis) was supported by an account of various experiments, and by strong, though possibly not invincible, arguments. By this time the room was very full and very hot, and the debate, which had been waxing warm, speedily assumed a fiery hue; for the next to follow was Professor Pasteur, who, looking very ill, and obliged to sit at the speaker's bar, yet threw a marvellous energy into his speech. Unable to understand our language, he had, he said, begged Mr. Lister to tell him in two words the purport of Professor Bastian's speech. It was, he understood, that micro-organisms may be formed by heterogenesis of the natural tissues. "Mais, mon Dieu," said the 'great father,' banging his fist upon the table, "ce n'est pas possible." "Never, never," he added, pointing his outstretched finger at the unfortunate Dr. Bastian, as if to denounce him, "are these organisms developed, unless from previously existing germs or organisms."

Professor Virchow showed how essential it is that the relation of the various micro-organisms to one another should be discovered. He believed it possible, by "domestication," to change the nature of certain of these organisms, and related recent experiments bearing on this matter. On the following day (Saturday) the subject was resumed from a slightly different aspect by Professor Fokker (Groningen) and Professor Klebs (Prague), the former contending that the forces of micro-organism, and even its capabilities for good or evil, depend upon the conditions in which it exists; the latter reviewing shortly the various organisms and diseases which appear to be associated with one another. Professors Hueter, Pasteur, and Béchamp, and Mr. Watson Cheyne, conducted the discussion to its close. In connection with this subject, the admirable micro-photographs exhibited by the oxy-hydrogen microscope by Dr. Koch must not be forgotten, or his cultivation methods for micro-organisms, demonstrated to a chosen few at King's College. The latter were especially interesting as displaying the advantages of cultivation in solids. In a single potato Dr. Koch was able to show several beds of micro-organisms, each bed containing a separate and apparently pure organism. By thus employing a solid medium, the mingling of organisms, so difficult to prevent in fluids, is rendered almost impossible.

### RENAL DISEASES.

The discussion on renal disease (Monday) was scarcely so interesting as those of the preceding days. Sir William Gull read a short paper, which, however, was rendered long by continual repetition and interpolation. The views of Drs. Gull and Sutton are well known, and those of Dr. Lancereaux (Paris), who read a paper on the same subject, were somewhat in a similar strain; but they failed to draw Dr. George Johnson into the discussion, who contented himself with acknowledging that he had formerly been mistaken in believing that the thickening of the intima of the arterioles was a thickening of all the elastic structures of the inner coat. The second part of this discussion dealt with the histology of the various forms of Bright's disease, but this too failed to elicit any very new or striking facts.

### THE SENSORY AND MOTOR TRACTS OF THE CEREBRAL NERVOUS APPARATUS.

On the last morning the section was thinly attended, partly because none of the great "stars" of the Congress were advertised to attend, partly because the subjects were of such a kind that discussion was practically in the hands of a very few persons; yet some of the work was eminently interesting; for example, the charmingly lucid demonstration by Professor Pierret (Lyons), of the normal relations of the sensory and motor tracts of the cerebral nervous apparatus, and of the manner in which the sensory tract is affected by systematic inflammation. Professor Pierret had already, some

days previously, exhibited a number of excellent sections of the medulla and pons, in which the course of certain of the nerves could easily be traced to their origin in the ganglia. Dr. Dreschfeld also gave an account of what is believed at present to be a unique case of primary lateral sclerosis, actually illustrating in fact what has been regarded by nerve-pathologists as probable in theory. By midday the work of the section was completed.

PATHOLOGICAL SPECIMENS AND DRAWINGS.

The description of a large portion of the contents of the museum properly falls to the lot of this section, for it was largely composed of pathological specimens and drawings. Amongst other things well worthy of note was a life-size wax model of a woman suffering from affection of the articulations in connection with tabes dorsalis, lent by Professor Charcot, and the bones removed from the same patient after death. The model was, indeed, the most attractive object of the museum, for it was admirably executed. Very interesting, too, was a skeleton from the Brighton Hospital of a man who had apparently suffered from rickets and mollities ossium. The various metropolitan hospital museums lent their choicest specimens: wax models of skin disease from Guy's; ostitis deformans from St. Bartholomew's; Sir Astley Cooper's case of ligature of the abdominal aorta, and specimens of skilful mounting and preparation by Mr. Stewart, from St. Thomas's; madura foot from University and St. Bartholomew's. The military and naval hospitals contributed gun-shot wounds of bones and joints; and the Dublin College of Surgeons entrusted to Mr. Abraham's safe-keeping a classical series of cases of Colles' fracture, and a very rare, if not unique, specimen of fracture of the spine of the tibia. In addition, there were numerous tumors in bottles, and casts of tumors, and drawings of tumors; and, lest vegetable pathology should be omitted, Mr. Stephen Paget had furnished a collection of tumors from various trees, the collection on which his father's address to the British Medical Association last year was founded.

## SECTION ON STATE MEDICINE.

FIFTH DAY—MONDAY, AUGUST 8TH.

JOHN SIMON, ESQ., C.B., D.C.L., LL.D., F.R.S., PRESIDENT, IN THE CHAIR.

A paper was read by ERNEST HART, on the

INFLUENCE OF MILK IN SPREADING ZYMOTIC DISEASE.

The speaker gave an abstract of seventy-one recent epidemics due to infected milk. He then said:

The three diseases which have as yet been recognized as capable of being spread by milk, are typhoid fever, scarlatina, and diphtheria. There is nothing in the analogy of epidemics to limit the list permanently to these; and already there are indications of other cognate diseases being spread by the same agency. The number of epidemics of typhoid fever recorded in the abstract as due to milk is 50, of scarlatina 14, and of diphtheria 7. The total number of cases traced to the drinking of infected milk occurring during the epidemics may be reckoned in round numbers as 3,500 of typhoid fever, 800 of scarlatina, and 500 of diphtheria. As regards typhoid fever, the most common way in which the poison has been observed in these epidemics to reach the milk is by the soakage of the specific matter of typhoid excrements into the well-water used for washing the milk-cans and for other dairy purposes, and often, it is to be feared, for the dilution of the milk itself,—for which, in official reports, "washing the milk-cans" has become a convenient euphemism, advisedly employed to avoid raising unpleasant questions.

In twenty-two of the fifty epidemics of typhoid fever recorded, this is distinctly stated by the reporters to be the case, and in other cases it was more or less probable.

When a dairy is unwholesomely or carelessly kept, there is obviously a great variety of ways in which the poison may reach the milk. Numerous instances of this kind were given.

THE VALUE OF QUARANTINE.

The preliminary arrangements and the address occupied so much time, that the commencement of the reading of the papers was postponed till Thursday morning. The first question then brought under the consideration of the section, was the mode of propagation of yellow fever and cholera, and the means best adapted to prevent their diffusion either from one country to another, or within any country. Dr. Billings communicated the results of the experience of late years in the United States. As regards yellow fever, he considered it as a specific disease, capable of communication from person to person, and through the medium of clothing, etc. Inspector-General Lawson, on the contrary, in stating the results of his experience on the West Coast of Africa and in the West Indies, attributed its origin to local causes, and did not believe it capable of transmission by means of clothes or other porous materials. Both views found supporters in the discussion which followed. Dr. Billings was strongly in favor of quarantine, but did not include under that term detention of vessels, on board of which cases had occurred, for a longer period than might be necessary for the thorough cleansing of the vessel and the disinfecting of all articles of clothing; and he suggested the necessity for an international exchange of information when any outbreak of fever or cholera occurred. Attention was called by Dr. Fauvel, of Paris, to the very different climatic conditions of the various countries in which yellow fever occurs, and the consequent necessity for leaving to each country the arrangement of such details as it may consider necessary for the limitation of the disease. A paper was afterward read in abstract by Dr. Christie, on the measures by which to prevent the diffusion of dengue. The author gave an account of several epidemics of this disease, and believed the only mode of prevention to consist in improved sanitary conditions.

PREVENTION OF DIFFUSION OF CONTAGIOUS DISEASES.

The meeting of Friday morning was occupied with the question of the best means of preventing the diffusion of syphilis. Several abstracts of papers on the subject were read, which led to a long, warm, but not very profitable discussion of the principles and operations of the Contagious Diseases Acts. This was going on when the hour for adjournment was reached, and the discussion was closed still unfinished. The afternoon sitting was devoted to the question of home contagia, as manifested by enteric fever, scarlet fever, measles, whooping-cough, diphtheria, etc. Professor de Chaumont read an abstract of an excellent paper on the principles to be observed in attempting to prevent the diffusion of disease, and was followed by an account by Dr. Gil-

bert of an outbreak of typhoid fever in Havre, apparently caused by defective drainage and sewerage arrangements; one by Dr. Stopford Taylor on the importation of infectious diseases into Liverpool, their diffusion, and means of prevention; and an abstract of a paper by Dr. Page on the prevention of the spread of scarlet fever, especially with reference to the period of incubation, the time during which the power of infection probably continues, and when, consequently, isolation ought to be enforced, and the measures of disinfection and purification of persons, houses, and clothing requisite after the occurrence of cases of the disease. The discussion on these important points was postponed, owing to the want of time after the abstracts were read.

THE INFLUENCE OF FOOD ON THE SPREAD OF DISEASE.

On Saturday, the subject under consideration was the influence of various articles of food—not including water—in spreading parasitic, zymotic, tubercular, and other diseases. The probable transmission of tubercular disease to man from animals, through the medium of milk and meat, was brought forward by Dr. Creighton, of Cambridge; the occurrence of an acute specific disease from eating pork infected with a species of bacillus, by Drs. Ballard and Klein; and abstracts on the diffusion of diseases by various articles of food were read by Mr. Hart, Dr. Vacher, and Dr. Hogg, while Dr. Carpenter briefly brought to notice the freedom from disease-producing qualities of food, either animal or vegetable, raised from sewage-irrigated fields. These important subjects gave rise to very little discussion—a result, we fear, of the various more interesting, though perhaps less important, social engagements which had been made for the purpose of giving pleasure to our foreign and country friends.

THE INTERNATIONAL LICENSE TO PRACTICE MEDICINE.

The meeting on Monday was opened with a paper by Dr. Acland, on "International Conditions of Admissibility to Practice," which gave rise to an animated discussion. He submitted that there are conditions under which one civilized country should give to holders of foreign diplomas privileges equal to those conferred on possessors of its own; that these conditions should not necessarily involve a re-examination: that they need not be the same as between a mother-country and her colonies, and that the granting of such privileges by a country need not imply reciprocity on the part of others. There appeared to be nearly a general acceptance of Dr. Acland's proposition that admission to practice should be governed by satisfactory evidence of qualification, professional and moral, altogether independent of any question of reciprocity. Dr. Acland's paper was followed by an abstract of one by Dr. Rabagliati, on "The Precautions to be Taken in Medical Nomenclature and Classification to Guard Against False Statistical Conclusions," but from the very brief period allowed for the reading, and the extremely condensed form of the abstract, it was difficult to ascertain the full bearing of the paper. It elicited some remarks on the necessity for publishing tables of diseases *in extenso*, instead of giving merely classified abstracts.

PREVENTION OF HYDROPHOBIA.

Dr. H. Van Capelle gave an interesting account of the measures adopted in Holland to prevent the diffusion of hydrophobia, with their results, illustrated by maps showing the distribution of fatal cases of the disease among the population of Holland in each year from 1875 to 1880. Dr. Colam, who was fleet-surgeon with the late Arctic Expedition, read a paper on the "Dog-disease or Canine Madness of the Arctic Regions, Viewed in Connection with Hydrophobia, Together with the Measures Used and Suggested for its Extinction." In the discussion which followed, much importance was attached to stamping out the disease by the destruction of all dogs affected as soon as its existence is clearly ascertained. Mr. Dolan, who gave details of the prevalence of rabies in England, and its progressive increase during the last few years, urged the necessity for an efficient Dog Act to enable this formidable disease to be brought under control, a suggestion which appeared to meet with the support of the section.

PREVENTING HOME CONTAGIA.

On Tuesday, after a paper by Dr. M'Cormack, of Belfast, on "Limiting the Force of Contagion and Infection by Holding the Breath whilst in Immediate Contiguity with the Sick," the discussion on home contagia, which had been postponed from Friday, was taken up. Dr. Bloxall gave an account of an outbreak of cholera in the fleet at Malta, which afforded strong evidence of local origin, and both he and Dr. de Chaumont expressed decided opinions of the inadequacy of quarantine to ward off the disease in the absence of proper hygienic measures. As regards the spread of enteric fever, scarlet fever, measles, whooping-cough, and diphtheria, and especially scarlet fever, much importance was attached by various speakers to the registration, or, as Mr. Simon more correctly termed it, the notification of cases of infectious diseases; the establishment of free hospitals for their treatment; the detention of the cases for a sufficient length of time in these hospitals; and the judicious use of disinfectants. Of the latter, heat appeared to be the most relied on for the disinfection of clothing, bedding, and such articles, while fresh air, hot water, and sulphur-fumigation were deemed most efficacious for buildings. The discussion was followed by an abstract of a paper by Dr. Carpenter, on "Sewage Irrigation," which, in the absence of the author, gave rise to very few remarks. At the conclusion of this paper, Dr. Varrintrapp, after a well-merited eulogium on the valuable services which had been rendered by Mr. Simon to sanitary science, not in England only, but over the whole world, proposed a vote of thanks to him for the manner in which he had discharged his duties as President of the Section, and this, with a similar vote to the Secretaries for their valuable and important services, having been unanimously accorded, the proceedings of the department of state medicine were brought to a close.

## SECTION ON DERMATOLOGY.

FIRST DAY—WEDNESDAY, AUGUST 3D, 1881.

ERASMUS WILSON, ESQ., F.R.S., PRESIDENT, IN THE CHAIR.

PRESIDENT'S ADDRESS.

After welcoming the members, and referring to the relative importance of constitutional as compared with the local treatment of cutaneous affections, THE CHAIRMAN remarked:

"For therapeutical purposes all diseases of the skin

might be assembled, if we except syphilis and diseases proceeding from local causes, under three heads, namely: diseases depending on disorder of digestion and assimilation; diseases depending on disorder of innervation; and diseases of nutrition. As an example of the first kind, we might take eczema, with its multitudinous manifestations. As an example of the second we should have pruritus and prurigo; and, as examples of the third, papilloma and fibrosis. But we cannot fail to recognize the fact, that, practically, there is a greater or less blending of the whole. The pruritus of eczema belongs to disordered innervation; and aberration of nutrition may be accompanied with symptoms which appertain to both the others. Thus, in the lepra of Willan, the psoriasis of modern schools, we have a disease which is due to altered nutrition of the skin from defective organization of that structure. But as the nerve-power or life-power of the skin is insufficient to restrain abnormal function, so capillary congestion constitutes a part of the disease, and the hypertrophous growth of papillæ and excessive production of morbid epidermis must be regarded as a passive nutritive change or passive growth. In ichthyosis, with a starved condition of the skin as far as nutrition is concerned, we have an excessive papillary growth, and excessive accumulation in the shape of altered epidermis. But still more interesting illustrations of abnormal nutrition are evinced by excess or defect of pigment; by the substitution of a lowly for a more highly organized tissue, as in fibrosis, and by the exuberant proliferation of cell-tissue of low organization, which is met with in the instances of tines, of favus, and of epithelioma. If I were called upon to summarize the diseases of the skin such as they exist most commonly in this country, I should begin with eczema, as occurring at all ages and in every condition of life; tinea might follow next as a disorder of childhood; then the acne of youth; and next the so-called acne rosacea of the adult, which latter is actually a form of eczema. The lepra of Willan is not very common, neither is scrofula in its cutaneous forms. Looking to the cause of these diseases, we find mal-assimilation and nerve-irritability, aberration of nutrition and defective nutrition. And, therapeutically, our most reliable remedies are mild purgatives with tonics in the diseases of dyspeptic origin, nutritive tonics, and especially arsenic as a nutritive tonic and in that sense a direct nerve-tonic. What I have now said is intended to open up to the minds of my hearers a picture of the broad field in which we all mutually labor, to point out that many portions of that field admit of independent exploration, and to show that, starting from the line of our existing knowledge, there yet remains very much to investigate—singly, for the perfection of the parts, and collectively for the perfection of the whole. This is the field of dermatological culture and research; and with this brief introduction, I now call you to the work of our section."

---

Fracture of Both Femurs in a Child.—Dr. J. F. Jenkins, of Tecumseh, Mich., reports the case of a child, two years old, both of whose femurs were fractured transversely at the middle third, as the result of a fall from a window. Hamilton's double splint was applied, and the result was perfect. There was no difficulty in keeping the parts in position, nor did the child, who was strong and active for his age, rebel against the necessary confinement.

# Medical Items and News.

Contagious Diseases — Weekly Statement. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending August 20, 1881.

| Week Ending | Typhus Fever. | Typhoid Fever. | Scarlet Fever. | Cerebro spinal Meningitis. | Measles. | Diphtheria. | Small-pox. | Yellow Fever. |
|---|---|---|---|---|---|---|---|---|
| Aug. 13, 1881. | 12 | 18 | 95 | 10 | 30 | 99 | 18 | 0 |
| Aug. 20, 1881. | 4 | 20 | 57 | 6 | 24 | 62 | 24 | 0 |

Typhoid Fever and Sewerage.—Dr. A. D. Lake, of Perrysville, N. Y., sends us a report of thirteen cases of typhoid fever occurring in the Thomas Asylum for Orphan Indian Children, and caused by defective sewerage. The sewerage being perfected, the epidemic ceased. Although this is an old story, it needs occasional repetition.

Symptomatic Epilepsy in Uterine Retroversion.—Dr. J. S. Carreau, of this city, relates a case of epilepsy caused by retroversion. The diagnosis of the latter was easily made, and the rectification of the malposition was attended with disappearance of the epilepsy.

Typhoid Eruption Only on Head, Arms, and Breast.—Dr. Blair D. Taylor, Assistant Surgeon U.S.A., communicates an interesting case of death from a severe attack of typhoid fever, in which the eruption, abundant in degree, occurred only on the head, arms, and breast. The duration of the disease was nine days. There was an irregularity in the temperature, that in the morning exceeding that of the evening. The head-symptoms were slight; the intestinal lesions were rapidly developed. At the autopsy the ileum was found intensely congested on its peritoneal surface, presenting livid prominences corresponding with the ulcerated spots inside. Peyer's patches were found very much swollen, indurated, and ulcerated. All the solitary glands were swollen, and the majority ulcerated.

How to Extract the Ball.—Dr. G. P. Hachenberg, of Austin, Texas, writes: "It strikes me, to ascertain positively the location of the ball in the President's body, should it be deeply imbedded, with the least local and constitutional disturbance, is to transfix the point of prominence, where it is supposed to be, with a long acupuncturing needle. Withdraw the needle through a canula, letting that remain to aid in future explorations. For this purpose an attenuated probe, or one with an ivory end, to receive traces from the lead, can be used. Another method to ascertain the presence of the ball is to run a style through the canula, with a screw or scraper at the end; with an instrument of this kind, its location can be demonstrated in different ways. After its position is fixed without a doubt, transfix it firmly with a screw style, which is to serve as a director for its extirpation, and to favor its extraction through the smallest possible opening. Where a counter-opening is indicated, this method of extraction can usually be done with no greater risk than many forms of dissection."

# Original Communications.

## THE CHANGES WHICH SURGERY HAS UNDERGONE DURING THE LAST TEN YEARS.

ADDRESS DELIVERED AT THE FOURTH GENERAL MEETING OF THE LONDON SESSION OF THE INTERNATIONAL MEDICAL CONGRESS, AUGUST 8, 1881.

BY PROFESSOR VOLKMANN,

HALLE, SAXONY.

GENTLEMEN: It is with hesitation, and only in accordance with the wish of my London friends, that I have undertaken to speak before such a distinguished assembly, and to make an attempt to sketch a hasty picture of the changes which surgery has experienced in the last fifteen or even ten years. And I trust that in this attempt I may rely on your special indulgence; for great and unparalleled in the history of medical science have been those changes. Problems thousands of years old have been solved, or are at any rate approaching a definite solution; the desires of our fathers have been fulfilled beyond their hope of expectation. But all our practice and theories have been also fundamentally altered. The position of our science, the position that we ourselves occupy toward invalids, have become entirely different. And this revolution, in the midst of which we still stand, although the first wave has exhausted itself, has been called forth by the *one* incontestable fact, that all those countless and incalculable disturbances by which the wounds, and hence also the life of those operated on or wounded, are threatened, are only the consequences of particular processes of decomposition of the animal fluids, brought about by the intrusion of lower organisms.

For, with the recognition of the manner of their origin, and with the knowledge of their nature, we have also gained the power of preventing these disturbances. Conscious of our aim, we are able so to act as to paralyze the evil influences of these microorganisms. The fate of countless invalids is from henceforth placed in our hands. In the place of blind chance, in the place of fortune or misfortune, which formerly played so great a part in the work of the practical surgeon, there now appear, in quite a different degree, knowledge and ignorance, capability and inability, care and carelessness. But a short time ago the surgeon, when he had, according to the rules of his art, made a wound, was like the husbandman who, when he has sown his field, patiently awaits the harvest, and accepts it as it may turn out, powerlessly exposed to the elements which may bring him rain and sunshine, storm and hail. Now he is the manufacturer from whom we expect good wares. By rescuing from the domain of chance the results of our labors, as far as they depend on operations and the treatment of wounds—and this will always remain the chief and especial work of surgery—the antiseptic method has elevated surgery to the rank of the least experimental science.

But never has a discovery been made in surgery which has even approached this in its benefits to humanity in general. Many thousands of human beings have in the short space of time that has elapsed since then, preserved life and limbs, and been spared pain and a long confinement to a sick-bed; and millions will yet share in these benefits, for the principles of the antiseptic treatment of wounds will *never* again be abandoned so long as the whole of our knowledge is not lost, no matter how our art or the points of attack may change. Perhaps we may some day succeed in treating injured limbs simply in heated or filtered air, or may learn to strengthen the living power of resistance of the tissues and organs so that they can of themselves resist the action of those invisible enemies. The protection afforded by vaccination makes it appear possible that in this, also, new paths are opening out to us.

England may be proud that it was one of her sons whose name is inseparably connected with this the greatest advance that surgery has ever made. Without envy, other nations may yield her the crown; for the long and silent labor which made the ripening of the seed possible, which we now reap so quickly and fully, was quite international; and especially France and Germany took part in it in an equal degree. Nor did any one more fully recognize the importance of those who worked before him than Mr. Joseph Lister.

Otherwise it has happened with the discovery of the antiseptic method, as with so many great discoveries; years, sometimes centuries, prepare them; they are in the air, as it were, until one day, to the surprise of mankind, they suddenly seem to fall down from heaven. Nothing is more instructive than to reflect the light of our present knowledge, or the endeavors of past times, to see how, since the beginning of this century, the most heterogeneous opinions have been held concerning the treatment of wounds: how methods apparently the most opposite have been employed, in all of which we may, however, now recognize a certain value. How wounds were treated with ice, with the cautery iron, with alcohol; how they were ventilated, hermetically closed; how the subcutaneous modes of operation were resorted to without deciding the question why the air coming into contact with the injured tissues of the body in one series of cases caused such deleterious results, in others appeared perfectly harmless; how, seeking without any firm leading principle, experimenting and often abandoning one's self to the rudest empiricism, yet the goal was approached nearer and nearer—so near that we might suppose it was almost possible even then to grasp the truth, and that every one ought to recognize it, and then, when daylight is approaching, and the chief problem has been solved, that then the complete failure of our art is shown by the adoption of the open treatment of wounds.

I consider the direction given by Stromeyer and Pirogoff—especially for gunshot-wounds, and in their time perfectly justified—never to probe a fresh wound, is here carried out to actual nihilism, and to our shame proofs are given that with passive looking on, and the renunciation of quick healing by first intention, with good cicatrizing the results were, on an average, better than in all active methods of treatment practised up to that time. Gentlemen, I wish not to be misunderstood. I do not mean that open treatment of wounds which is at this day employed in the most efficacious manner, in combination with strictly antiseptic measures, where the locality or serious disturbances already caused in the wound do not permit of the usual appliances, or when, finally, after an operation performed with all the means of protection which modern surgery affords us, we may so safely count upon a healing by first intention that further measures seem unnecessary. I will also point out that the German surgeon

who first employed the open treatment of wounds, and gave it its name, and achieved excellent results with it—Burow—introduced in connection with it a remedy which we now know as one of the strongest antiseptics: *i.e.*, the argilla acetica. But I speak of that open treatment of wounds which, rejecting all the attainments of modern surgery, was so emphatically lauded as a special method to be preferred to all other modes of treatment.

Gentlemen, in speaking of the open treatment of wounds, I have touched on the opposition which the new doctrine at first met with on so many sides. You all know well how violent this was. Even in science great changes cannot be brought about without injury to numerous individual interests; but I insist that nowadays no serious opposition exists; that there is no surgeon who would dare, at the operating-table, or in the treatment of the wounded, quite to renounce antiseptic methods; who calmly and with a good conscience would tread the paths in which, fifteen years ago, we all followed like sheep. Even the most obstinate have had to give way to the great principles of the new era, and often in a much higher degree than they acknowledge to themselves or others—the necessity not only of the disinfection of hands, sponges, instruments, and bandages, but also the necessity of a primary disinfection of fresh wounds, is, I believe, universally acknowledged.

In this respect, then, the time that we have lived through stands alone. In a period of a few years a new revolutionizing doctrine, and a new difficult method of treatment, which increases to the utmost the responsibility of the surgeon treating the case, has celebrated its triumph through the whole of the educated world.

I hope you will think it natural if I, in the attempt to sketch the most essential points by which modern surgery differs from that of past times, place in the first rank the immense diminution of mortality after serious operations and severe injuries. It seems natural to prove the advances made in this respect, by comparing the mortality under the old surgery with that of the present day. But in spite of all trouble and labor, the only result of such attempts is the conviction that our present results are incomparably better. How great used to be the average losses caused by important operations and serious injuries we shall never learn. One thing is certain, that they were much greater even than most of the available calculations let them appear. But this second fact is just as certain: that the setting up of average numbers had at that time scarcely any value, because the mortality was subject, at different times, in different hospitals, and under different surgeons, to the most enormous variations, as a glance into the celebrated work of Malgaigne will show. Average numbers can only be of value when the variations take place within certain fixed limits. The high tables of mortality of old surgery have been obtained by the additions of series of cases which differed from one another fivefold or tenfold; and as soon as they were applied by the sick-bed or in the judgment of the results of treatment, they let any result appear satisfactory, and if fatal, excused it.

We may therefore say without exaggeration that the old statistics of surgery were of no use, but only did harm, and we may oppose to their sad, unsatisfactory figures, the simple demand that *no* person should die of an injury unless its severity directly threatens his life, and that no person injured or operated on should perish through a secondary inflammatory disturbance developed from the wound. Every loss of this kind may be traced to some mistake on our part.

But we, who have ourselves groaned beneath the weight of the old surgery, and have now made the new our own, possess comparative statistics that are infinitely more valuable to us than all the numbers that our opponents have held up against us—statistics which we have fought for in the last few years. The time is long enough to have excluded all the old theories of chance. During ten years it is not possible to be always lucky, always to have good cards, as even Pirogoff still ventured to assert of certain privileged surgeons.

And if we compare our former with our present results, we find a difference like that between day and night, the feeling of a great victory after long and severe defeat; and never do I feel more solemnly and gratefully inclined to Providence, who has permitted me to live to see this blessed change, than when I make this comparison.

Professor Nussbaum has drawn this comparison between then and now in his clinic in clear traits, and with manly candor; he has shown that for forty years under his own direction, as well as under that of his predecessors, among whom was Stromeyer, fatal wound-diseases raged, that nearly all patients with complicated fractures died of them, and that even those with the slightest injuries often succumbed to them; that erysipelas and abscess were matters of daily occurrence; that during the latter years hospital gangrene also appeared and attacked the dreadful number of eighty per cent. of all wounds and sores; that he stood helpless and powerless before all these conditions, and that at one step, after the general introduction of the antiseptic method, all this ceased, and instead of that, even after great operations, healing by first intention was introduced as an entirely new result.

I have also tried already at the third German Congress of Surgeons to draw a similar comparison; it is not essentially different from Nussbaum's. Since then a long series of years has elapsed; and in all countries, but perhaps most of all in Germany, a great mass of experience has been collected, and it might perhaps be now possible, by a comparison of large numbers, to discover, with some amount of certainty, what are really the chief questions: How far have we got in the control of accidental wound-diseases? What dependence is to be placed on our present technical aids? Where and how often do they leave us in the lurch? and Where are the limits to our present power placed? Time and place do not permit me to make this attempt, and perhaps it would be beyond my power. But, with your permission, I will lay before you some few data bearing on these questions, and if I take these chiefly from my own experience, you may be convinced that this is only because these are most accessible to me, and because I can myself vouch for their accuracy. For the satisfaction of personal vanity I should probably have chosen another subject than this, which shows what can be achieved by a method in the invention of which I had no share, and should have brought forward other results than those which were achieved by submitting entirely during the first years to the prescriptions of Joseph Lister, and resisting every temptation to do better and more simply than he. Most of the unfavorable judgments passed on this method are due to the fact that surgeons who had not yet learned to experiment with it already made it the subject of their experiments.

Two examples will suffice, compound fractures and major amputations. The mortality after compound fracture had, during the long labors of my predecessor as well as during my own, reached the sad height of forty per cent. When I adopted the antiseptic treatment of wounds, my last twelve patients, with compound fracture of the leg, had all died of pyæmia or septicæmia. From that time up to the present day I have treated, one after another, one hundred and thirty-five compound fractures, and not a single patient has succumbed to either of those accidental wound diseases; one hundred and thirty-three were cured, two died, one of fatty-embolism of the lungs, during the first few hours; and one, a drunkard, of delirium tremens.

For amputation one assertion will almost suffice, which I beg you to regard seriously: I now cure, every year, more cases of amputation of the thigh than during all the rest of my labors before the introduction of the antiseptic method. The number of amputations of the larger limbs which I have undertaken during the last few years amounts to more than four hundred. If I subtract those cases where death did certainly not result in consequence of the operation, but independently of this from some other serious complication, there results a mortality of four to five per cent., and the same number, so far as I can discover from the communications before me, was obtained in the other German hospitals in which antiseptic surgery is practised in full strength.

My friend Dr. Schede has made a calculation which will, I believe, interest you. He has studied the reports of a great number of amputation cases of the old period, so that he was able to distinguish those in which death resulted from pyæmia or septicæmia—those therefore which we now save—and the mortality of the remaining cases also amounted to about five per cent. In these four to five per cents., besides those fatal cases caused by mistakes in treatment, those are also included which in amputations after serious injuries must be laid to the door of the shock caused by the previous serious loss of blood. We may therefore declare that amputation of the larger limbs has been almost absolutely free from danger—at any rate, much less dangerous than many small operations were formerly, whose mortality was never discussed. After extirpation of sebaceous cysts in the head, occasionally one or other of those operated on perished; and a by no means small part came off only with their lives. It is true, I must disguise the fact, that my numbers have been slighted. It has been said that I kept back the unfavorable cases, and thus improved my figures of mortality. Quite lately a French colleague of mine declared that in France it would not be possible to agree to my sort of statistics!

But, gentlemen, what do we want? Do we want to count the amputated limbs like fallen apples, which are picked up from under the trees? Or do we want to gain figures that answer questions which have a practical importance? If we want to know how dangerous *per se* is amputation at the upper part of the thigh, we cannot learn this from the patients who already suffer from severe septicæmia, or who, besides, suffer from severe brain injuries; and if we want to know how dangerous it is to remove the thigh, we cannot make use of cases where both have been amputated. But I will not complicate these statistics in order, as my opponents say, to contrast the most favorable with the most conceivably unfavorable cases. During the time of which I speak, fifty-seven large limbs were amputated—lost according to common parlance—because of acute progressive septic processes, chiefly patients with severe open fractures, wounds of the joints, and laceration of the soft parts, who were brought to us too late from the country, cases of embolic mortification and large putrid abscesses. All patients in whom signs of mortification had shown themselves, not counted. Of these fifty-seven amputated cases, in which, in almost half, the operation concerned the thigh, fully seventy per cent. were cured. A mortality of thirty per cent. is lower than I formerly attained to in cases of primary amputation. It shows best how erroneous are the views of those who contend that antiseptic surgery can only attain results in prophylaxis. Far more rapidly than by means of figures and a survey of successes, we can attain to a comprehension of the enormous advance achieved by modern surgery when we see what is actually done in the domain of operations—what is held permissible, and what is done and risked daily without danger to the patient. For this it is not needful to be a surgeon, not even a doctor, in order to testify to the changes that have come about. Operations are now conducted which fifteen years ago would have been regarded as madness, or as crimes. And often it is the younger doctors who have not had much experience of independent practice who have this advantage over their more venerable colleagues—that they have faith in the infallibility of the antiseptic principle, and have a courage that has not yet been daunted by ill-success; and it is they who venture upon operations of which formerly the most daring surgeons did not think, and attain results concerning which these shake their heads.

But do you think, gentlemen, that one of us older ones could so easily take up the idea of Ogston's operation? For this one must be young, and have grown up in the new thoughts and surroundings, and only know the sad experiences of older surgery as a legend. It is far from me to wish to discuss the value of the operation for the cure of genu valgum. I only wish to show from what one does not shrink. It will always remain of historical interest that, a few years after a great war, in which we were obliged to let the greater number of our wounded die in whom a ball had pierced the knee-joint capsule without hurting the bones; we dared to saw off in the dark within the joint a condyle, leaving blood and sawdust behind. Further, it would be easy to produce numbers of as apparently venturesome operations of which no one doubts the necessity or that they should be permitted.

For a large enchondroma in the costal pleura that occupied the left wall of the thorax, Prof. Fischer removed a large piece of the chest-wall and ribs, so that the heart and lungs were exposed and an opening as large as a child's head was made, and yet the patient was able to be discharged from the hospital after four weeks.

In the case of a large echinococcus of the liver, which in front and at the side was covered with thick layers of liver tissue, and which projected into the thoracic cavity after resection of the seventh rib, I opened the healthy pleural cavity, which was free from adhesions. The thorax was freely open, the thinned diaphragm cut into, the echinococcus sac opened, the animal bladder extracted *in toto*, and the patient recovered without complication. A similar operation, with like results, was conducted by Mr.

Israel, of Berlin. Mr. Hahn, also of Berlin, in two cases of wandering kidney, where the mobility and the discomfort induced thereby had attained an unusually high degree, drew out the organ in question through a large wound in the loin, and sewed it into the same. Both patients recovered and lost their pain. The opening of the joints seems a most innocent performance. Hips and knees are cut open in order, in a case of luxation, to search for the obstacle which opposes itself to reduction, in order to suture the ruptured tissues, and in obscure symptoms to clear up the diagnosis *in vivo* by means of autopsy. More than two hundred times I alone, without in one instance bad results following, have incised, drained, and washed out diseased knee-joints without exciting suppuration.

Bone and marrow tissue will submit to every kind of treatment without putrefying and without suppuration. Orthopædics celebrated their greatest triumphs in the saving and straightening of limbs. We read that Mr. McEwen alone has performed 835 osteotomies, of which 827 were healed without suppuration, and he lost no patient from the operation itself or from its consequences. To facilitate the healing of empyemic cavities, Mr. Schneider resected from six to nine ribs, and even also the clavicle. In very painful cases of syphilitic hyperostosis I myself have repeatedly exposed the tibia in its whole length, and knocked off with a chisel a whole handful of bone shavings. The cure was rapid; the pains disappeared. The old opinion that in cases of strumous suppuration wounds heal less well has been set aside—the largest scrofulous abscesses, even if they come from the spinal column, can be opened not only without danger, but often healed in a brief time through a special kind of first intention. The feat of excision of part of the stomach has excited the whole world, perhaps to excess, since the same operation has been already effected upon the intestines with the happiest results. Weak, paralyzed persons, who usually are anxiously shielded from every injury, have had their main nervous system exposed, to subject it to thorough manipulation.

And now leave the writings and let us realize the teachings of the greatest masters of the first half of this century, of those who were equally great as doctors and as men; for instance, Sir Astley Cooper, whom we may regard as the representative of the highest development of the older surgeons, and you will be convinced that their firm and leading principle, the moral standpoint on which they stood was this, that every operation is dangerous, and should, if possible, be avoided. There is not one of us who, led by B. von Langenbeck, did not stand on the same ground during the great wars of 1866 and 1870. in his treatment of the wounded. Only since 1870 the new views have forcibly made their way.

Cast a glance at the surgical clinics of hospitals, where these are conducted by men who have willingly given up the hardly won results of their own work, and have entirely adopted the knowledge and power of our new art, and here too you will see the greatest changes; cases of operations and wounds without fever and pain, a happy result being regarded as certain; no traces of blood and wound secretions on the bandages, let alone on the body and bed-linen; disappearance of that incessant activity of untrustworthy and senseless assistants, the continuous putting on and taking off of compresses and cataplasms, the regular change of bandages repeated every morning and evening. It would thus appear that in association with anæsthetics and the bloodless method, antiseptic surgery has deprived all important operations of their terrors. Certainly the preparations for an operation are often tedious, the first cleansing and preparation of a fresh wound circumstantial and lengthy, but with the first dressing an immense amount of work has been obviated, which formerly extended over the following weeks and months. The later course, the fate of the wounds of the patient, is as a rule determined and assured by this first dressing; we can often heal an amputation wound with one or two dressings.

Our views on the nature of contagia in the surgical department of hospitals, on their origin and breeding-places, have entirely changed. There is no hospital that is so bad that it can excuse failure in the treatment of wounded and operated patients. If we had no other task in the treatment of our sick but to guard against the purely relative interruptions of the normal process of wound healing, we could be content with the old close and over-filled houses, and the splendid piles we now erect would be superfluous. We well know plague-stricken hospitals where, from wound to wound, from sponge to sponge, from compress to compress, fungous formations in countless generations have grown to the highest degree of adaptation to the fluids and wound secretions of the human body. But it lies in our power to disinfect them. By no ventilation in the world can septicæmia, pyæmia, and erysipelas be blown out of the hospitals; not even by the most assiduous care in ordinary life can they be avoided, but only by the conscientiousness and prudence of the surgeon. If ever the excellent Simpson was right in his assertion that far more operated patients die in hospitals than in private practice, modern surgery may rather declare the contrary. If there is any danger of a mistake in the treatment of a wound, it is more likely to happen in a private house, where it is more difficult to satisfy the accurate demands of modern surgery than in the hospitals.

Gentlemen, weighty circumstances and daily occurrences have always made surgeons as well as laymen recognize the importance of those problems which are solved by the discovery of the mycotic nature of wound diseases. The contrast between open and subcutaneous wounds must have been known as long as men have worked hard and have fought each other with weapons. And not only was this known, that simple fractures are not dangerous and heal without suppuration, but also the experience had been gained that there will be no suppuration, no matter if the individual concerned is young or old, robust or decrepid, scrofulous or syphilitic—whether he has this or that constitutional condition, this or that individual disposition. And this also has long been known, that the danger in a compound fracture is very great, if only on the lower thigh the skin, very poorly supplied by nerves and vessels and scarcely for an inch in area be sharply perforated by one of the fractured ends. But the consequences of these facts were not seen. They were too much opposed to the prevailing doctrine which regarded not only the suppuration, but also the serious disturbances resulting from it, as only *quantitative* increase of the process of reaction following on the injury. The whole of antiphlogistic therapeutics was based on this supposition. And yet the history of fractures might long ago have afforded the most conclusive proofs that it could not be the intensity and extent of the injuries of the tissue which determine the severity of the inflammation and the suppuration that these latter had in reality nothing to do with

the traumatic reaction, but must be some other thing essentially different. For even a good number of simple fractures are by no means such simple things as was formerly imagined, since they often do not occur without serious crushing of the marrow, tearing off of the periosteum, laceration of muscles, fissures, and splinters; certain forms of fracture, especially those of the cervix femoris, and of the spine, are good examples of destruction and crushing of the tissues. And yet even in these cases, suppuration of the greatest intensity does not occur. To attain the conviction that mechanical obnoxious influences, however severe, cannot of themselves produce suppuration, no myologic examination would have been required. The importance of this fact was only revealed to me in its full bearings in examining the wounded on the Bohemian battle-fields. Among the great number of gunshot fractures which I had to treat there, there was a not inconsiderable number of cases where cure resulted after the usual course, as after a subcutaneous fracture without suppuration and without discharge of splinters; and I considered it obvious that here only that explanation was admissible which Stromeyer had given to these cases—namely, that the ball, passing at a tangent, had broken the bone flat, as in the simplest subcutaneous fracture. But of those so successfully cured, two of those who had been injured in the upper part of the thigh died from the results of other wounds inflicted at the same time; and when I examined these supposed bone-fractures, I found to my surprise that just here the most extensive destruction had taken place. In the one case twelve splinters, in the other about twenty, of a size varying from several inches to that of a pea, were caked together by fresh callus without any suppuration or necrosis, and in another similar case there lay firmly enclosed in the callus a little piece of cloth from the uniform.

Then, in the year 1870, Professor Klebs discovered that even in the internal organs, which are considered so vulnerable—as brain, lungs, and spleen—no inflammatory reaction occurs, if the path of the bullet is so long and narrow that it prevents the admission of air; and that even weeks afterward, macroscopically, no changes can be traced in the tissues shot through, while microscopically the process of healing can only be recognized by a minimum of cellular activity.

And now antiseptic experiments, which exclusively belong to Mr. Joseph Lister, to whom I therefore here offer a small part of the gratitude that German surgery owes him, show us that, after an amputation, on the fourth or sixth day the ends hang down in just as limp and unchanged a manner as immediately after the operation, just as if it had been performed on a dead body and not on a living being; that after a great plastic operation, in spite of countless sutures, no trace of œdema or reddening and no pain occur. India-rubber tubes passed through dropsical joints may remain lying there for weeks without causing suppuration, and they may, slipped unnoticed into the cavity, heal so firmly into the armpit that a year after they may be mistaken for well-defined cancer tubercles, and be extirpated. Into the open peritoneal cavity a piece of gauze, larger than a table napkin, and pressed together like a handkerchief, can be put, and remain for several days without fever or clinical appearances of fever resulting. And I should like to mention one more experiment, which, it is true, will not always succeed. Suppose we have a case of limited fistulous caries of the foot before us; five or six times we introduce the glowing Pacquelin cautery iron to the depth of an inch and a half, and carbonize the dissected tissues. Then we cut the skin in a circle round the former fistula at a breadth of two lines, and let the blood, mixed with a disinfecting fluid, flow into the deep spherical cavity, fill it out, and coagulate. In a fortnight or three weeks the upper layer of the coagulum scales off, and the burn is cicatrized without any reaction, suppuration, or falling off of the scab. So that in man also Professor Hueter's five experiments on animals are confirmed.

After such facts, there can be no further doubt that we have hitherto studied traumatic reaction of open wounds on tissues infected at the same time that the four cardinal symptoms of inflammation—robor, calor, tumor, dolor, even in the severest open wounds—are not developed when disturbing agencies have no access, or do not find soil fitted for their development.

Seriously, we have now to consider the question whether mechanical irritations, such as the surgeon's knife and saw cause, and the injuries of the social life, are at all capable of alone bringing about those processes which have at all times been designated as inflammatory.

I do not consider the latter question as yet fit for decision, although the extreme radicals already advance weighty reasons to refuse even to thermic and chemical irritants the power of causing inflammation; so long as in the erythema of burns and the dermatitis from iodine painting, associated with abundant exudation of leucocytes, the influence of organic germs is not proved, and so long as the same proof is wanting for carbolic erythema, I believe that we ought at any rate to wait for results of further investigations.

Gentlemen, I have touched on traumatic reaction of the tissues to show how distinctly modern times have influenced even the oldest dogmas of our science; how we are obliged to abandon almost everything that our schools have taught us in order to gain for our scientific opinions a newer, firmer foundation.

I am coming to an end. I have already occupied your attention for a longer time than may appear fitting to some of you. I have spoken of the advances in surgery. There is one I have not yet mentioned. It has never hitherto been so deeply and universally realized that the interests of our practice must coincide entirely with those of our patients; never before was the feeling of responsibility for our actions so great as at the present day. The breach which divides us from the older surgeons is immense here. We do not refuse to let our capability be entirely measured by our successes. For even if the surgeon of former times willingly submitted to this measure, when it was only a subcutaneous fracture without essential displacement or the straightening of a club-foot that was to be dealt with, yet, as soon as it was a matter of preserving life after an operation, or even of preventing serious disturbances, he might decidedly reject this standard. No surgeon, however learned and skilful he might be, would have been willing then to promise or guarantee, or in case of ill-success to reproach himself; he is almost certain in this important point to have, like every other surgeon, the sad privilege of not being responsible for uncontrollable circumstances.

To-day we may say, with the deepest conviction, that the surgeon is responsible for every disturbance that occurs in a wound; that it is his fault if even

the slightest reaction or redness is developed in it, or if an amputation is not healed by first intention. He must reproach himself severely if after an operation bagging of pus occurs, and especially if death occurs from pyæmia. He who cannot attain to this degree of perfection may be converted from his former method of treatment to antiseptic methods like one who having hitherto always prescribed senega for catarrh, now uses ipecacuanha. Of the storm that has swept over the fields of surgery during the past ten years he has not experienced a breath.

Justice requires us to recognize that the higher moral aspect of this question has come to us from England. It was the English ovariotomists, with Mr. Spencer Wells at their head, who first showed us how to approach an operation at that time looked on as fatal, how to take on one's self the whole responsibility of success or failure, and to keep no other goal in view than this one, to save the patient, and, by a constantly improving and perfecting of our art and carefully keeping everything injurious at a distance, gradually to become more and more master of one's actions. At that time we began to recognize that at the operating-table there are other matters of importance than to shine by quickness, elegance, and security in the use of the knife.

Yes, gentlemen, our labors have become more blessed and more joyful. We know that a great responsibility rests upon us, but we also know that with honest will, knowledge of our subject, and use of all our powers, we are able to satisfy its demands. And because we believe that this feeling of responsibility is living and constantly increasing in the younger generation, we trust that surgery will overcome the dangers that doubtless lie in the rapid changes it has experienced, and is being led toward a further development.

---

Statistics of Registration.—Dr. S. A. Hills, of this city, sends us the following statistics, compiled from the recently published list of registered physicians: Of the number registered, between twenty-three and twenty-four hundred, the graduation is as follows: College of Physicians, New York, 554; College of the University of New York, 424; Bellevue Medical College, New York, 250; Medical College of New York, 7; New York Medical College, 47; Medical Society of New York (this includes county and State), 31; New York Medical College for Women and Infirm, 69; Homœopathic Medical College of New York, and other like schools, 119; Eclectic Medical Colleges in New York and elsewhere, males, 104; females, 17—121; New York Medical College for Women, 6; female physicians, total, 101; from colleges in New York outside of city, 78; New England medical colleges, 100; Central and Western States (except New York City), 134; Southern States, 62. Abroad—Berlin, 23; Vienna, 17; Würzburg, 25; Munich, 8; Gissen, 8; Paris, 17; England and Ireland, 33; German States and Central Europe, 164. One or more from such sources as the following: Commissioned by Governor Seymour, 1; by authority of the United States, 1; German Government, 1; Botanic Medical College, Ohio, 1; State Board of Health of the free town of Frankfort-on-the-Main, 1; Russia, 3; Italy, 5; Commission of Prussian army, 1; Baltimore College of Dental Surgery, 1; Licensed by copyright granted by the laws of the United States, 1; and others.

# International Medical Congress.

*Held in London, England, August 3 to 9, 1881.*

(Special Report for The Medical Record.)

## MEETINGS OF THE SECTIONS.

### SECTION ON DISEASES OF THE THROAT.

The first paper read was one of great interest to all laryngologists, as in it Signor Manuel Garcia detailed how it came to pass that he invented the laryngoscope.

Dr. Vivian Poore's case of web in the larynx, probably congenital, excited considerable interest, the general opinion being that, though these cases were not necessarily congenital, the one before the meeting certainly was.

Dr. Rumbold's (St. Louis) paper went to prove that the spray-producer was the only plan which removed morbid secretions from the affected surfaces without causing the least irritation.

#### THE TREATMENT OF DIPHTHERIA.

In opening the discussion on diphtheria, Dr. Morell Mackenzie stated that, so far as local treatment was concerned, he placed his sole reliance on varnishes—*i.e.*, remedies which exclude the air from the false membrane—tolu dissolved in ether being the most serviceable. There was an almost complete unanimity against the forcible removal of false membranes or the cauterization of the affected surface. Ice in the early stages, steam inhalations, with or without antiseptics, in the later stages, were generally recommended. Lactic acid and lime-water were praised as being the best solvents, and boracic acid as an antiseptic. In opposition to the views generally held, Dr. Meyer brought forward for Dr. Nix, a Danish medical practitioner, his plan of treatment, which consisted in scraping away the false membrane and cauterizing the scraped surface with solid nitrate of silver.

Dr. Lennox Browne recommended the removal of enlarged tonsils, even during an attack of diphtheria, if they offered any impediment to respiration. In the discussion on the "Pathology of Laryngeal Phthisis," there was great difference of opinion both as to the early recognition of the disease and its diagnosis from syphilitic ulceration. Professor Krishaber, of Paris, considered the diagnosis of tuberculous laryngitis during the patient's life very easy, whereas Professor Rossbach, of Würzburg, was of opinion that certain diagnosis of laryngeal consumption was only possible if pulmonary consumption be simultaneously present, otherwise tubercular and syphilitic ulceration can only be distinguished from each other by their different behavior to iodine. On the other hand, Dr. Fränkel, of Berlin, said that the treatment by iodide of potassium would not differentiate it from syphilis, as tuberculous ulceration sometimes heals under the iodide. As regards prognosis, the view of the laryngologists who spoke was more hopeful than that generally held by physicians. Professors Gerhardt and Rossbach (both of Würzburg), asserting their belief in the absolute curability of the disease.

#### THE MOTOR NEUROSES OF LARYNX.

The discussion on the motor neuroses of the larynx centred chiefly on the clinically and anatomically proven fact of the proclivity of the abductor

fibres of the recurrent nerve to disease, both central and peripheral. Professor Gerhardt, who introduced the subject, was opposed, in the present state of our knowledge, to any premature hypothesis to explain this curious fact. The papers introducing the discussion on "Neuroses of Sensation of the Pharynx and Larynx" were very opposite in character, that of Professor Schnitzler, of Vienna, being a short, practical one, whereas the one sent in by Professor Elsberg, of New York, and read (in part) by Dr. Morell Mackenzie, was very elaborate.

THE FORMATION OF MUCUS IN THE LARYNX AND TRACHEA.

In discussing the formation of mucus in larynx and trachea, Professor Rossbach pointed out that the secretion was independent of central nerve influence. Dr. Fränkel drew attention to the fact that the conditions in the trachea on which the author had based his statement were different from those in the nose and pharynx. Dr. Bayer, of Brussels, in his paper on "Influence of Female Genital Organs upon Organ and Formation of Voice," detailed all the possible consequences of this connection. Drs. E. Fränkel and Semon insisted that the prognosis in these cases ought to be guarded, as even when apparently dependent upon uterine disease, the cure of this latter was not necessarily followed by the cure of the laryngeal trouble. The discussion on "Indications for Extra or Intra-Laryngeal Treatment of Growths in the Larynx," which was opened by Dr. Fauvel, of Paris, and Professor Burow, of Königsberg, affirmed the statement of the latter, that only when an experienced laryngologist has established the inexpediency of the intra-laryngeal treatment may the extra-laryngeal method be adopted; the only marked exception being in favor of thyrotomy in certain cases. Dr. Solis Cohen, of Philadelphia, and Professor Lefferts, of New York, were, however, rather more in favor of the extra-laryngeal mode than their German *confrères*, but even they limited it to exceptional cases. There was a general agreement with Dr. Semon that of necessity the removal of intra-laryngeal growths must remain in the hands of laryngologists who had devoted special attention to the subject.

REMOVAL OF LARYNGEAL GROWTHS.

Professor Krishaber pointed out that in children the removal of laryngeal growths may be accomplished with comparative ease, by guiding the forceps into the larynx by means of the forefinger, and seizing the growth without the aid of the mirror.

Dr. Hering's (Warsaw) paper on "Results of the Mechanical Treatment of Laryngeal Stenosis" was based upon statistics of all hitherto recorded cases, one hundred in number. He attributed the want of success reported as not due to the insufficiency of the method, but evidently to want of patience on the part of the patient or surgeon, or to the non-adaptability of the plan of treatment to the particular case. This view was agreed to by all who took part in the discussion.

The discussion on "Indications for the Complete or Partial Extirpation of the Larynx," which was opened by Dr. Foulis, of Glasgow, revealed a great difference of opinion between the surgeons and the laryngologists, the former being disposed to include a larger number of cases among those suitable for the operation than the latter. Professor Czerny, of Heidelburg, to whose careful experiments we are indebted for this operation, was present and spoke on the question.

Professor Voltolini, of Breslau, the oldest advocate of the method, introduced the discussion on the "Galvano-Caustic Method in Nose, Pharynx, and Larynx." The general opinion was in favor of this plan in the nose and pharynx; in the larynx its utility was more doubtful. Some of the speakers, notably Dr. Foulis, dwelt on the advantages of the actual cautery.

PATHOLOGY AND TREATMENT OF NASAL CATARRH.

In his paper on the "Pathology of Nasal Catarrh," Dr. Bosworth, of New York, asserted that rhinitis atrophica was a primary affection, and not a secondary stage of the hypertrophic variety.

The subject of "Adenoid Vegetations in the Vault of the Pharynx" was introduced in an exceedingly able paper by Dr. Meyer (Copenhagen), to whom the credit of having first directed attention to these growths must be assigned. His statements were supported by Dr. Lowenberg (Paris) in his introductory paper. Both remarked on the frequency with which this affection is overlooked, and dwelt on the importance of drawing more attention to it, as it is so frequently the cause of ear troubles, nasal voice, and nasal respiration, and even affections of the conjunctiva. These growths are almost exclusively met with in childhood and youth, hardly ever occurring after the age of twenty-five. As regards treatment, very different methods were suggested, the most remarkable of which were those brought forward by Drs. Meyer, Lowenberg, and Guye.

The discussion on the "Nature and Treatment of Ozæna" elicited a great difference of opinion. Dr. Krause's view that the fetor, which is such a prominent feature in these cases, was due to the formation of fat and the decomposition of fatty acids, did not find any supporters. For the palliation of this disease, which all agreed was not curable in the strict sense of the word, syringing after Michel's plan and the use of Gottstein's tampon were recommended.

The demonstration of patients, instruments, etc., for the Sub-section of Diseases of the Throat took place at the Hospital for Diseases of the Throat and Chest, Golden square, and was very numerously attended.

Dr. F. Semon showed an interesting series of five cases of bilateral paralysis of the abductus, on one of whom he had to perform tracheotomy for the relief of impending death from asphyxia, and one case of anchylosis of the crico-arytenoid joint.

Dr. Poore exhibited a patient with a web in the larynx, probably congenital.

Professor Krishaber brought for inspection a set of tracheotomy tubes; he stated that there is a definite relation between the height of the body and the diameter of the trachea, consequently the size of the tracheotomy canula should be adapted to the patient's height.

Dr. Foulis showed an apparatus for heating the actual cautery, also instruments for removing larynx, artificial larynges, and two larynges he had removed.

Dr. Cresswell Baber exhibited a self-retaining nasal speculum, and a snare which could be fixed at any angle.

Dr. Michel demonstrated his method of removing adenoid vegetation by means of the galvano-caustic loop.

Dr. Fränkel exhibited a mouth dilator, a modification of Whitehead's, with the addition of a palate hook. This may be regarded as one of the most valuable of the instruments exhibited. He also

showed a prism for inspection of the cavities of the body.

Dr. Morell Mackenzie sent a patient on whom he had performed internal œsophagotomy, and a case of spasm of the tensors of the cords, and showed his œsophagoscope. Störch's œsophagoscope was also shown.

TREATMENT OF SYPHILITIC STENOSIS OF PHARYNX.

Dr. Whistler exhibited a patient with syphilitic stenosis of the pharynx, in whom he had established a communication between the pharynx and posterior nares. Dr. Cadier exhibited his tube laryngoscope, a most inconvenient and unpractical instrument. Dr. Tornwaldt showed a tampon filled with water for the dilatation of laryngeal stenosis. Dr. Bosworth brought forward his mode of removing polypi, insisting on the advantage of using No. 5 steel piano-wire. Dr. Rumbold showed his spray producers; Mr. Spencer Watson a self-retaining nasal speculum and other instruments for the treatment of diseases of the nose, and Dr. Prosser James a series of laryngeal lancets and probes, each being forged out of one piece of solid steel.

On Monday afternoon a supplementary demonstration of instruments, etc., took place. Professor Voltolini showed his battery and demonstrated an ingenious mode of removing needles and other articles of iron from the larnyx by fixing them by means of a powerful magnet, and then introducing a knitting-needle, to which they attach themselves. Professor Caselli showed his galvano-caustic tracheotome, Dr. Meyer exhibited the instrument he employs in the removal of adenoid vegetations, and Dr. Böcher an improved form of lamp for laryngological and other purposes. Dr. Goodwillie demonstrated the use of a surgical engine for the removal of exostoses, etc.

## SECTION ON MENTAL DISEASES.

THE CARE OF THE INSANE.

In the discussion on the paper of the President, Dr. Lockhardt Robertson, the consensus of opinion pointed to the necessity for a greater use of the county asylums for the purpose of instruction; that in this way only could opportunities be afforded to every student to enable each to obtain such an acquaintance with insanity as would prepare him to answer a question on this subject at his examination by the licensing bodies; and that a special course of study should be demanded of all medical men who were empowered to sign certificates of insanity.

TESTAMENTARY INCAPACITY.

Dr. Bucknill, in his paper on "Testamentary Incapacity," specially discussed the recent decision in Banks *v.* Goodfellow, wherein the Court of Queen's Bench found a person capable of making a will who was admittedly the subject of delusions of suspicion and persecution.

Dr. Maudsley pointed out that this was a sequence of similar American decisions, and commended the recognition of the ability of some cases of hallucinatory insanity to execute a will. In this opinion he was supported by Drs. Wood and Orange.

Dr. Motet, of Paris, alluded to the difficulty of deciding this question in cases of coarse brain disease with mental enfeeblement, and Dr. Bucknill quoted the case of a patient in a private asylum who had lately, under his advice, executed a will with appropriate legal precautions.

HYPNOTISM.

The subject of hypnotism was introduced by Professor Tamburini, who has without doubt taken the truly scientific method of examining, in the most exhaustive manner, the condition of the circulation, respiration, and muscular irritability, as well as the reactions of the senses during the hypnotic state. By this method only can deception and imposition be eliminated from this matter and the subject brought to have a definite scientific value.

Dr. A. Foville, in an interesting paper on Megalomania, established two forms of exalted delusion: the first fleeting, inconsistent, and generalized, occurring in general paralysis, transiently in mania, in organic brain disease, and in alcoholism, in all these conditions being probably related to hyperæmia of the cortex of the brain. The second variety is systematic and permanent, chronic in evolution and incurable; usually associated with hallucinations, with delusions of persecution, and exalted change of personality, and being especially associated with illegitimacy.

CEREBRAL LOCALIZATION AND HALLUCINATIONS.

Professor Tamburini, in his paper entitled "Cerebral Localization and Hallucinations," stated that Panizza, in 1856, recognized the existence of a sensory centre (of sight) in the cortex cerebri, but that the full development of the discovery was due to Ferrier. He endeavored to prove that hallucinations are caused by disease of the sensory cortical centres.

Dr. Ferrier, in alluding to the distinct regions of special sense in the cortex cerebri, proved by his experiments before the present Congress, suggested that hallucinations should be regarded as sensory convulsions, analogous to those occurring in motor centres.

Dr. Alexander Robertson, in his communication on unilateral hallucinations, relegated their origin to the sensory centres, which, however, he did not at present consider to be satisfactorily mapped out.

Dr. Fournier attempted to prove that hallucinations differed only from ordinary acts of memory in being involuntarily and unconsciously originated. An abnormal stimulus thus arising in the cortex was transmitted to the optic thalami, and by reawaking of the activity of these organs gave rise to a false impression.

This theory met with very general opposition.

Dr. Fournier suggested the classification of hallucinations into those connected with: (1) The sensations of organic life; (2) the sensations connected with reproduction; (3) the sensations of the special senses; (4) the sensations produced by the voluntary activity of our organs, as by speech.

Dr. Motet's paper on "Moral Traumatism in the Alcoholic" had a medico-legal as well as a clinical interest in directing attention to the possible development of transient mania (not of the type of delirium tremens, but more nearly resembling the maniacal outbreaks after epilepsy) as a result of mental shock in a person of alcoholic habits.

Mental stupor was discussed in a valuable paper from Dr. Hack Tuke. He described three cases in which this condition was associated with catalepsy, and expressed the opinion that on a close examination most of these cases would be found to be due to melancholic absorption, and that in comparatively few was the mind an utter blank. He proposed to

abolish the use of the term "acute dementia," using the term "mental stupor" instead, and adding the words "with melancholia" when this was associated.

Dr. Foville alluded to the fact that the term "acute dementia" was no longer used in France, and that only one condition was recognized. On the other hand, it was urged that there was a distinct difference between anergic stupor and stupor with melancholia, although in some cases the distinction was difficult, owing to the conditions closely approximating in the later stages of disorder.

EPILEPSY

was the subject of a demonstration by Dr. Lasègue, who described true epilepsy as being due to malformation of the skull, either idiopathic or traumatic; all other forms as being spurious or epileptoid, *i. e.*, those due to cerebral traumatism, organic lesion, and toxic or hysteric conditions. The true epilepsy (excluding the traumatic), dependent on malformation of the skull, follows only on its ossification, and invariably develops between the age of fourteen and eighteen years. The head is found on examination and measurement to be asymmetrical either laterally or antero-posteriorly, and this is accompanied by asymmetry of the face, the mouth especially being askew (strabismus buccalis). This form is never hereditary, nor is it transmissible to offspring. The first attack of epilepsy is identical in character with all succeeding attacks, therein differing markedly from the epileptoid forms. The attacks of epilepsy occur between 4 and 7 A.M., during the passage from the sleeping to the waking state. These patients are epileptics in everything. Dr. Motet stated that Dr. Lasègue's views were generally accepted in Paris, but no discussion in confirmation or opposition followed.

INSANITY AND ITS RELATION TO OTHER DISEASES.

Satisfaction must be expressed that the relation of insanity to other diseases would appear to be specially attracting the attention of alienist physicians. The relations of insanity to paralysis agitans was treated of by Dr. Ball, to exophthalmic goitre by Dr. Savage, and to gout by Dr. Rayner.

From Dr. Ball's paper and the discussion thereon, in which several additional cases were quoted, the conclusion may be drawn that insanity with paralysis agitans is more common than the limited number of recorded cases would appear to indicate; Dr. Mercier expressing the opinion that the mental defect, being negative, was often overlooked.

Exophthalmic goitre was associated with insanity in three cases reported by Dr. Savage, who draws attention to the fact that symptoms of this disease may occur in general paralysis of the insane, and gave a case in which this diseased state recurred during attacks of mental disorder, being absent in the intervals, this case being markedly improved by hyoscyamine.

Dr. Rayner quoted cases of insanity from retrocedent and latent gout, with others in which it was only an associated cause. The importance of the recognition of its presence with regard to prognosis and treatment was dwelt on, and a parallel drawn with the insanity resulting from lead and alcoholic blood-poisoning.

NERVOUS TISSUES SPOILED BY METHODS OF PATHOLOGICAL PREPARATION.

Dr. Savage has rendered good service to pathology in drawing attention to changes produced in nervous tissues prepared for microscopic section by hardening in spirit. These changes, he showed, are not to be distinguished from the so-called miliary degeneration. He also exhibited microscopic sections containing colloid and amyloid bodies, which were probably due to the mode of preparation. Dr. Benedikt expressed the opinion that the miliary bodies were normal, and not pathological. Dr. Holler, of Vienna, communicated a paper on a "Method of Preparing Large Sections of Human Brains," of which he exhibited specimens. The process is a development of Sankey's method, large slices being stained in carmine-ammonia, placed in Canada balsam, dried on object-glasses, and pared with tenotomy knives to the required thinness. These sections would be useful for anatomical purposes, but for histological and pathological observation it may be objected that they do not take a uniform plane.

THE BRAINS OF CRIMINALS.

Dr. Benedikt exhibited a series of fifty brains of criminals, in which he discovered, as a marked characteristic, a general coalescence of the typical fissures. This deviation from the normal type he termed "atypic," the same condition being present in hereditary insanity, epilepsy, and other low types of the human brain. Dr. Shuttleworth gave an interesting *résumé* of the cranial characteristics of idiocy, and Dr. Fletcher Beach exhibited brains of cretinoid and microcephalic cases, pointing out the close relation between the mental characteristics and the development of the convolutions. He quoted the observation he had made in common with Dr. Hilton Fagge in cretinoid idiocy that the thyroid body was absent and was apparently supplemented by fatty growths in the posterior triangles of the neck. His microscopical sections showed the defect of processes in the motor-cells of the brains of idiots.

## SECTION ON OPHTHALMOLOGY.

MR. BOWMAN, the President of the Section, began by referring to the great advances in ophthalmology since the time when the International Congress of Ophthalmology met in London in 1872. The isolation in which ophthalmology then stood had disappeared, and it now formed a fundamental part of medical science.

The speaker then took up the different subjects upon which papers were to be read during the ensuing session. Referring to the subject of antiseptic surgery, which was first to be discussed, he said:

"In the case of the organ of sight, specially constituted, and in some respects screened from injury as it unquestionably is, there are reasons why the application of precautionary antiseptic measures, though the principle of them must still assert itself, should take a somewhat special form. Owing to the local structural conditions they may apparently be often more simple, though the possible need of the more elaborate of them should never be allowed to fall out of view."

The other topics to be discussed were then alluded to and the special points which it was desirable to bring out were mentioned. Taking up the subject of color-blindness, the speaker said:

The precision of our modern methods of determining the accuracy of sight and of the sense of color has at length made it possible to urge with increasing earnestness, on authorities responsible for the lives of travellers, whether by land or sea, the necessity of enforcing adequate test examinations, not only on candidates before engagement, but subse-

quently at stated intervals, on all persons employed where good sight is an essential qualification.

"If this be important in regard to railway drivers, guards, and signal men, it is even far more so in the maritime service. On land each government is in a very direct manner held responsible to its own citizens, and accordingly much has been done of late years in several countries, though effectually I fear in very few, to institute strict periodical examinations under State authorization and control. As to these, perhaps, a very close uniformity through different countries is not so very necessary, however desirable. But it is matter of common and urgent concern to all nations that on the open seas, on coasts, and in harbors a uniform system should prevail as to the due and sufficient and periodical testing of the sight of those who may be in the position either to give or to observe signals, on the prompt discrimination of which a multitude of precious lives may at any moment depend.

"And I trust it may not be very long ere such a uniform system of tests as science can now supply, and also the obligation to put them in force among their own subjects, will be willingly accepted by all civilized states."

---

## SECTION ON DISEASES OF CHILDREN.

A paper was read by W. B. CHEADLE, M.D., on

THE EXISTENCE OF TWO DISTINCT FORMS OF ERUPTIVE FEVER USUALLY INCLUDED UNDER THE HEAD OF MEASLES, AND THE RELATION TO DISEASE OF SO-CALLED RUBEOLA, RÖTHELN, OR GERMAN MEASLES.

The author held that the rule that one attack of a contagious exanthem confers upon the individuals who experience it immunity from any further attack of the same disease, has been found to hold good with regard to measles as generally as in the case of scarlatina or small-pox.

Yet in two recent epidemics, both of them of severe and pronounced type, which followed one another in the same district within the year, it was found that the individuals who suffered in the first epidemic obtained no immunity from the second; and, further, that no previous attacks whatever of ordinary measles exercised any protective power against the second epidemic. Of thirty cases of this second epidemic in which absolutely reliable histories could be obtained, twenty-two of the patients had had measles before, and ten of these, under the author's personal observation, within the year.

Certain deviations from the common type, such as a shorter period of incubation, severe laryngeal symptoms, and other special features, taken together with the fact that previous attacks of ordinary measles conferred no protection, proved the disease of the second epidemic to be an essentially distinct exanthem. The question then arises whether it was a new and unrecognized form of eruptive fever, or the only other known form of measles, rötheln. The exceptionally severe and even malignant character of the disease at the outset would seem to negative the idea of rötheln, which is always described as a disease of an invariably mild type. But after weighing all the facts, the conclusion was arrived at that the disease was rötheln, which prevails not only in the slight form which is acknowledged, but in a severe and malignant form also, hitherto not recognized as rötheln, but erroneously described as an exceptionally severe variety of common measles.

## SECTION ON MILITARY SURGERY AND MEDICINE.

The speaker, PROF. T. LONGMORE, acknowledged the honor conferred upon him by his election as President, and welcomed the many foreign friends who were present. He referred to the fact that this was the first time in which a special section had been devoted to military surgery at the meetings of the International Medical Congress. The necessity of a special study of this subject was apparent, in view of the fact that military service so often called for great modifications in the management of medical and surgical cases.

The most urgent question for discussion was, he said, the manner in which the antiseptic treatment of wounds can be carried out in times of war. This question, more or less, covers and influences many of the other subjects put down for consideration, such as the advance of conservative surgery in field-practice, the treatment of injuries of blood-vessels in the field, improvements in field-hospital equipment, and several others. The experience that has hitherto been gained in the strict application of antiseptic principles to the treatment of wounds in the field, has been obtained only under exceptional circumstances, and is, comparatively speaking, still exceedingly limited; but, such as it has been, the published results have been so largely superior, both as regards saving life and also as regards the restoration of the usefulness of wounded parts, to the published results of any other methods of treatment in the field, that, so long as the difference holds its ground, we are morally bound to try and extend the practice.

The speaker then gave a description of the system by which help is arranged to be afforded to the wounded among troops on active service, according to the existing regulations of the British service.

The plan adopted for accomplishing the various objects of a

MILITARY MEDICAL SERVICE

may be conveniently divided into two parts, viz.: 1st, that for the medical service from the base of operations to the area of active operations of the army in the field; and, 2d, that for the medical service with the army itself. The hospital establishments belonging to these two divisions of the medical service were shown separately in two diagrams. They are, in a great measure, independent of each other, although connected and working in concert; and they differ in their qualities, administration, and in many articles of their equipment, although the officers and men of the army medical department serving in them are interchangeable. The establishments at the base of military operations and along the lines of communication with the army have more or less of a stationary character, while the others are organized for being as movable as the troops which they accompany.

The insular position of our country leads to complications in the medical preparations for war from which continental nations are for the most part free. Wherever a British army may be despatched for hostile purposes, whether it be on part of a coast belonging to a friendly ally, or whether it be a position secured by force from a hostile power, the establishment of a new hospital in the place is one of the first necessities experienced. This will form the base hospital. As soon as the army quits its rendezvous, new temporary hospitals become necessary. These are known as *stationary* field-hospitals, or intermediate hospitals. In front of

these, and still nearer the line of march, are the *movable* field-hospitals. Between these latter two establishments are the "advanced depots." Here a supply of medical and surgical supplies and appliances is stored, ready for issue to meet wants in the bearer companies and movable field-hospitals. This is the station, too, to which the sick and wounded are brought from the field by the bearer-company's ambulance wagons, and from which they are forwarded by vehicles obtained by the commissariat department to the stationary hospitals along the lines of communication with the base.

These comprehend the establishments between the area of active military operations in the field and the base. They are all properly officered, and are under a surgeon-general, who reports to the surgeon-general in chief.

The establishments with the army actually operating in the field are of three kinds: 1st, the regimental establishment; 2d, the bearer-company; 3d, the field-hospital. These were each described by the speaker.

In conclusion, he said: "It will be seen from the account I have just given, that the regulated plan of medical and surgical assistance for troops on active service is a very complete one, and that it anticipates all the wants that are likely to occur during a campaign. It is obvious that to carry out the arrangements when the strain of a general action occurs, and help is demanded for a large number of wounded, previous training, intelligence, and active exertion on the part of all concerned will be necessary for success. An adequate staff is provided by the regulations for the purpose. In all these arrangements the calamity of a state of warfare in Europe has been particularly held in view. But even in other parts of the world, even in half-civilized countries, the general principles of the system can be maintained; the manner in which they are carried out has alone to vary, according to the nature of the military operations, the condition of country, and other local circumstances."

---

## SECTION ON PHYSIOLOGY.

Professor Michael Foster, President, delivered the opening address. His remarks consisted of a very exhaustive historical review of the work done for physiology by Englishmen.

Beginning with Harvey, whom he with Huxley classed as "last of the ancients" rather than first of the moderns, he referred to that great man's work and to the proper estimate that should be put upon it.

Following him was Glisson, who, aside from his anatomical discoveries, first applied the term "irritability" to muscle. Thomas Willis (1660) studied the functions of the brain. Robert Boyle added to the knowledge of respiration and the true function of the lungs. Robert Hook added still more in this direction. He showed, by an ingenious experiment —viz., by keeping the lungs distended with a brisk current of air passing through them, that the central fact of respiration was the effect of the air on the blood, and not the movement of the lungs—a demonstration which I venture to regard as a cardinal fact in the history of respiration. Only a knowledge of the chemistry of the blood-changes was necessary to make the theory of breathing approximately complete. And that also was, though imperfectly, supplied by the labors of two other Englishmen, Hook's contemporaries—Richard Lower and John Majow.

The school of mathematical physiologists, who, incited by the example of Borelli and the influence of Newton, fancied that the calculus alone could solve the mysteries of the living body, made a stir in their day, without really advancing our science, and the works of the versatile Jacobite Pitcairne, of Keil and Jurin are justly forgotten. A little later on, the first Monro began the long series of Scottish celebrities; but he was an anatomist rather than a physiologist. Indeed, in the early part of the eighteenth century the centre of physiological activity was at Leyden, where the brilliant, fascinating Boerhaave was making a school of world-wide reputation.

Boerhaave passed away, and Haller became his intellectual successor. The eighteenth century ran more than half its course with scarcely a sign of physiological activity in England save one. And this came not from the older universities, for they, leaving their old catholic sympathies, were wrapping themselves in narrower studies; not from the wigged leaders of the College of Physicians, for they were wasting time and talents in fruitless discussions of the doctrines of the schools; not, indeed, from the profession at all, but after a truly English fashion, from the sister calling of religion. The Rev. Stephen Hales (1726) was the first to correctly study the blood pressure in the arteries, "which" said the speaker, "is, next to Harvey's discovery, the keystone to the physiology of the vascular system."

Hales' essays are indeed even to-day a mine of delightful observations and reflections. He not only exactly measured the amount of blood-pressure under varying circumstances, the capacity of the heart, the diameter of blood-vessels, and the like, and from his several data made his calculation and drew his conclusions; but by an ingenious method he measured the rate of flow of blood in the capillaries in the abdominal muscles and lungs of a frog. He knew how to keep blood fluid with saline solutions, got a clear insight into the nature of secretion, studied the form of muscles at rest and contraction, and speculated that what we now called a nervous impulse, but which was then spoken of as the animal spirits, might possibly be an electric change. And though he accepted the current view that the heat of the body was produced by the friction of the blood in the capillaries, he was not wholly content with this, but speaks of the mutually vibrating action of solids and fluids as an independent cause of animal heat, in a way which makes us feel that had the chemistry of the time been as advanced as were the physics, many weary years of error and ignorance might have been saved in science.

The next physiological light came from the barber-surgeons, from John Hunter, who, the speaker claimed, had physiological more than anatomical bent of mind. Still he added very little to physiological science because his ideas so far outran the knowledge of his age. Hewson and Joseph Priestly were men who in the latter part of the last century contributed not a little to the advancement of physiology.

The labors of Thomas Young on the physiology of vision were mentioned.

Of Bell's work Dr. Foster said:

"And, indeed, the Nemesis which ever follows after errors, be they even errors committed with the best intentions, or in spite of the greatest care, overtook Charles Bell. We justly honor him as the author of the distinction between motor and sensory fibres; but that was only a part of the whole system of his new idea. That was the part which he sub-

mitted to the touchstone of experiment; that is the part which has remained, and which continues to this day, more and more abounding at once in scientific fruits and in practical benefits to mankind. The rest of his views (his nervous circles, his paths within the cerebral-spinal axis, his respiratory nervous system)—and if rumor be true, it was on these that he most prided himself—he refused to submit to experiment. And what has become of them? Are they not forgotten, or remembered only as stumbling-blocks, and rocks of offence?"

In conclusion, the speaker described the work of Marshall Hall and that of some of the later English physiologists.

The great advances in physiology were not now made in England, he was forced to admit.

This was largely because the work was hampered by legal restrictions upon physiology. Referring to the necessity, for physiological progress, of vivisection, he quoted the words with which Willis ends his preface to the "Cerebri Anatome:"

"Nam aut hac via scilicet per vulnera et mortes per Anatomiam et quasi Cæsareo partu, in lucem prodibit verit as aut semper lalebit." "For either in this way, namely, through death and wounds, through dissection, and, as it were, by a Cæsarean operation, will truth be brought to light or otherwise will lie forever hid."

## SECTION ON PUBLIC MEDICINE.

Mr. John Simon, after a few introductory remarks, gave a sketch of the meaning and the scientific method of state medicine. Much stress was laid on the value of experimentation, and the distinction shown between scientific and popular experiments.

He referred to the fact that, during the last quarter of a century, all practical medicine (curative as well as preventive) had been undergoing a process of transfiguration under the influence of laboratory experiments on living things. The progress which had been made from conditions of vagueness to conditions of exactitude had, in many respects, been greater in these twenty-five years than in the twenty-five centuries which preceded them; and with this increase of insight, due almost entirely to scientific experiment, the practical resources of our art, for present and future good to the world, had had, or would have, commensurate increase. Especially in those parts of pathology which made the foundation of preventive medicine, scientific experiment in these years had been opening larger and larger vistas of hope; and more and more clearly, as year succeeded year, we saw that the time in which we were was fuller of practical importance than any of the ages which had preceded it.

Reference was also made to the practical results born of experimental methods of investigation. The successful researches of Klein, Pasteur, Klebs, Bollinger, Grawitz, Sanderson, Greenfield, Semmer, Schüller, and many others, were set forth. He ventured to say that, "In the records of human industry it would be impossible to point to work of more promise to the world than these various contributions to the knowledge of disease, and of its cure and prevention; and they are contributions which, from the nature of the case, have come, and could only have come, from the performance of experiments on living animals."

Speaking of the now pending agitation against vivisection, he remarked: "I regret to have had to speak at so much length of the heavy cloud which at present hangs over the study of scientific medicine in England, and which, in my opinion, is likely to be of specially disastrous effect on the progress of preventive medicine. As a very old public servant in that cause, I should indeed grieve to see it brought to a standstill for want of the scientific nurture which, in truth, is its very basis of life; and, speaking publicly of the danger on this occasion, I have hoped that the occasion may give importance to what I say."

He concluded his discourse in the following words:

"And now, gentlemen, from contemplating that cloud, which happily is but local, and which, perhaps, may be but temporary, I gladly turn to skies which have no cloud. If there exist in the social organism any function whatsoever for which development and eventful triumph may be foretold, surely it is that of state medicine. Of the two great factors concerned in it—the two strong powers which within our own time have converged to make it the reality which it is—the growth of science on the one hand, and the growing stress of common humanity on the other, neither one is likely to fail. Of our science it is needless to say that it will grow. To the science of nature, indeed, is allotted that one incomparable human day which knows no sunset. In the pure light of its ever-present daybreak, individual workers will pass away, generations will change, but the studies of nature, and, above all, the gathering of such knowledge as can lessen man's physical difficulties and sufferings, will surely grow from age to age, and, as on Proserpina's sacred tree, one golden fruit will follow another: 'simili frondescet virga metallo.'

"And no less, also, in the other direction, the auguries are wholly for our cause. Popular education is gradually making its way, and it will grow to be a force on our side. Masses of mankind that now have to be humbly pleaded for by others, will then be strong to speak for themselves. Physical interests, now but little understood, will then be within grasp of all men's apprehension. Not only will health be recognized at its true value, and its elementary requirements be regarded, but also the frauds and villanies which are now committed against it will have become intelligible to the common mind; and the workman of the future will strike against being cheated in health as he would now strike against being cheated in wages. As such times come to the world, the science and the profession which care for man as man, will get to be better appreciated than now. And in proportion as an educated people grow to become body-politic, state medicine will be seen to represent that true ideal of government action which sets its standard of success in the 'greatest happiness of the greatest number.'"

## SECTION ON PATHOLOGY.

### ON THE RELATIONS OF MINUTE ORGANISMS TO CERTAIN SPECIFIC DISEASES.

The speaker, Professor Klebs, undertook to answer the question: "Are there specific organized causes of disease?"

A short historical review of the various opinions of mankind as to the origin of disease led, the speaker thought, to the presumption that these causes were specific and organized.

If we now, he said, consider the present state of this question, the three following points of view

present themselves as those from which the subject may be regarded :

I.—We have to inquire whether the lower organisms, which are found in the diseased body, may arise there spontaneously; or whether even they may be regarded as regular constituents of the body.

II.—The morphological relations of these organisms have to be investigated, and their specific nature in the different morbid processes has to be determined.

III.—We have to inquire into their biological relations, their development inside and outside the body, and the conditions under which they are able to penetrate into the body, and there to set up disease.

*First.*—With regard to the first question, that of the possibility of spontaneous generation, the speaker gave a decided negative.

*Second and third.*—There is in microscopic organisms a difference of form corresponding, as a rule, to difference of function. The facts regarding these various lower forms are briefly reviewed.

"Three groups of hyphomycetæ, algæ, and schizomycetæ, have been demonstrated to occur in the animal and human organism in infective diseases. Their significance increases with the increase of their capacity for development in the animal body. This depends partly upon their natural or ordinary conditions of life, but partly also, and that in a very high degree, upon their power of adaptation, which, as Darwin has shown, is a property of all living things, and causes the production of new species with new active functions.

"1. The hyphomycetæ, on account of their needing an abundant supply of oxygen, give rise to but few morbid processes, and these run their course on the surface of the body; and are hence relatively of less importance. It will be sufficient here to refer to the forms: achorion, trichophyton, oïdium, aspergillus, and the diseases produced by them, favus, ringworm, and thrush, to show this peculiarity. Nevertheless, we see that these organisms also (as was proved by the older observations of Hannover and Zenker) may, under certain circumstances, penetrate into the interior of the organs. Grawitz, moreover, has recently shown that their faculty of penetrating into the interior of the organism, and there undergoing further development, depends on their becoming accustomed to nitrogenous food.

"2. Only one of the algæ, viz., leptothrix has as yet acquired any importance as a producer of disease. It gives rise to the formation of concretions, and that not only in the mouth, but also, as I have shown, in the salivary ducts and urinary bladder.

"Another alga, the sarcina of Goodsir, may indeed pass through the organism, without, however, producing in its passage either direct or indirect disturbances. It seems more worthy of note that many schizomycetæ, and especially the group of bacilli, are evidently nearly allied to the algæ in their morphological and vegetative relations—so as to be assigned to this class by several authors, and especially by Cienkowski.

"The schizomycetæ furnish, without doubt, by far the most numerous group of infective diseases. We distinguish within this group two widely different series of forms, which we will speak of as bacilli and cocco-bacteria respectively. The former, which was first exhaustively described by Ferdinand Cohn, and the pathological importance of which, especially in relation to the splenic disease of cattle, was first shown by Koch, consist of threads, in the interior of which permanent or resting-spores are developed. These spores becoming free, are able, under suitable conditions of life, again to develop into threads. The whole development of these organisms, and especially the formation of spores, is completed on the surface of the fluids, and under the influence of an abundant supply of oxygen.

"The number of affections in which these organisms have been found, and which may be to a certain extent produced artificially by the introduction of these organisms into healthy animal bodies, has been largely increased since the discovery of Koch, that the bacteria of splenic fever (anthrax) belong to this group. Under this head must be placed the bacillus malariæ (Klebs and Tommassi-Crudeli), the bacillus typhi abdominalis (Klebs, Ebert), the bacillus typhi exanthematici (Klebs, observations not yet published), the bacillus of hog-cholera (Klein), and, finally, the bacillus leprosus (Neisser). It would exceed the time appointed were I to attempt to describe these forms more minutely. This may, perhaps, be better reserved for discussion and demonstration.

"Alongside of these general infective diseases produced by bacilli, local affections also occur, which indicate the presence of these organisms at the point where disease begins. As an example of these processes, which probably occur in various organs, I would mention gastritis bacillaris, of which I shall show you preparations. In this, we can trace the entrance of the bacilli into the peptic glands, as well as their further distribution in the walls of the stomach, and in the vascular system.

"The second group of the pathogenetic, schizomycetæ I propose to call, with Billroth, cocco-bacteria, because they consist of collections of micrococci, which are capable of transforming themselves into short rods. The former usually form groups united by zoöglœa; by prolongation of the cocci rods are formed, which sprout out, break up by division into chains, and further lead again to the formation of resting masses of cocci. I distinguish, further, in this group, two genera—the microsporina and the monadina; in the former of which the micrococci are collected into spherical lumps, in the latter into layers. The one class is developed in artificial cultivation-fluid, the other on the surface. The former requires a medium poor in oxygen, the latter a medium rich in oxygen, for their development.

"Among the affections produced by microsporina, I reckon especially the septic processes, and also true diphtheria. On the other hand, to the processes produced by monadina belong especially a large series of diseases, which, according to their clinical and anatomical features, may be characterized as inflammatory processes, acute exanthemata, and infective tumors, or leucocytoses. Of inflammatory processes, those belong here which do not generally lead to suppuration, such as rheumatic affections, including the heart, kidney, and liver affections, which accompany this process, sequelæ which, as is well known, lead more especially to formation of connective tissue, and not to suppuration. Here, also, belong croupous pneumonia, the allied disease erysipelas, certain puerperal processes, and finally, parotitis epidemica, or mumps.

"Among the acute exanthemata, the following may, up to the present time, be placed in this group: variola-vaccina, scarlatina, and measles.

"The group of infective tumors is represented by tuberculosis, syphilis, and glanders. Throughout the whole group of cocco-bacteria the demonstra-

tion of organisms in the diseased parts encounters difficulties which vary considerably in the different kinds."

The speaker concluded by describing the methods (now well known) by which the powers of the different organisms are tested.

He also referred to Pasteur's, Chauveau's, and Toussaint's recent experiments.

His conclusion was that the specific communicable diseases are produced by specific organisms.

---

## THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

This exhibition opened July 16th.

One of its most interesting departments was that showing the

### BEDS AND APPARATUS USED BY THE HOSPITALS.

The following description of those is given in the *British Medical Journal:*

In one of the beds we notice, as worthy of attention, a specimen showing the method of applying a "Hodgen's" splint (modified by Bloxam and others) to a fractured thigh. The limb is swung in a wire-cradle, with flannel-understraps, and the long splint, with its elaborate bandages, is entirely dispensed with. In a compound fracture, the wound can be got at without disturbing the limb; and the only drawback is, that a certain amount of lateral movement is permitted between the fractured ends of the bone. In the next bed is seen, applied to the head, an ingenious apparatus (of German invention) for applying cold to any part of the body; a current of iced water is kept constantly circulating through a system of tubes, made of lead, sufficiently firm to resist the weight of the body, and yet small and soft enough, it is said, to cause no inconvenience to the patient. This apparatus is much used by Mr. Bryant, and may be seen, in various sizes and shapes, in the surgical-instrument department of this Section.

A very neat and convenient cot is shown; and on the opposite side will be found a tracheotomy cot and tent, which is as well suited for its purpose as any other exhibited; though this is, unfortunately, by no means high praise. In this cot we notice Mr. Golding-Bird's "trachea-dilator," made for him by Messrs. Millikin & Down. This instrument consists of two fenestrated blades, which are designed to be introduced into the tracheal wound, and then separated by a screw-action. We have lately had an opportunity of testing this instrument, and can testify to the ease with which it can be introduced, and to the effectual manner in which it keeps open the wound in the trachea, and gives free exit to mucus and membrane. As might be anticipated, the pressure exerted on the two edges of the tracheal wound quickly leads to ulceration of the mucous membrane; and for this reason the use of the instrument must, we believe, be limited to the first twenty-four hours. At the end of that time, when hemorrhage has ceased, and most of the membrane about the cords has been cleared away, its place may be well supplied by one of Mr. Morrant Baker's india-rubber tubes, which are shown in use in a tracheotomy tent exhibited by St. Bartholomew's. This tent is very neat and pretty, and consists entirely of washable materials. It, however, strikes us as rather small, and by no means perfection; indeed, we hope that one of the salutary results of the exhibition may be to stimulate inventors to design a really suitable tent for this purpose.

Among the other specimens shown by St. Bartholomew's Hospital, is the apparatus for fractured patella designed by Mr. Manning, as also another method of treating this lesion designed by Mr. Stephenson, a former house-surgeon of the hospital, in which the fragments are retained in position by two broad elastic bands attached to a subjacent wooden-cradle. We also notice the contrivance of the late Mr. Callender (commendable for its simplicity) for making pressure on a femoral artery. Fracture of the femur is treated by a long outside (Liston) splint, and extension is made by an ingenious little apparatus, designed, we learn, by a former house-surgeon, Mr. Sankey, and adopted also by the Children's Hospital (Great Ormond street). This latter hospital exhibits a cot illustrating the treatment of hip-joint disease in general use there. The diseased limb is bandaged to a splint, which is supported beneath by an apparatus on the principle of a book-rest, and extension is made as above stated; a long outside splint is applied to the sound limb, and the head only of the little patient is supported on a square pillow: the child is retained in the recumbent position by the so-called "Queen's square armlets," a method also made use of in the bed shown by St. Mary's, where it is adapted to a "patient," on whom is also demonstrated the method of treating cervical caries by a leathern collar moulded (by Spratt, of Brook street) to the neck. Leathern splints made by the same firm are also shown in the St. Mary's cot, adapted to the treatment of strumous disease of the knee. The collar for cervical caries is supplemented by sand-bags, so arranged as to prevent rotation of the head.

The Middlesex Hospital shows the old-fashioned, but very useful, if rather clumsy, De Morgan's splint for the treatment of morbus coxæ; and a most convenient apparatus, first used, we believe, by Dr. Cayley, for bathing a fever patient with the least possible disturbance: a hammock slung from a movable gallows receives the patient, who is then raised from his bed by pullies, carried by a traveller until he is suspended over a bath placed beside the bed, and finally lowered into the bath by a reversed action of the pulleys.

The exhibit of King's College Hospital shows the various apparatus used in the antiseptic treatment of wounds, though we may remark, by the way, that the dressings are only placed in the basket shown when about to be used. It is, we think, unfortunate that one of the tin boxes ordinarily in use for storing the dressings is not also exhibited. We are sorry to find fault, but the tracheotomy-tent shown by this hospital, with its heavy flannel curtains and clumsy frame, seems to us singularly unsuited for its purpose, and unworthy of the institution from which it emanates. Neither is the bed shown by University College Hospital worthy of the reputation of that school; we may notice, however, the method of treating Colles' fracture by Carr's splints.

We have nothing but praise for the beds shown by St. Thomas's Hospital. That one which illustrates the adoption of plaster-of-Paris splints, as recently recommended by Mr. Croft, is particularly worthy of careful study, and seems to us the perfection of neatness and simplicity. A cot is also shown by this hospital, which demonstrates a most convenient method of treating hip-joint disease.

We must also strongly recommend to the careful study of our readers the apparatus shown by Charing Cross Hospital. Two beds show the fenestrated splints designed by Mr. Barwell, which are

so simple that they can be made by the ordinary engineer of the hospital. The one designed for excision of the knee strikes us as particularly admirable; the back-splint, with broad plates of soft iron moulded to the thigh and calf, reaches from the fold of the nates almost to the knee; the anterior splint consists of three plates moulded to the thigh, leg, and foot, connected together by light iron rods; the heel is left entirely free, and the fenestrum over the knee is sufficiently wide to permit of the easy application of an antiseptic dressing without at all disturbing the splints, which are from the first firmly fixed to the limb by plaster bandages. Another bed, arranged by Mr. Bloxam, shows a "Hodgen's" apparatus, already referred to, as modified by him, and a similar arrangement by which the use of bandages in the treatment of fractured tibia can be entirely dispensed with. The London Hospital, the New Marylebone Infirmary, the Royal Free Hospital, and the Westminster Hospital show beds which are of interest, but which contain no special novelties; and St. George's Hospital also exhibits some apparatus, but of a rather antiquated type.

Lastly, we may notice the bed shown by the hospitals of the army and navy, which illustrates the first treatment of wounds and fractures, and is a marvel of ingenuity. Esmarch's triangular bandages are used throughout, and we should especially direct attention to the treatment of fractured thigh. A rifle forms a long outside splint, a waist-belt supplies the place of a body-bandage, triangular bandages fix the impromptu splint to the thigh and ankle, and a third bandage is used as a perineal band; the same bandages serve to fix two bayonets to the arms, where they act as excellent splints; and a wound of the hand is also dressed with this bandage. If any fault can be found, it must be with the tourniquet in use, which we have heard described by a good authority as the worst in existence.

## UNVEILING OF THE HARVEY STATUE AT FOLKESTONE.

The statue of William Harvey, the discoverer of the circulation of the blood, was unveiled before a numerous company on Saturday, August 6th. The ceremony took place at Folkestone, the birthplace of the illustrious scientist. It is not necessary here to refer to the brilliant career of Harvey, for the essential facts of his life, although it was spent nearly three hundred years ago, are familiar to the profession.

The statue now erected at Folkestone is a bronze figure, eight feet high, sculptured by the artist Albert Bruce Joy. It is placed on a granite pedestal, adjacent to Castle Hill avenue, facing the sea, and not far from the site of the house which was Harvey's birthplace. For the unveiling ceremonies a special train had been granted to bring down the guests of the Folkestone mayor and corporation from London. They comprised Sir James Paget, President of the International Medical Congress this year, Professor Richard Owen, C.B., of the British Museum, Professor Albanese (Palermo), Dr. Astley, Professor Bamberger (Vienna), Professor W. Braune, Professor Donaldson, Dr. Fornoni, Professor Gamgee, Mr. Barnard Holt, Sir Henry Hunt, Professor W. Littlejohn, Professor Macalister, Professor Moore, Professor Panum, Professor Quinlan, Dr. Owen Rees, Mr. Ernest Hart, Professor Rutherford, Dr. Ranking, and Dr. Sieveking. The Mayor of Folkestone, Mr. J. B. Tolputt, with the Aldermen and Town Councilmen in their robes, and with Sir Edward Watkin and other gentlemen, met the train at Shorncliffe station, and a number of carriages were ready to convey the visitors to the enclosed space and raised platform around the Harvey statue. Dr. Eastes there opened the proceedings, and spoke of the merits of William Harvey and his services to mankind, as one of the greatest discoverers in anatomy and physiology. He then called upon Professor Owen, one of the most eminent comparative anatomists and physiologists in the modern scientific world, to unveil the statue and present it, on behalf of the subscribers, to the Mayor and Corporation of the town.

Professor Owen, in his address before unveiling the statue, explained how the methods and results of Harvey's discovery had not only laid the foundation of all progress in physiology, but had been the basis of modern scientific medicine and surgery, and consequently, the source of countless blessings to suffering humanity. From this point Professor Owen passed into a disquisition on the experiments and discoveries of Harvey and his follower, Hunter, showing the value of vivisection as the helpmate of surgical research and discovery, and without which we should still be in the dark ages of science as regarded the healing profession. In conclusion, he remarked that it seemed to him to be a public duty germane to the memory of the "great vivisector," to oppose a now threatened appeal to the Legislature totally to prohibit such experiments as those to which mankind was indebted for Harvey's and Hunter's great discoveries. He was prepared to prove, on all fitting occasions, the mode and degree in which vivisection imparted the power of diminishing and removing the sufferings of our fellow men. The learned Professor concluded by presenting, on behalf of the committee and subscribers, the memorial to the Mayor and Corporation of Folkestone.

Canon Jennings offered a prayer, and after a few words from Dr. Bowles to his medical brethren of the town, the company adjourned to the Town Hall, where luncheon was provided under the presidency of the Mayor. Prosessor Owen proposed "The memory of Harvey," which was drunk in silence. Sir Edward Watkin proposed the health of Professor Owen, to which that gentleman responded. The Mayor then presented Professor Owen with a complete set of Harvey's works. Dr. Erichsen proposed the health of Sir George Burrows, Dr. Simon, Dr. Rees, Dr. Eastes, and Mr. W. G. S. Harrison, who have been connected with the memorial fund. This terminated the ceremonies, and the party soon broke up to return to London by a special train.

Hints from the Homœopathic Pharmacopœia.—Dr. Piffard, in his treatise on "The Materia Medica and Therapeutics of the Skin," gives a number of remedies not confined to the U. S Pharmacopœia.

Thus, a favorite remedy for early syphilis is the hydrargyrum oxidum nigrum Hahnemanni, in a state of trituration, in doses of $\frac{1}{3}$ to $\frac{1}{36}$ of a grain. The same authority highly recommends the administration of other remedies, such as corrosive sublimate, cyanide of mercury, arsenious acid, etc., in the form of triturations, as being more soluble.

In acute eczema, Dr. Piffard believes that rhus toxicodendron will cut short the attack if taken at the beginning; and he adds that $\frac{1}{100}$ of a drop of a good tincture is not too much to begin with.

# THE MEDICAL RECORD:

## A Weekly Journal of Medicine and Surgery.

New York, September 3, 1881.

## THE INTERNATIONAL MEDICAL CONGRESS.

In this week's issue we conclude our report of the London session of the International Medical Congress. Now that the complete work of the various sections, as well as the general addresses, are before us, we can better estimate the wide scope and far-reaching significance of this, the seventh of the great international medical gatherings. And most certainly are we now justified in the repetition of a former statement, that never before has so important, so extensive, and withal so satisfactory a meeting of scientific physicians been witnessed by the medical fraternity or the world at large.

The truly cosmopolitan character of medical science never received a nobler vindication. The *Lancet*, commenting upon this theme, aptly points out the power of science "to overcome the strong barriers set up by history, race, language, and creed." It further remarks: "To find men of the highest eminence and worth, hurrying from all parts of the civilized world to meet in Congress for a few short days, and be as of one great family, calls up a vision so often pictured by reformers—the true solidarity of nations. Amid the many jealousies of country and of creed, it is of no small value to find that there is a platform on which all are glad to meet for one common purpose, however much they may vary in education, or political and social advancement."

On almost every conceivable topic of contemporaneous interest to the profession, and on several points of highest importance to mankind in general, we have been given the matured opinions and well-considered judgments of those best qualified for their expression. Indeed, the selection of the speakers for the general assemblies has been a most judicious one, and reflects the highest credit upon the gentlemen in charge of the matter. The sectional addresses were, perhaps, occasionally ponderous or devoid of novelty, and often lacking in that broader interest which characterized the general discourses. But that is an inherent drawback of specialism, and cannot be construed into a reproach to the Congress.

Moreover, for the first time in the history of these medical reunions, has a truly international gathering been successfully arranged. Of course the English-speaking element was the predominant one, but all civilized nations had sent representative men. Many of these were of undisputed eminence in their respective countries, and not a few enjoyed a world-wide fame. Briefly told, then, the leading features of this immense medical gathering were its truly international character, the practical turn given to the large amount of work accomplished, the exceptional value of many of the addresses, and, we may add, the perfect demonstration it gave of the meaning of British hospitality. A happy and harmonious blending of earnest business with pleasure was indeed noticeable throughout the week. We feel assured that the liberal hospitality uniformly extended to foreign delegates and visitors, will be warmly appreciated, and will long remain with them a happy and grateful recollection of the past Congress.

Of course our account of the numerous festivities "that formed so graceful a feature of the week" has of necessity been rather brief; nevertheless, it should suffice to indicate the justice of the foregoing remarks concerning British hospitality. The visits to London's great hospitals doubtless afforded much satisfaction to many foreign delegates. In this, as in many other respects, it would indeed be difficult to estimate the indirect fruit which this Congress will bear, quite apart from the direct stimulus which it must needs impart to medical progress.

It was, of course, quite inevitable that the subject of germs and their relation to disease should have been approached. Nor can the opinions so clearly set forth by Pasteur, the avowed champion of modern experiments relating to disease-germs, in the least surprise us. We can hardly share the sanguine views he holds concerning the infinite power of preventive medicine, but we gladly recognize the value and importance of past labors and continued researches in this field.

What did surprise us, however, was the unmistakable hesitancy with which Lister met the cool but determined opposition of Keith and others. This opposition to the details of Listerism was based on facts and figures, the eloquence of which, perhaps, somewhat upset Mr. Lister's argumentative purpose. At any rate we are pleased to observe that the originator of an orthodox and dogmatic system of wound-treatment has expressed, or intimated, his readiness to abandon one detail, at least, of Listerism which has been hitherto pronounced its most

essential and characteristic feature, viz.: the spray. The practical outcome of this admission on the part of Lister will doubtless soon be made conspicuous by a widely re-echoing cry of "*Fort mit dem spray!*"

The brilliant, sometimes passionate, yet always philosophical and logical pleading of Virchow, in behalf of untrammelled liberties of pathological experimentation, and the endorsement of his views by the whole Congress, should be a convincing argument to all the world of the paramount justice and importance of vivisection. It will be sure, moreover, to dismay the champions of anti-vivisection and their followers.

Simon's address was a masterpiece in its way, and will remain a lasting monument to his broad intelligence and noble humanity.

The power and eloquence of Paget's presidential address, the warm sympathy it expressed with human efforts, the cheering and hopeful view it took of medical progress, combined to shed the grateful rays of a confiding optimism on subjects which often quite naturally lead to direst pessimism.

In Volkmann's address we are treated to an able review of past surgery on the Continent, together with the accurate description of the great and favorable changes which antiseptic methods of wound-treatment have wrought in the results of operations, mainly of German hospitals and clinics. The speaker dwelt at some length on the manner in which operative surgery had extended, and was still enlarging its legitimate domain. He opened up a proud and brilliant vista of past accomplishments, and foreshadowed a future of glorious achievement in this department of the healing art.

Dr. Billings' address seems to have been an agreeable surprise to our transatlantic brethren, who are not in the habit of listening to American raciness, humor, and rhetoric. His speech, although largely statistical, was so alive with sallies, hints, and terse expressions, that it kept his listeners awake with unfeigned attention till his last word was uttered.

The interest which attaches to M. Raynaud's valuable address on "Scepticism in Medicine," was tempered with melancholy regret at his untimely and unexpected death. His friend, Dr. Férêol, ably read the appeal implied in his departed colleague's words—an appeal mainly directed against the unfortunate tendency to nihilism in medicine. Let us hope that his earnest admonition to think more of what we do know than what we do not know, may be heeded by the generations which will succeed him and his era.

Huxley's address was, in all respects, a masterly production. We cannot withhold our admiration from a mind so keen, so vast, and so versatile, that even when it discusses subjects without the realm of its special pursuits, we, the true specialists of that field, are yet instructed, pleased, and almost awed. Huxley laid some stress on the fact that Harvey, to whom he paid a glowing tribute, should be known rather as the first demonstrator of the essential facts of circulation, than as the actual discoverer of its existence. Medical empiricism came in for a liberal share of criticism, mitigated, however, by the expression of the fond hope that strict science and true practice might soon go hand in hand toward the common goal of the improvement of the human race.

In taking leave of the London session of the International Medical Congress, we may be permitted to indulge the hope that its future meetings, if they do not excel, will at least equal the one just past in magnitude, brilliancy, the practical value of its manifold work, and the uniform success of its numerous entertainments.

---

### THE PRESIDENT.

After our last writing the condition of the President continued to grow worse, until the 26th ult. At that time his pulse occasionally reached 120. His mind at times wandered. The secretion from the wound was unhealthy in appearance, and the parotid gland, which had suppurated, showed no signs of improvement. The President had lost, it was estimated, eighty pounds of flesh, which is very nearly two-fifths of his body weight.

The patient's strength seemed failing. The fever did not rise higher than usual, nor was the respiration much increased. But all the symptoms were bad, with the exception that the stomach retained and apparently digested nourishment.

The hopes of recovery, which were nearly abandoned at that time, have since been revived. The patient, on the 27th, began to show more favorable symptoms. The pulse became slower and stronger, the wound and the parotid abscess presented a better appearance, and the patient's mind became clearer. More nourishment was called for and taken.

During the critical period, nourishing and stimulating enemata were given; but these have now been discontinued, and, at date of writing, the inflammation of the parotid appears to be on the decline.

The later symptoms of the President have shown very clear evidence of septic infection; the consequent depraved condition of the blood, as we mentioned in our last issue, allows of new complications to be expected every day. There is yet every reason to fear therefore that a final collapse may any day be announced. Still, some hope of recovery can be reasonably entertained.

The lungs are now being carefully watched. It certainly shows a marvellous strength of constitution that the President has lain helplessly in bed for

eight weeks with, as we are informed, no pulmonary complication at all.

There has been much vague talk about the patient's suffering from pyæmia. Certainly in no proper sense of the word has he had that complication. The term pyæmia, as generally used, is a nosological blunder, as was pointed out by Virchow, and it has been wisely discarded, or relegated to only a peculiar form of infective fever, by later writers.

Attacks continue to be made on the medical attendants by some of the daily papers. These attacks are foolish and sensational. The confidence in the skill of the President's advisers should be, and still is, maintained by those competent to judge of it. It is most unreasonable to suppose that the numerous suggestions which are put forward by medical men and laymen have not been intelligently considered by those in charge of the patient.

It is fair, however, to inform the medical attendants what the criticisms among medical men are, and what the profession will eventually call upon those responsible for the President to explain.

It will not be asked why they did not at first probe the wound and at once remove the bullet. The course of treatment adopted was in accordance with the best surgical practice, and it cannot be criticised. But it will be asked why the patient was kept in a house where several attendants had to leave on account of malaria?

Why the wound was not probed and the bullet searched for after the wound had granulated along its course?

Why they announced for so many days, in vague and rose-colored bulletins, that the "symptoms were somewhat more favorable," when the patient was losing over a pound in weight every day, and was, as it seemed later, steadily failing in strength?

Whether the enormous and rapid loss of flesh, with so little fever to produce it, could not have been in any way lessened, and whether the excretions were chemically examined to determine, if possible, the exact cause of this loss?

We put these questions because they are being asked by medical men, and will continue to be. We have no doubt that they can be satisfactorily answered.

---

### ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

The British Medical Association held its annual meeting at Ryde, Isle of Wight, on August 9th, 10th, 11th, and 12th. Coming, as it did, immediately after the International Medical Congress, its work was naturally much overshadowed by that of the previous gathering. Nevertheless, as the British Association is the largest medical organization in the world, its annual sessions cannot fail to furnish something of importance and interest. In addition to this, the meeting was held in a beautiful town, with many rural attractions about it, so that not a few stragglers from the London Congress were found there. There was, consequently, a good attendance, and some excellent work done.

The discourse of the President, which we present in part elsewhere, was interesting as a literary effort, though rather commonplace on the whole. Dr. Bristowe's address, however, upon homœopathy deserves careful reading, especially its latter portion. After showing, with much more knowledge and candor than is generally exhibited, its absolute fallaciousness as a system of medicine, he yet advocates charity and liberality toward those practising it. We shall recur to his conclusions on some later occasion.

The report of the treasurer shows that there is a balance of $50,000 in the treasury. We may well, in America, think with envy of the amount of scientific work which such a sum of money might secure.

The most important of the annual reports was that of the committee on organizing a system of cumulative observation. This committee, in response to a suggestion made by Dr. Humphreys a year ago, reported a plan for securing an extended series of clinical observations upon various subjects. It suggested a number of subjects to be thus studied, and it would have a secretary appointed at a salary of one thousand dollars a year, who should travel about to the different sectional meetings, and thus obtain the results of the observations of many individuals upon matters selected for this mode of study. It can easily be seen what important results may be secured in this way.

---

Eucalyptol *versus* Carbolic Acid.—Eucalyptol has been proposed by Lister as a safe and efficient substitute for carbolic acid in surgical dressings. This substitution is also warmly recommended by Mr. C. Roberts, of London *(British Medical Journal)*, who has used it with the best results.

The State Medical Society of Nebraska has published the proceedings of its ninth, tenth, eleventh, and twelfth annual sessions. Of these meetings the first three are remarkable for the paucity of reports on the part of the various sections. At the tenth the following unique resolution was introduced:

"*Resolved*, That the Nebraska State Medical Society deprecates the *abuse* of alcohol in any manner *except for medicinal purposes*, believing it to be detrimental to health, degrading to nature," etc.

In view, however, of certain facts, among others "that it would be a committal of the society, after having accepted of the champagne tendered at the previous evening," the motion to adopt was withdrawn, and we are left to infer that the Nebraska State Medical Society sanctions the *abuse* of alcohol, even for medicinal purposes. A number of papers were read at the twelfth session. Dr. v. Mansfelde presenting "Sex Production" and "The Ovum in its Relations to the Laws of Evolution."

# Reviews and Notices of Books.

A Treatise on Diseases of the Joints. By Richard Barwell, F.R.C.S., Senior Surgeon and Lecturer on Surgery, Charing Cross Hospital. Second Edition. New York: William Wood & Company. 1881.

This volume of 463 pages forms a valuable addition to Wood's Library of Standard Medical Authors. Mr. Barwell has entirely rewritten his book, and he tells us in his preface that: "in its present form the treatise contains but a few words here and there of the first edition." Nevertheless, upon examination it appears that the book is not in all respects as modern as it should be. This is especially noticeable in the first chapter, which deals with the pathological anatomy of joints. The author makes a fundamental distinction between diseases beginning in the synovial membrane and such which commence in the bones. Practically, however, it is to be borne in mind that in most advanced cases it is not possible to discover the precise origin of the disease. Hence, we cannot agree with Barwell in believing such a primary distinction must underlie successful treatment. Still, an accurate and scientific diagnosis is always desirable, even if it be not invariably possible.

The different forms of synovitis, arthritis, and ostitis, the affections of the sheaths and bursæ, hysteric pseudo-disease of joints, genu varum and valgum are each in turn satisfactorily dealt with. A fact which enhances the practical utility of the volume, consists of the copious supply of typical cases of the various diseases described, many of which also illustrate the good results of the author's methods of treatment. Most of Barwell's therapeutic measures are the approved ones of the profession. Perhaps this circumstance may be interpreted as indicating a lack of originality on the part of the author, but we prefer to see in it only a sign of judiciousness in the choice of recommendable modes of treatment. Taken all in all the volume is likely to be found serviceable both by surgeons and that large class of general practitioners who treat surgical diseases.

The Sympathetic Nerve: its Relations to Disease. By C. V. Chapin, M.D., House Physician, Bellevue Hospital. Providence: J. A. & R. A. Reid, Printers. 1881.

This is the Fiske Fund Prize Essay, and though entirely wanting in evidence of original research, it nevertheless bespeaks the author's capability as a compiler. Above all things this essay possesses the merit of brevity, in fact this is sometimes carried to excess. Certainly the writer's style could have been much improved by a little additional expansiveness here and there. After a brief account of the main facts regarding the anatomy and physiology of the sympathetic system, the author takes up the consideration of diseases involving the sympathetic nerve. It seems to us that in an essay like this, therapeutical indications had best been altogether omitted, rather than given the very meagre and unsatisfactory representation here found. Although the writer has diligently collected the main facts pertaining to his subject, he has not gathered all the information necessary for a complete résumé of our knowledge on the relation of the sympathetic to disease. One very notable omission is the author's failure to even mention the careful researches of Da Costa and Longstreth on the state of the ganglionic centres in Bright's disease. The author's index is also a very poor one, and might have been entirely omitted without detriment to the usefulness of his little compilation.

Manual for the Physiological Laboratory. By Vincent Harris, M.D., London, M.R.C.P., Demonstrator of Physiology at St. Bartholomew's Hospital, etc., and D'Arcy Power, B.A., Assistant Demonstrator of Physiology at St. Bartholomew's Hospital, etc. 12mo, pp. 124. New York: W. Wood & Co. 1881.

The present little volume, although of modest pretensions and narrow in scope, is a reliable guide-book for the student who desires to learn something of the rudiments of histological methods and histochemistry. There hardly appears any necessity, however, for inserting the very incomplete account of the minute structure of the various organs and tissues. The practical value of this student's manual might have been considerably enhanced by more attention to methods of preparation, and an entire omission of histological details. In its present shape the work before us will doubtless be welcomed by the students attending courses at St. Bartholomew's Hospital, but it can scarcely hope to appeal to a wider circle of readers. We are already supplied with plenty of similar, and, for the most part, more satisfactory books.

Surgical Principles and Minor Surgery. By J. G. Gilchrist, M.D., formerly Lecturer on Surgery in the Homœopathic Medical College of the University of Michigan, etc. Chicago: Duncan Brothers. 1881.

This volume is intended to be the initial one of a series of four or five on surgical topics, which Dr. Gilchrist intends to prepare. It is meant to supply the student with a reliable guide during the first year of his medical pursuits. We fear, however, that Gilchrist's way of looking at medical training is a very superficial one. He puts the cart before the horse, as it were, in endeavoring to teach the student mechanical wound-appliances in an utterly routine manner, and without the faintest preliminary notion of surgical diseases. Besides we have little faith in works of this kind, as they can never equal the practical demonstration of surgical methods and manipulations upon the persons of the patients themselves. A student will be apt to learn more from the personal application of a single bandage, under proper supervision, than if he read ten books like the one before us. Dr. Gilchrist's book, however, is about as good as the general run of works on minor surgery, even if many of its truly homœopathic recommendations will seem rather absurd to any one who is *au fait* with modern surgical principles.

Medical Electricity: A Practical Treatise on the Applications of Electricity to Medicine and Surgery. By Roberts Bartholow, A.M., M.D., LL.D., Professor of Materia Medica and General Therapeutics in the Jefferson Medical College of Philadelphia, etc. 8vo, pp. 262. Philadelphia: Henry C. Lea's Son & Co. 1881.

Dr. Bartholow has attempted to write a practical book for persons quite unfamiliar with medical electrology. In this he has undoubtedly succeeded. He is candid enough, however, and sufficiently mod-

est to explain to the reader that "no claim is made on the ground of pure science." We consider the work a fair and accurate résumé of the present condition of our knowledge concerning the applicability of electricity to the human organism for diagnostic and remedial purposes; still the book is calculated to be of service to the student rather than the practitioner. The latter may be supposed to possess some familiarity with electrical manipulations, and will really find but a limited amount of instruction in the pages of our prolific author's latest production.

But even the student should not too implicitly rely on the positive assurance of the value of electricity in the numerous diseases for which it has been recommended. He should remember that the present book emanates from the pen of an optimist in all matters therapeutical. No one of course would to-day wish to dispute the great utility of electricity in some conditions of organic disease or functional disturbance. But one rises from the perusal of Dr. Bartholow's treatise with the conviction that the author expects rather more from electricity than would seem to be justified from well-authenticated facts. As he himself justly remarks, we all know "that extraordinary results have been achieved by agencies which simply impressed the imagination." The danger of writing on medical topics in a spirit of undue enthusiasm, lies in the fact that the first inevitable disappointment is too apt to fatally touch the tyro's faith. And thus scepticism or utter nihilism may be the harmful result of exciting unjustifiable expectations in the inexperienced mind of the student or young practitioner.

THE PRINCIPLES OF MYODYNAMICS. By J. S. WIGHT, M.D. New York: Bermingham & Co. 1881.

THE author presents, in a compact form, an analysis of the principles of myodynamics, or the forces of muscles and their effects. The subject is subdivided into Myostatics, which treats of muscular forces in equilibrium, and Myokinetics, which treats of muscular forces when they are moving some other force. These subjects, of course, involve a full discussion of the lever and of the parallelogram of forces. The application of these physical laws to the phenomena of muscular contraction and the various movements of the limbs, make up the latter and larger part of the book.

The subject is explained clearly, though, if anything, too briefly. It is very fully illustrated.

We welcome any work which tends to give more exactness to medical and surgical science. Such is undoubtedly the tendency of this work. And we quite agree with the author in his belief, that the better a surgeon understands the principles of myodynamics, the better he can treat fractures, dislocations, and deformities.

THE BROMIDES IN TRAVELLING.—Dr. E. J. Tilt (*British Medical Journal*) says that he has often been able to make travelling comfortable, especially to women, by giving them twenty-five to thirty grains of bromide of potassium on going to bed at night. If the weariness and distress arising from long travelling be great, the same dose should be repeated in the morning.

Very similar directions to these are given in Beard's much criticised book on sea-sickness.

# Reports of Societies.

## BRITISH MEDICAL ASSOCIATION.

*Forty-ninth Annual Meeting, held at Ryde, Isle of Wight, August* 9, 10, 11 *and* 12, 1881.

ADDRESS OF THE PRESIDENT, BENJAMIN BARROW, F.R.C.S.

AFTER referring to the deaths that had occurred among members of the association during the past year, the speaker enumerated the different objects of interest to be found in the vicinity, and welcomed the profession to the island.

He then said that he had chosen for the subject of his discourse the following questions, which he should try to answer affirmatively:

"Are not the duties of medical men, the honest and honorable performance of them, such as to command for our profession an equality with, if not pre-eminence above, every other? If the duties are so performed, are we not entitled to the very highest position in the estimation of the public? Has the profession been so esteemed; if not, what are the causes of such defection?

"I am," he said. "led to this topic, too boldly, perhaps, by an experience of half a century; an experience which induces me to think—having no longer any personal interest in the opinion of the public, save that of my never-dying wish for your welfare, collectively and individually—that I might not uselessly speak to you from the fulness of my heart.

"I propose to consider my observations under two heads, the secular and the sacred; I shall deal with the secular first—not that I consider it of primary importance, but because it leads up to the other. The secular I shall treat of under two heads: first, the antiquity of our profession; and, secondly, the work done by men of the past, and that being done by men of the present."

The speaker then gave a rapid review of the history of medicine and the work done by its masters. He quoted the first poetic praise of the surgeon by Homer, in the words of Eurypylus to Patroclus:

> "But thou, Patroclus, act a friendly part,
> Lead to my ships and draw the deadly dart;
> With lukewarm water wash the gore away,
> With healing balms the raging smart allay;
> Such as sage Chiron, sire of Pharmacy,
> Once taught Achilles, and Achilles thee.
> Of two famed surgeons, Podalirius stands
> This hour surrounded by the Trojan bands,
> And great Machaon wounded in his tent,
> Now wants that succor which so oft he lent."

He ended with the tribute to Jenner inscribed upon his monument at Berkeley:

> "Within this tomb hath found a resting-place
> The great physician of the human race—
> Immortal Jenner; whose gigantic mind
> Brought life and health to more than half mankind.
> Let rescued infancy his worth proclaim,
> And lisp out blessings on his honored name;
> And radiant beauty drop her saddest tear,
> For beauty's truest, trustiest friend lies here."

The speaker then gave his opinions upon the various mooted topics of vaccination, vivisection, temperance, etc.

Regarding temperance, he advocated the use of liquors in medicine. He would have vaccination compulsory, and even more strictly applied than it now is. He believed in the morality and usefulness of the Contagious Diseases Acts, and in the value of

vivisection. He thought it wrong and unjust to compel medical men to report cases of infectious disease—the obligation should be put on the householder. With regard to lady-doctors and lady-nurses, the distinguished orator was very conservative. He did not believe in either of them. He said: "I am not over-squeamish, nor am I over-sensitive; but I almost shudder when I hear of things that ladies now do, or attempt to do. May not this work, the performance of the duties of which entail long watchings, much exhaustion of mind and body—may it not, will it not, so change that fine organization, that sensitive nature of women, so as to render her dead to those higher feelings of love and sympathy which now make our homes so happy, so blessed? Will not the strain upon the delicately-nurtured female have a prejudicial effect upon the babe still unborn? Will not England's glory fade without its modest, sympathizing women, and its race of stalwart youths and blooming maidens? You now, gentlemen, know my views as to the propriety of ladies becoming doctors or nurses."

The speaker then discussed the sacred side of the physician's work. He showed that many of our great physicians were infused with religious sentiment. He quoted Galen's views, the result of his long anatomical and physiological studies: "In writing these books, I compose a true and real hymn to that awful Being who made us all; and, in my opinion, true religion consists not so much in costly sacrifices and fragrant perfumes offered upon His altars, as in a thorough conviction, impressed upon our minds, and an endeavor to produce a similar impression upon the minds of others, of His unerring wisdom, His resistless power, and His all-diffusive goodness. For His having arranged everything in that order and disposition which are best calculated for its preservation and continuation, and His having condescended to distribute His favors to all His works, is a manifest proof of His goodness, which calls loudly for our hymns and praises. His having found the means necessary for the establishment and preservation of this beautiful order and disposition, is as incontestable a proof of His wisdom as His having done whatever he pleased is of His omnipotence."

The President, in conclusion, said that he believed his questions first propounded could all be answered in the affirmative, and "that our profession merits the highest consideration from the world at large, and that it stands upon the topmost pinnacle of fame."

---

## ADDRESS IN MEDICINE.

### By John Syer Bristowe, M.D.

The speaker began by alluding to the position of medicine among the sciences. He thought that those who criticised its work did not understand how vastly more difficult and complicated its study is than that of the exact sciences. As regards the future possibilities of medicine, he took no Utopian views. We shall never find specifics for every disease, or make mortal life immortal. But we can expect vast improvement over its present condition. He then took up the subject of

#### HOMŒOPATHY.

He sketched the life of Hahnemann, and then gave an interesting account of the Organon. "This Organon," he said, "is a remarkable work, very interesting also, and very entertaining; for it not only comprises the quintessence of his labors, but reveals the character of the man, as in a mirror, with all his strength and all his weakness, all his wisdom and all his folly.

"Hahnemann was a physician who had a supreme contempt for pathology, and, on the whole, for etiology. He inveighs over and over again against the absurdity of those who endeavor to discover, in morbid phenomena within the body, an explanation of the symptoms which persons who are ill present. He says: 'We may well conceive that every malady implies a change in the interior of the organism, but this change can only be surmised obscurely and fallaciously from the symptoms; it can never be recognized infallibly in its complete reality. The invisible changes wrought by the malady within the organism, and the changes perceptible to our senses (that is to say, the sum of the symptoms), together form a complete image of the malady; but that image is only visible in its entirety to the eye of the Creator. It is the totality of the symptoms which alone constitutes the part of it accessible to the doctor; but it is likewise in the totality of the symptoms that we find everything that it is needful to know in order to cure.' To Hahnemann it is a matter of no moment whether ascites depends on cirrhosis of the liver, or tubercle of the peritoneum; whether an attack of constipation and colic arises from lead-poisoning or from a cancerous stricture; whether a paralytic seizure is the outcome of hysteria, or is due to some material lesion of the brain. In each case, to him, what is the condition of things within is an idle speculation; the symptoms of which the patient complains comprise all that the medical man need know; and to treat these according to the true laws of homœopathy is to cure the disease. But he goes further: for, not satisfied with stigmatizing all pathological investigations as mere pedantry and foolishness, he actually objects to all attempts on the part of systematic writers and practical physicians to distinguish and classify diseases.

"Hahnemann rejected therefore etiology as being of any use to the physician; he rejected pathology, or more especially, morbid anatomy, and nosology.

"Hahnemann's views of the nature of disease were doubtless subservient to his views of the curative operation of drugs. And it is on his therapeutical views, if on anything, that his reputation must depend.

"Stated generally, his views are as follows: The innumerable diseases which afflict mankind, and which arise out of natural causes, consist, for the purposes of the physician, of groups of symptoms; the innumerable remedial agents which exist in nature, locked up in the animal and vegetable kingdoms, and in the inorganic world, are themselves the causes of a parallel series of artificial diseases, which again, for the purpose of the therapeutist, consists of groups of symptoms; in order to cure any natural disease that may come before us, it is necessary to administer that particular remedial agent which is capable of producing identical symptoms with it, and of course this must be given in a suitable dose, for, if in too minute a dose, it leaves a residuum of the original disease uncured: if in too large a dose, it cures the disease, but induces after-effects of its own; and, further, inasmuch as we are not yet acquainted with the specific virtues of all remedies, and inasmuch, therefore, as for a large number of diseases the most suitable homœopathic remedy has not yet been discovered, we must in

such a case select a remedy the effect of which approximates to the symptoms of the disease, by which means we shall cure a certain area, so to speak, of the primary disease, but we shall leave a new disease behind, compounded of the as yet uncured symptoms of the old disease, and the supernumerary symptoms due to the drug itself, which new disease must be treated *de novo* on homœopathic principles. How curious, how ingenious, how interesting the whole thing is! How excellent, if true! And has it not the simplicity of truth in it? The entire range of diseases, the entire range of therapeutics, converted into Chinese puzzles; the phenomena of diseases and the effect of drugs upon them treated as algebraical equations! It is impossible to conceive of any physician working daily by the bedside of patients, and in the dead-house, and seeing diseases as they are, framing such a system, except as a joke. It could only have been, as in fact it was, the serious work of a visionary who had thrown off the trammels of fact, and, allowing his imagination to run riot, mistook its fantastic figments for a revelation from heaven.

"That Hahnemann believed in himself and in the absolute truth of all that he taught, is beyond dispute. He was a prophet, not only to his followers, but in his own eyes. All other systems of therapeutics but his were folly, and all who pursued them were fools. That he had learning, and ability, and the power of reasoning, is abundantly clear. He saw through the prevalent therapeutical absurdities and impostures of the day: he laughed to scorn the complicated and loathsome nostrums which, even at that time, disgraced the pharmacopœias; and he exposed with no little skill and success the emptiness and worthlessness of most of the therapeutical systems which then and theretofore had prevailed in the medical schools; and then he invented and proclaimed a system of his own at least as empty and as worthless as any that had gone before. In this, I suppose, there is nothing very strange; for it is only the broadest intellects (and his was an essentially narrow one) which are capable of treating the offspring of their own brains with the severe impartiality they manifest in other cases."

The speaker then discussed the various arguments and facts alleged to support the homœopathic doctrine. He referred to the meagre and unreliable statements of the Organon and the contradictions found there; the great and inevitable sources of error in the Hahnemann system of proving and of recording cases; the astonishing theory of infinitesimal doses.

He referred then to some of the changes that had been brought about in

MODERN HOMŒOPATHY.

One of these is the hypothesis which converts homœopathy into antipathy. It is to the effect that all medicines have opposite effects, according as they are given in large or in small doses, and that when, as the consequence of proving on the healthy person, a drug is found to excite the symptoms of a disease, it cures that disease by its opposition to it when given in small doses.

The speaker showed also that homœopathy had as yet furnished no genuine and reliable statistics as to its therapeutical value.

Dr. Bristowe concluded with a discussion of the relations between homœopathy and orthodox medicine.

"So far, gentlemen, I have discoursed only on homœopathy as a science and an art. I wish to add a few words on homœopathists as men, and as members of our common profession.

"That a very strong feeling of hostility should have arisen early between orthodox practitioners and homœopathists is not to be wondered at, when we consider, on the one hand, the arrogance and intolerance which Hahnemann displayed, at any rate in his writings, and on the other hand the contempt which experienced physicians felt and freely expressed for him and his whimsical doctrines. Nor is it to be wondered at that this variance should still be maintained; for homœopathy is still a protest against the best traditions of orthodox clinical medicine; and there is a natural tendency among us still to look upon homœopathic practitioners as knaves or fools. But surely this view is a wholly untenable one. That all

HOMŒOPATHISTS ARE HONEST MEN

is more than I would venture to assert; but that in large proportion they are honest is entirely beyond dispute. It is quite impossible that a large sect should have arisen, homœopathic schools and hospitals have been established, periodicals devoted to homœopathic medicine be maintained, and a whole literature in relation to it have been created, if it were all merely to support a conscious imposture. No, gentlemen, the whole history of the movement and its present position are amply sufficient to prove that those, at any rate, who take the intellectual lead in it are men who believe in the doctrines they profess, and in their mission; and who practise their profession with as much honesty of purpose and with as much confidence in their power to benefit their patients as we do. That all homœopathic practitioners are men of ability and education it would be absurd to maintain; but it is absolutely certain that many men of ability and learning are contained within their ranks. If you care to dive into homœopathic literature, you will find in it (however much you may differ from the views therein inculcated) plenty of literary ability; and I have perused many papers by homœopaths on philosophical and other subjects unconnected with homœopathy which prove their authors to be men of thought and culture, and from which I have derived pleasure and profit. Again, I will not pretend that even a considerable proportion of homœopaths are deeply versed in the medical sciences; yet they have all been educated in orthodox schools of medicine, and have passed the examinations of recognized licensing boards; so that it must be allowed that they have acquired sufficient knowledge to qualify themselves for practice. And some among them possess high medical attainments.

"But it may be replied, if these men are honest and educated, and at the same time duly qualified practitioners in medicine, how can they believe, and how can they practise, such a palpable imposture as homœopathy? Well, gentlemen, it is very difficult to account for the beliefs and

VAGARIES OF THE HUMAN INTELLECT.

It is only occasionally that our convictions are the result of conscious reasoning. For the most part they arise in the mind, and take possession of it, we know not how or why; and our reasonings in regard to them (if we reason at all) are merely special pleadings prompted by the very convictions they seem to us to determine—in other words, they are not the foundations of our beliefs at

all, but exhalations from them. It is not surprising, therefore, that, even on matters of supreme importance, irreconcilable differences of opinion prevail, aye, amongst men of high integrity and cultivated intellect. And if we desire to live broad and unselfish lives, we must be slow to condemn all those who entertain convictions which to us seem foolish or mischievous and logically untenable, or to refuse to co-operate with them.

"There are few, even of the best among us, who have not weak points in intellect or character. And it would be deplorable, indeed, if, for example, those of us who look on spiritualism as one of the grossest follies of the times in which we live, were to scout the distinguished chemists and the great writers who devoutly belief in it; or were to refuse to do homage to the conspicuous abilities and high character of a great judge, because, throwing off the judicial impartiality which befits a judge, and acting under the influence of prejudice, emotion, and ignorance, he has made himself the leader of all the hysterical sentimentalism of the day in a crusade against experimental physiology in this land of Harvey and of Hunter! The remarks just made apply especially to beliefs in relation to those matters which are incapable of exact scientific proof, and in which the feelings are largely involved—pre-eminently, therefore, to religion, to politics, and to medicine.

"I ask you, gentlemen, to forbear with me, if I push my arguments to their logical conclusion, and venture now to express an opinion which is opposed to the opinion which many, perhaps most, of you entertain. I do not ask you to agree with it; still less do I ask you to adopt it. But I ask you to consider it; and I am content to believe that, if it be just, it will ultimately prevail. It is that, where homœopathists are honest, and well-informed, and legally qualified practitioners of medicine, they should be dealt with as if they were honest and well-informed and qualified.

"I shall not discuss the question whether we can, with propriety or with benefit to our patients, meet

HOMŒOPATHS IN CONSULTATION.

I could, however, I think, adduce strong reasons in favor of the morality of acting thus, and for the belief that good to the patient would generally ensue under such circumstances. I shall not consider at length whether the dignity of the profession would be compromised by habitual dealing with homœopathists. But I may observe that it is more conducive to the maintenance of true dignity to treat with respect and consideration, and as if they were honest, those whose opinions differ from ours, than to make broad our phylacteries and enlarge the borders of our garments, and wrap ourselves up, in regard to them, in Pharisaic pride. I appeal, gentlemen, in support of my contention to other considerations. It has been held, that to break down the barriers that at present separate us from homœopathists, would be to allow the poison of quackery to leaven the mass of orthodox medicine. But who that has any trust in his profession, any scientific instinct, any faith in the ultimate triumph of truth, can entertain any such fear? All the best physicians of old times, all the greatest names in medicine of the present day, are with us, all science is on our side; and we know that, as a body, we are honest seekers after truth. What have we to fear from homœopathy? Bigots are made martyrs by persecution; false sects acquire form and momentum and importance mainly through the opposition they provoke. When persecution ceases, would-be martyrs sink into insignificance; in the absence of the stimulus of active opposition, sects tend to undergo disintegration and to disappear. The rise and spread of homœopathy have been largely due to the strong antagonism it has evoked from the schools of orthodox medicine, and to the isolation which has thus been imposed on its disciples. If false, as we believe it to be, its doom will be sealed when active antagonism and enforced isolation no longer raise it into fictitious importance. At any rate, breadth of view and liberality of conduct are the fitting characteristics of men of science."

In the subsequent discussion Dr. Long Fox criticised Dr. Bristowe's last remarks and said: If a homœopathic practitioner, alleging that the same remedies were used, the difference being only in name, asked an honorable member of a most honorable profession to associate with him in the treatment of a case, it appeared to him to be like asking the Archbishop of Canterbury to associate with the high priest of the lowest fetish in Central Africa. Why were the adherents—he would not say the victims—of homœopathy to be found among men eminent in piety, sanctity, and benevolence? He believed it was really because they thought that God acted habitually miraculously. But as a reverend profession (as Bishop McDougall had called them), they ought to refuse to countenance so unphilosophical a view of the great First Cause. It was surely a much grander view of the Almighty to believe that he always acted by the grand laws that He had Himself laid down. He hoped that Dr. Bristowe would not suppose that he disagreed with anything he had said. He ventured only to differ in regard to the remarks in the latter portion of the Address.

Dr. Bristowe, in reply, said he knew he had expressed some views not shared by the majority of the members, and he was not surprised at the observations of his friend Dr. Fox.

## New Instruments.

### NEW INSTRUMENTS FOR THE FINDING AND EXTRACTION OF BULLETS.

By FANEUIL D. WEISSE, M.D.,

NEW YORK.

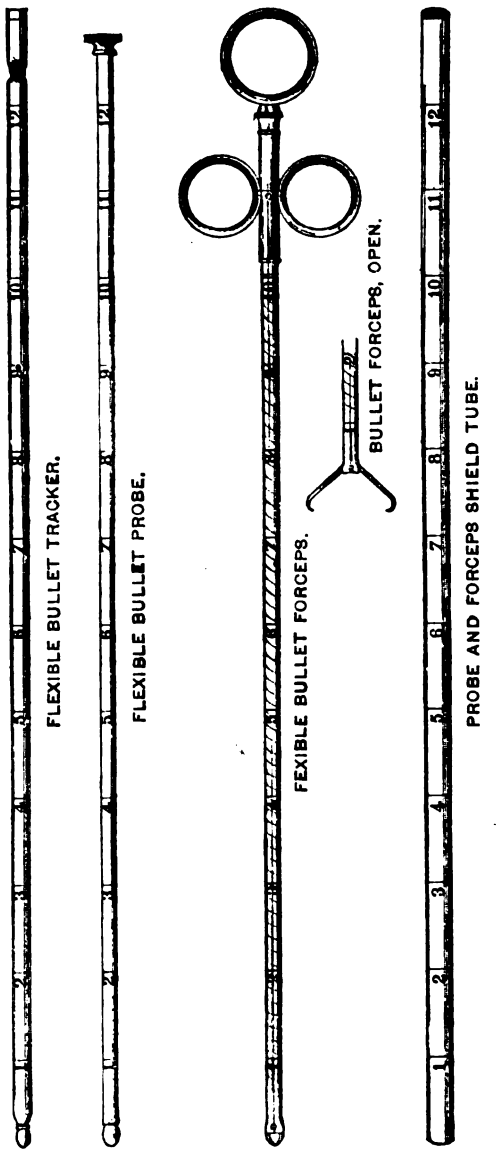
EXPERIMENTS on the cadaver, with the following instruments, would seem to warrant presenting them to the attention of the profession; they are:

A flexible bullet-tracker,
A flexible bullet-probe,
A flexible bullet-forceps,
A probe and forceps shield-tube.

*The flexible bullet-tracker*, is a rubber tube, with a porcelain (Nélaton) probe tip, fixed into and projecting at its end; the tube is loaded with metal (No. 12 bird-shot) to weight it, and its surface is marked off in inches. It is used as follows: Placing the patient in a position to make the wound-track dependent, the instrument is, after being lubricated with carbolized vaseline or oil (1 to 40), made to enter the wound, by its porcelain end; it is allowed, with a slight guidance, to advance by its own weight, and its distance of penetration may then be read off. There is a possibility, out of a number of introductions,

that the porcelain end may effect a marking from the lead, by contact with the bullet, though the pliability of the instrument militates against it.

*The flexible bullet-probe* is a rubber tube, within which is fixed a porcelain- (Nélaton) tipped copper (for flexibility) probe; the tip projecting from the end of the tube, and the surface of the tube being marked off in inches. It is used as follows: After the bullet-tracker has determined the course and depth of the bullet-wound, the probe is introduced



for the same distance, and being stiffer than the tracker, it is better adapted to obtain a tracing on the porcelain tip from the ball.

*The flexible bullet-forceps* is a modification of the instrument, known as "Tiemann's Œsophageal Forceps." It is a tube made of a spiral ribbon of steel, through which a rod plays, back and forth; at the end of the rod are two opposed tenacula (the ordinary bullet-forceps jaws), which are opened by the forward motion of the rod crowding the tenacula against a fixed bar, which covers the end of the interior of the tube between the tenacula; the forceps is closed by retracting the rod, which draws the tenacula into the tube. The surface of the tube is marked off in inches.

*The probe and forceps shield-tube* is a rubber tube of only sufficient calibre to introduce the probe and forceps; the surface of the tube is marked off in inches. Given a bullet-wound, at the end of which a bullet has been determined by a lead-marking on the porcelain end of the tracker or probe, the shield-tube is used in the following way: The probe, lubricated as above, is entered into the shield-tube so as to allow the porcelain tip to project; the shield-tube is in turn lubricated, and the two are passed into the wound for the distance determined by previous examinations as to the locality of the bullet; a lead-marking is effected by manipulation of the probe and shield-tube as one instrument; the probe is now withdrawn and the shield-tube left in the wound; the lead-tracing is again verified on the porcelain tip of the probe, which establishes the bullet as opposite the end of the shield-tube. The forceps is now entered within the shield-tube, and passed along so as to project at its end, where it will recognize, by sounding, the metal impact of the bullet; open the forceps-jaws, and grasp the bullet; then withdraw, by careful manipulation, the bullet, the forceps, and the shield-tube all together.

The tracker is made in two sizes—12 and 18 mm. in circumference respectively. The probe is 12 mm. in calibre. The forceps has a circumference of 12 mm. The shield-tube has a calibre of 14 mm. All the instruments may be made of any length required; those experimented with averaged 30 ctm.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August* 10, 1881, *to August* 27, 1881.

McKee, J. C., Major and Surgeon. By direction of the Secretary of War, the leave of absence on surgeon's certificate of disability, granted in S. O. No. 177, August 19, 1880, is extended three months. Par. 3, S. O. 189, A. G. O., August 18, 1881.

Hubbard, V. B., Asst. Surgeon. Promoted to the rank of Major and Surgeon in the Medical Department, to take effect from the 10th of August, 1881; vice White, deceased.

Bushnell, George E., Asst. Surgeon. Granted leave of absence for fourteen days. S. O. 145, Headquarters Department Dakota, August 9, 1881. Relieved from duty at Fort Yates, D. T., and to report to commanding officer Fort A. Lincoln, D. T., for temporary duty, on expiration of leave of absence. S. O. 146, Headquarters Department of Dakota, August 11, 1881.

Webster, Warren, Major and Surgeon. Granted leave of absence for twenty days. S. O. 149, Department of the East, August 24, 1881.

McClellan, Ely, Major and Surgeon. Relieved from duty in the Department of the Columbia, and to proceed to Louisville, Ky., and report by letter, upon his arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

Woodhull, A. A., Major and Surgeon. Relieved from duty in the Department of California, and to

proceed to New York City and report by letter, upon his arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

BROWN, HARVEY E., Major and Surgeon. Relieved from duty in the Department of Texas, and to proceed to New York City and report by letter, upon his arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 22, 1881.

HUBBARD, VAN BUREN, Major and Surgeon. The leave of absence granted him in S. O. 169, A. G. O., August 26, 1881, is extended eight months, with permission to go beyond sea. S. O. 193, A. G. O., August 23, 1881.

DICKSON, J. M., Captain and Asst. Surgeon. Relieved from duty in the Department of the Columbia, and to proceed to New York City and report by letter, upon arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

COWDREY, S. G., Captain and Asst. Surgeon. Relieved from duty in the Department of the Platte, and to proceed to New York City and report by letter, upon arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

SHANNON, W. C., Captain and Assistant-Surgeon. Relieved from duty at Fort D. A. Russell, Wyo., and assigned to duty as Post Surgeon at Fort Thornburgh (junction of White and Green rivers), Utah. S. O. 81, Department of the Platte, August 22, 1881.

GARDNER, E. F., Asst. Surgeon. Upon being relieved by Asst. Surgeon Bushnell, is relieved from duty in Department of Dakota, and will comply with Par. 3, S. O. 171, A. G. O. S. O. 150, Department of Dakota, August 17, 1881.

ROBINSON, SAMUEL Q., First Lieutenant and Asst. Surgeon. Relieved from duty in the Department of Dakota, and to proceed to Boston, Mass., and report by letter, upon arrival there, to the Surgeon-General. S. O. 193, A. G. O., August 23, 1881.

POWELL, J. L., First Lieutenant and Asst. Surgeon. Granted leave of absence for one month, to take effect as soon as the Medical Director of the Department shall have completed certain inspection duty at Fort Stockton, Texas. S. O. 99, Department of Texas, August 13, 1881.

BUSHNELL, G. E, Asst. Surgeon. Relieved from temporary duty at Fort A. Lincoln, D. T., to take effect on his arrival at that post, and to proceed to Fort Ellis, M. T., and report to the commanding officer for duty at that post, to relieve Asst. Surgeon E. F. Gardner. S. O. 150, Department of Dakota, August 17, 1881.

TREPHINING IN EPILEPSY.—Mr. J. F. West, of Queen's Hospital, Birmingham, some time ago reported a case of traumatic epilepsy successfully treated by trephining. He now offsets this by reporting a case of epilepsy where trephining failed entirely to help. The patient was a girl of twenty-two years, who had had what was probably idiopathic epilepsy since her fifth year. As she had sustained a severe injury just above the brow, which had left a cicatrix and thickened periosteum, it was thought that possibly this injury helped to keep up the condition. So, as medicines failed to relieve the patient at all, Mr. West trephined. He operated antiseptically, and the case illustrated the value of Listerism in such operations. The fits continued, however, and the girl finally became demented.

# Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending August 27, 1881.

| Week Ending | Typhus Fever. | Typhoid Fever. | Scarlet Fever. | Cerebro spinal Meningitis. | Measles. | Diphtheria. | Small-pox. | Yellow Fever. |

* 38 Cases in Public Institutions.

WHAT IS PYÆMIA?—According to *Delafield*, under the name of pyæmia are commonly understood several different conditions, giving rise to different lesions:

1. Septicæmia.—In this, some portion of the body is in a condition of gangrene; that is, the tissues are not only dead but decomposing, with the evolution of gases, the softening and liquefaction of the solid parts, and the development of minute organisms, either animal or vegetable. The gangrenous fluids thus produced are, apparently, absorbed by the lymphatics and blood-vessels, and are thus able to produce marked symptoms during life, and to produce death.

2. Simple pyæmia.—Persons who have suppurating wounds or abscesses may, without much change in the wound or abscess, be seized with rigors followed by fever, become jaundiced, and die.

3. Metastatic pyæmia.—This is a very different condition from the other two, and may be accompanied with marked lesions. By the agency of various changes about the wound, substances are absorbed which produce in various parts of the system multiple abscesses and hemorrhagic infarctions.

*Agnew.*—The fevers that follow wounds are divided into three kinds:

1. Simple traumatic infective fever.
2. Secondary traumatic fever.
3. Complicated traumatic infective fever.

The secondary traumatic fever may imitate a hectic fever.

The complicated traumatic infective fever includes what are generally known as septicæmia and pyæmia. But Agnew discards the term pyæmia.

*Billroth* classifies the fevers following wounds into—

1. Primary traumatic fever.
2. Secondary traumatic fever.
3. Septicæmia.
4. Pyæmia.

By septicæmia he understands a constitutional acute disease which is due to the absorption of various putrid substances into the blood, which is thereby spoiled so that it cannot fulfil its physiological function.

Pyæmia is a disease which we suppose to be due to the absorption of pus or its constituents into the blood. It is symptomologically characterized by intermittent attacks of fever, etc., and in its pathological anatomy by abscesses and diffuse inflammations. It is clinically distinct from the other varieties.

*Fordyce Barker* believes septicæmia and pyæmia to be distinct clinically, and, probably, distinct pathologically. There are more evidences of cerebral disturbance, more diarrhœa, fever, chills, and the symptoms come on earlier in septicæmia than in pyæmia.

*Greenfield* considers pyæmia and septicæmia to be distinct, but attributes both to an invasion of the system by microscopic organisms.

*Erichsen.*—Pyæmia is a name applied to a group of pathological conditions. These include (Virchow) (1) leucocytosis, (2) the formation of thrombi with resulting emboli and abscesses, and (3) an absorption of ichorous matter producing the condition known as septicæmia.

*Gant* and *Ashhurst* adopt assentially the same view as Erichsen.

*Aitken.*—Pyæmia is a febrile affection generally sequent on wounds, suppurative inflammation of bone, the puerperal state, or surgical operations, resulting in the formation of secondary abscesses in the internal visceral organs (most frequently in the lungs, the liver, kidneys, spleen, and brain), and also in the joints and connective tissue—sometimes, but not necessarily, associated with phlebitis or embolism. Under this head there is a class of cases which are prolonged and essentially chronic, in which fever does not reach a high degree of temperature, but in which the suppurative tendency is necessarily expressed in many organs and in different parts of the same organ. This is in reality *septicæmia.* There is another class of cases in which superadded to the septicæmia is the suppurative tendency which expresses itself in multiple abscesses, this is *true pyæmia.*

*Virchow* denies that there can be proved to exist any such thing as morphological pyæmia. The name, as designating a definite change in the blood, must be abandoned. As commonly used it covers one or more of the three pathological conditions referred to in the quotation from Erichsen.

*Callender* ("Holmes' Surgery"), adopts essentially Virchow's view, and urges that the name pyæmia be applied only to the condition in which there is formation of thrombi, with fibrinous infection and metastatic abscesses therefrom.

*Bristowe* ("Reynolds' System").—Pyæmia is a disease the most characteristic features of which are (1) its supervention on certain special conditions of the system; (2) the occurrence of rigors, with perspirations; (3) the presence of jaundice; (4) the formation of external abscesses; (5) the great prostration and early death; (6) the occurrence of certain characteristic lesions easily recognized after death.

*F. H. Hamilton.*—The specific causes and the precise pathological character of pyæmia are not yet fully determined. There is much probability, however, that it is a variety of septicæmia, and that it is induced by the reception into the system from suppurating depots of certain septic elements, or of elements which have undergone a gangrenous or, possibly, only a suppurative degeneration.

The symptoms are irregular chills, with profuse perspiration, great prostration, vomiting, delirium, sweet breath.

*Lidell* considers pyæmia as a species of septicæmia, or blood-poisoning; clinically distinct, however, from septicæmia, but to be arranged under the same genus.

*Wagner.*—Pyæmia is divided into two forms:

1. Septicæmia.
2. Embolic or septico-pyæmia.

Pyæmia is defined as a disease, usually acute, which starts in a purulent or ichorrous focus, and is caused by the absorption from this focus, or its vicinity, of mechanical or chemical noxious, so-called septic or putrid substances.

*Bryant.*—According to this author, traumatic fever, septicæmia, and pyæmia, are all names for one condition, viz., blood-poisoning. These different forms of blood-poisoning differ in degree, not in kind. Traumatic fever may pass into septicæmia, and septicæmia into pyæmia.

The variety of statement and of definition in the above, indicates less real discrepancy than would appear. Some of the authorities quoted are antiquated, while the more modern ones are substantially agreed in fact, if not in letter. The view that what used to be known, and still is recognized by some, as pyæmia is only a form of septicæmia, is the one generally held by modern pathologists. Pyæmia is an intenser form of septicæmia, having clinical and morphological characters of its own. The word pyæmia, however, ought to be abandoned, for its etymology conveys a wrong idea of the real pathology of the disease.

Most surgical writers have little claim to speak authoritatively on pathological points. It is noteworthy that Hamilton and Agnew, in their "Surgeries," come nearer to accuracy than the others that we have quoted.

TWO MORE MEDICAL COLLEGES.—There is soon to be established a Medical College in Texas, in connection with a new State University. Its location is not decided upon, but it will probably be in Galveston.

We have received, also, the announcement of a Medical College that is to open this fall at Denver, Colorado.

It is a generally accepted fact, that the number of medical colleges already in existence in the United States is more than enough to supply the wants of the country. This, at least, is conceded by all practitioners not directly interested in second-rate schools. It might even be added that we have quite enough first-class colleges for the country's physical good. Still, we should hardly be inclined to protest against establishing such new institutions as promised and carried out all the requirements of a higher medical education.

We very much regret that we can find nothing in the announcement of this proposed college at Denver to justify any good wishes for its prosperity.

The prospectus starts out with a discourse upon the evils of a low grade of requirements for medical degrees, and the great detriment which such a low grade causes to the public and profession. This seems promising, but a further examination reveals it to be only a very cheap kind of cant. The college, according to its announcement, will not in reality enforce a single one of these higher educational requirements. It establishes a graded course, but this, we are informed, is not obligatory. It expects a matriculation examination, but only on the most elementary subjects. It has a three years' course, but requires attendance only on two full courses, which might both be attended within eighteen months for all that the regulations say to the contrary. The college is, in fact, judging by its announcement, to be one of the same easy going diploma manufactories with which our country is already flooded.

The excuse given for its existence is the fact that

Denver is the centre of the far West, that it has forty thousand or more inhabitants, a salubrious climate and surroundings of the greatest scenic grandeur.

Of course this all sounds very well, but then everybody knows how little it means. Perhaps we should not find fault that a desire for professorial prominence animates the Western as well as the Eastern mind. But we wish that with this ambition there were exhibited a little more frankness and a little more evidence of a wish to educate the medical student as well as to elevate a few medical practitioners.

Suggestions Regarding Hypodermic Injections.—Dr. C. Mason, of Peekskill, N. Y., suggests to those who use the hypodermic syringe, that when the packing on the piston becomes worn and loose, and will not readily work, to remove the small nut at the end of the piston, take half of the packing off (it is usually in two parts), and place between them a piece of chamois-skin. Cut it round, leaving it somewhat larger than the packing. He says: "It will absorb water, swell, and completely fill the barrel of the syringe. A trial of this will convince the most sceptical of its value over all other devices to do away with the most annoying features connected with the use of the hypodermic syringe, for who has been so fortunate as to have their syringe always in working order?

"Now, as to the solution (Magendie's)—Who can say that they can prevent a sediment from forming when it has been made for a number of days? Many drugs have been named, but they are either objected to for their nature, or else they fail to preserve the solution. I can see no objection to using a fresh solution instead of a stale one. To accomplish this, make it at the bedside as follows: After determining the quantity of morphia for the case at hand, plunge the syringe (minus the needle) into water, and draw up as many minims of water as it has been determined to give minims of Magendie. Place this amount in a teaspoon, and add sulphate of morphia until it will take up no more. After the solution is completed put, say, five additional minims of water to it, stir, and be positive that all the sulphate is dissolved. The only disadvantage which may be expected is the possibility of an excess of acid in the preparation of the sulphate. But even this is extremely doubtful, and, if it were the case, the result would be of no moment, owing to the smallness of the dose. After practising this for a while, one becomes so accustomed to it that it can be done very quickly, and the difference in time is fully compensated for by the result. The air which is apt to collect in the syringe is readily expelled by holding the syringe perpendicular, with the needle upward. The liquid will gravitate to the bottom, and the air will be expelled by simply pushing upward the piston until the fluid is seen to pass from the point of the needle. The number of abscesses which follow the hypodermic use of morphine will, I think, diminish if this method is used."

Precocious Menstruation.—B. F. Zeller, M.D., Beamsville, Ohio, reports the following facts of a case of precocious menstruation:

"The child is now five months old, and began menstruating at the age of two months. It has now menstruated three times at regular intervals of four weeks, the menses lasting from three to four days. The parents came to me for advice, but as the child is very healthy there is nothing to be done. Bedford, in his work on obstetrics, relates a case where the child was as young as twelve months—reported by Dr. Rowlett, of Kentucky—but does not seem to place much faith in it."

A New Method of Combating Insomnia.—Professor Hoppe, in the *Journal d'Hygiene* (April 7, 1881), mentions a plan of treatment of insomnia which he has frequently found successful. It consists simply in rapidly closing the eyelids, twenty or thirty times in succession, and thereby causing fatigue of the depressor palpebræ muscles; this will be followed in a few seconds by an irresistible desire for sleep. The professor recommends this treatment more especially in that form of insomnia which accompanies nervous disease.—*Cincinnati Lancet and Clinic*, July 30, 1881.

This suggestion must be the remembrance of a grandmother's advice. Certainly in Virginia, we have heard of it "from the time before the war." "Several" of our patients have faithfully followed the directions—in substance like the above. Some have and some have not got the "rest" desired. But in view of "the method," we will recommend it again.—*Virginia Med. Monthly.*

What is Adulteration of Food.—A recent decision in a case of alleged adulteration of buttermilk is of interest in connection with our present new adulteration laws. The judge in this case quashed the indictment (which was for watering the milk), and defined adulteration as the addition of some unwholesome ingredient for the purpose of cheating, by making the purchaser pay more than it was worth.

Science and the Hatters.—In accordance with the principles of evolution and the development of society, human heads should be getting bigger. But according to the hatters the contrary is the case. In a letter to the *Lancet*, Mr. W. H. Smith says:

"Hatters have discovered that the human head is decreasing in size. From practical experience they can testify that hats are made of a much smaller size at the present day than they were twenty-five or fifty years ago.

"In a body of men like our soldiers and police the sizes run very small in many instances, although in these cases the men are often tall and well proportioned. The sizes of the heads of professors, doctors, etc., are always larger than those of the general public. Burns had a head of 7¼ inches in size. Formerly the size of the hats sold was frequently from 7¼ to 7⅜ inches, whereas now the average demand is for hats from 6¾ to 6⅞ inches. What is the cause of this? Perhaps some members of the medical profession may be able to throw some light upon this important question."

A New Binaural Stethoscope has been presented to the Academy of Medicine by Dr. Constantine Paul. The chest-piece is surrounded by a circular box which is connected by a tube with an india-rubber ball. Upon aspirating with the ball the box, when placed upon the skin, adheres like a cupping glass, and the rarefaction of the air in the circular sucker is said to increase the intensity of the sounds. The instrument is completed by a Y-shaped metallic branch which emerges from the apex of the chest-piece, and which terminates in two flexible tubes for insertion in the ears. Another novel arrangement which can be made in the apparatus is the addition to each terminal tube of a secondary dichotomous metallic branch, to which are again attached a couple

of terminal tubes. The further development of this system of dichotomous branching enables any number of auscultators to listen simultaneously to the same sound.

ANTISEPTIC SURGERY is gradually gaining favor amongst French operators; but an occasional manifestation against it is made by some of the older members of the profession. At the Société de Chirurgie, M. Boinet has recently returned to the same objections that were advanced some two years since by M. Lucas-Championnière. In the first place, he claims that the credit of the application of carbolic acid in surgery is not due to Lister, but to the French school, and having demonstrated this, presumably to his own satisfaction, he goes on to affirm that antiseptic surgery is both useless and dangerous. This is attempted to be proved by two facts. On one occasion M. Boinet used antiseptic dressings in a case of ovariotomy, and the patient died, "probably on account of the irritation of the peritoneum by the carbolic acid."—*Correspondence London Lancet.*

OBLIGATORY VACCINATION IN FRANCE.—After long discussion, the French Academy has adopted the following conclusions:

1. The Academy deems it urgent, and of great public interest, to enact a law rendering vaccination obligatory.

2. As to revaccination, it should be encouraged in every manner, and even imposed by administrative regulations where it is possible, especially by municipal authorities, wherever the physicians appointed by the state during the prevalence of epidemics, or the boards of health, have called attention to the necessities of this obligation.

Moreover, the Academy expresses the hope that isolation of patients affected with variola, especially in hospitals, be ordered by special legislation.

WHAT COFFEE WILL DO.—According to Dr. Bock, of Leipsic, coffee and tea are the chief causes of the nervousness and peevishness of our time.

Dr. Henry Segur takes the opposite ground, and enumerates the blessings which the infusion can produce.

It is a mental and bodily stimulant, assisting to convert the blood into nervous tissue, and thus recruit the nervous moving and thinking faculties.

It lessens the waste of tissue, and thus lessens the amount of food necessary to support the system.

It will often cut short and cure attacks of intermittent fever.

In typhus fever it increases the excretion of urea, and so far purifies the blood without increasing tissue metamorphosis.

It tends to lessen coma and low delirium. It is Dr. Segur's chief reliance in yellow fever.

It is useful in spasmodic asthma, whooping-cough, and hysterics. It is a diuretic in cardiac dropsy. In opium-poisoning its efficacy is well known.

After a heavy meal it relieves the sense of oppression and helps digestion.

It is a disinfectant and deodorizer.

Habitual coffee-drinkers generally enjoy good health, and live to a good old age.

THE VALUE OF DIGITALIS.—A discussion upon this subject was opened by Dr. H. C. Wood, at a meeting of the Philadelphia County Medical Society, March 23d.

Dr. Wood asserted that digitalis has a peculiar effect upon the heart-muscle, steadying it, and improving its nutrition. Its use in heart disease is well known. It must sometimes be given in large doses, as much as half a drachm, but small doses should always be tried first. The drug should not be used in aneurism as is sometimes done. It is useful in acute diseases with failing heart, as in the latter stages of pneumonia. In one case of alcoholic pneumonia, the patient's life was saved by giving the drug in ten-drop doses every two hours until the pulse came down from 160 to 60.

As regards the cumulative action, the remedy acts slowly in producing its full effects, and these effects are very permanent. Digitalis acts cumulatively, more especially when it does not affect the kidneys. The practical point is, therefore, to watch the kidneys, and if the urine is not being increased, we may expect a cumulative effect upon the heart.

Digitalis is very useful in syncope and collapse. Inject twenty minims of the tincture, and expect to find the effect in half an hour.

While digitalis cannot be used entirely without danger, it is harmless if carefully administered.

As regards the kind of preparation, he thought the infusion more effective and more generally used, simply because it was generally given in larger doses.

Digitalin was not an active principle, but merely the purified extract, and it was, he thought, unreliable.

ELECTRICITY FOR DYSMENORRHŒA AND THE UNDEVELOPED UTERUS.—Dr. J. Dixon Mann reports (*Lancet*) cases of dysmenorrhœa of "neuralgic" or spasmodic origin, cured by use of the constant current of about twenty cells. This was used for ten minutes three times a week.

By persistent use of the same agent, an undeveloped uterus, 1¾ inch long, grew to the length of 2¾ inches. The patient, a girl of twenty years, then began to menstruate for the first time.

THE MEDICAL CLASS AT THE UNIVERSITY OF BERLIN numbers 576 students. The whole number of students in the University is 3,709.

THE USE OF BOVINE VIRUS for vaccination does not yet seem to make much headway in England. According to the correspondents of the London Medical Journals, the lymph so far supplied has not proved very active. Furthermore, the National Vaccine Establishment has not yet made arrangements to supply the profession with calf-lymph.

All this will seem rather surprising to New York and New England readers, who have long been supplied with reliable calf-lymph, and plenty of it.

MEDICAL SOCIETY OF THE COUNTY OF WESTCHESTER, N. Y.—The annual meeting of this society was held at White Plains, Tuesday, June 21, 1881, when the following officers were elected: President, C. H. Judson, M.D.; Vice-President, R. B. Coutant, M.D.; Secretary, J. Francis Chapman, M.D., Katonah; Treasurer, A. M. Campbell, M.D.; Censors, Drs. Pelton, Linson and Helm; Essayists, Drs. Chapman, Pelton, and Parsons.

WHAT BEER DOES—IN INDIA.—The British army reports from India show that the deaths of those who use ale are twelve in one thousand, just double the natural rate; among those who use porter the death-rate is twice as great as with ale. Dr. Edmunds says in England two barkeepers die to one laborer. The life-insurance tables in that country, carefully kept, show a vast disproportion in the death-rates of moderate drinkers and total abstainers.

## METASTATIC PAROTITIS.

By R. C. M. PAGE, M.D.,
NEW YORK.

Case I.—Mrs. E. W——, aged thirty-eight, was admitted to the Woman's Hospital, April 20, 1870, with rectocele and lacerated perineum. Being in fair condition, she was operated upon April 26th. Silver sutures were used to bring the denuded surfaces together.

April 27th.—Patient came out from the ether badly, and is still restless and uneasy. I gave her, at 10 P.M., sol. morph. Magendie, gtt. x. hypodermically.

April 28th.—Patient rested badly and has no appetite. Vomited at noon. At 2 P.M. she was seen by Drs. T. A. Emmet and J. G. Perry, and all agree that the vomiting was probably due to the morphine. Pulse, however, 110 and excited; temperature, 100° F.; respiration, normal. Ordered bits of ice and cold tea, in small quantities for thirst, and beef-tea as nourishment. Complains of no pains.

April 29th.—Patient was very uneasy last night. Vomits at intervals to-day. Brandy and beef-tea given per rectum. This afternoon there is pain in right jaw, and upon examination *the right parotid gland is found to be slightly swollen.* Pulse, 115; temperature, 101° F. Patient was now questioned in regard to mumps, and she stated that, as well as she could remember, she once had mumps on the left side, but did not think that she ever had it on the right. The case was therefore thought to be probably one of mumps occurring just at the time of the operation, although the coincidence was regarded as a very curious one.

May 1st.—Patient has steadily grown worse. Seen to-day by Drs. T. A. Emmet and John H. Ripley, and the parotitis is regarded as metastatic. The sutures were carefully removed and the parts thoroughly cleaned with carbolic lotion. Enemata of quinine, brandy, and beef-tea given.

May 2d.—Prof. W. H. Van Buren was called in consultation, and saw her at 2 P.M. He considers it "an isolated case of rapid blood-poisoning." Same treatment to be continued. Parotid gland now much swollen, so that patient cannot open her mouth sufficiently to protrude her tongue. Sordes about the teeth. Pulse, 160; temperature, 102° F.; respiration, 12. Muttering delirium. She gradually sank, and died on Tuesday, May 3d, at 12.50 P.M.

Autopsy by Dr. Francis Delafield showed all organs healthy except the following, viz.:

*First.*—Left lung compressed; bronchi thickened and contained muco-pus.

*Second.*—Intestinal mucous membrane much congested, probably from medication.

*Third.*—Right parotid gland the seat of suppurative inflammation, with about half-teaspoonful of pus present.

Case II.—Miss U. R. C——, thirty-four years of age, was admitted to the Woman's Hospital, October 6, 1870, with retroversion of the uterus, with endometritis and dysmenorrhœa. Treated with intra-uterine applications of carbolic acid and glycerine (℥j.—ʒj.), and warm vaginal injections.

November 16th.—Patient is just over menstruation, which has been attended with less pain than for years.

November 23d.—Seen by Dr. J. C. Nott, who placed the uterus in position and introduced a retroversion pessary.

November 26th.—It being an unusually fine day, and the patient much improved, I unfortunately yielded to her request to attend a matinée at the Academy of Music. Upon her return she felt quite well, but at 8 P.M., complained that the pessary caused her pain. It was therefore removed.

November 27th.—Patient did not rest well last night, and has chilly sensations to-day. Pulse 90, but excited. 8 P.M.—Complains of aching pains in hypogastric region.

November 28th.—Patient rested badly last night, and to-day has irritable stomach. Vomited at 8 P.M., and seen by Dr. Nott, who orders hot poultices over abdomen and sol. morph. Magendie, gtt. x. hypodermically. Beef-tea as nourishment.

November 29th.—Patient rested quite well last night, and feels better to-day. Pain and tenderness in hypogastric region much less.

November 30th.—Patient appears comfortable. Rested well last night. Pulse, 86; temperature, 100° F. Seen by Dr. T. A. Emmet. There is no pain or tenderness under pressure over the whole surface of the abdomen, and she is thought to have escaped what threatened to be an attack of peritonitis.

December 1st, 7 P.M.—Patient appeared to be doing well, but complained of pain in left cheek. Upon examination, *the left parotid gland was found to be slightly enlarged, red, and painful.* Stated that she had always thought she had mumps once, but concluded that she must have been mistaken. Ice applied gave much relief. Although the patient appeared to be really convalescent, I nevertheless felt misgivings at the appearance of the "mumps," and I determined to call in some of the consulting staff next morning.

December 2d, 1 P.M.—Pulse, 86; temperature, 102° F.; respiration normal. Left cheek much swollen and painful. *Right parotid also slightly enlarged.* Prof. T. M. Markoe now saw her, and relieved me very much by concluding that it was a severe attack of mumps.

December 4th.—Patient rested well last night with sol. morph. Magendie gtt. x. Pulse this morning, 82; respiration, 19. Skin pleasant. Temperature, 99¼° F. She feels much better and swelling subsiding. Dr. Markoe saw her again; also Drs. A. C. Graham and J. C. Nott. Diagnosis of mumps confirmed. Although it appeared that I had made an unnecessary stir by calling a consultation in a case of mumps, I, however, consoled myself with the idea that, if it should prove to be another case of metastatic parotitis, I had certainly lost no time in calling attention to it.

December 5th.—Did not rest well last night. Pulse, etc., the same. No pain except in cheeks, and, owing to difficulty in swallowing since Saturday, she has had enemata of beef-tea and brandy. 7.30 P.M.—Sol. morph. Magendie, gtt. x., given hypodermically. At 10 P.M. I was hurriedly informed by Assistant House Surgeon A. C. Graham that the patient was not breathing. The œdema was extensive in the neck and about the region of the glottis, and she had gradually become asphyxiated. No pulse at the wrist, but the heart still beating rapidly, though feebly. Drs. T. A. Emmet and George A. Peters were sent for, but before they arrived the patient had been restored to consciousness by shifting her position, artificial respiration, etc. It was therefore decided not to perform tracheotomy at present.

December 6th, 9.30 A.M.—Patient rapidly growing worse. Pulse 150. Both parotids enormously swollen. There is also a swelling in left arm, subsultus tendinum, muttering delirium, etc. She died suddenly at 12.30 P.M.

December 7th.—Autopsy by Dr. Francis Delafield revealed acute diffuse peritonitis, with copious purulent exudation. Both parotid glands the seat of suppurative inflammation, with the presence of a very small quantity of pus. Metastatic abscesses in other organs, and one in left arm. Atheroma of aortic valves.

CASE III.—Reported by Dr. W. H. Johnston (formerly of this city, now of Selma, Ala.), in the *American Journal of Obstetrics*, vol. iii., p. 318, 1871. A boy, aged seven, who had always been healthy, went to school on Monday morning, April 11, 1871, apparently well. The mother states that in the afternoon of same day he complained of being chilly. Restless during the night, and had some fever.

April 12th.—The mother states that patient has no appetite, and she noticed to-day a swelling below the left jaw, attended with pain.

April 13th.—Mother states that little or no change occurred until this afternoon, when he vomited a greenish fluid. She then sent for Dr. Johnston, who now saw the patient for the first time. Found his face flushed, tongue slightly coated, left tonsil red and swollen, and some pharyngitis present. Patient could not open his mouth wide by reason of the swelling below the left jaw, which was concluded to be due to *inflammation of the parotid gland*. Temperature increased, but not to a remarkable extent. Pulse 112, full, and hard. Respiration normal. Complained of pain nowhere except when the swollen gland was touched. Had never had mumps. Pressure with both hands over entire surface of abdomen unattended with pain or tenderness, and there was no tympanites. Heart and lungs normal.

April 14th.—Vomited a greenish fluid this morning. Rapidly sank, and died at 2 P.M.

Autopsy by Dr. W. H. Johnston, twenty-one hours after death, in presence of Drs. John H. Ripley and Frank Deems (the latter now of Augusta, Ga.). He was astonished to find acute diffuse peritonitis, with copious exudation of pus. Intestines much congested, but not perforated, as was proved by inflating them with a Davidson's syringe, the nozzle of which was introduced into the rectum. Liver normal. The swelling in the neck was cut into, and found to be the *left parotid gland;* no pus in it. No abscesses discovered in any of the other organs.

The boy was sick only *three days*, complained of *no pain* about the abdomen, except when the bowels, which were regular, moved on Wednesday; and he was up and walking about six hours before death.

CASE IV.—History at present incomplete. On Tuesday, October 29, 1878, while in Vienna, I visited the General Hospital, and went through the puerperal fever ward, with Professor Gustav Braun. Among the patients in this ward I noticed a woman about twenty-five years of age, who had *swelling of the right parotid gland*. Professor Braun informed me that it was of rare occurrence; but, as affecting the prognosis, "It is very bad," said he, with a shrug of the shoulders, "and they all die, I believe." She died in a few days. No post-mortem notes in my possession at present.

CASE V.—History furnished by Dr. John H. Ripley, New York. Mrs. B——, aged thirty-five years, during the seventh month of pregnancy, was seized with convulsions on the morning of September 23, 1879. She had four convulsions in all during that day. Urine was found to contain hyaline and granular casts, and to be highly albuminous. From this time until the 25th September she had irritable stomach, rapid pulse, and temperature slightly above normal, but no more convulsions. She was delivered of a dead fœtus in the afternoon of the 25th, without any further unfavorable complication. The case now appeared to progress favorably, except that the pulse was rather rapid, and temperature varying from 101° to 102° F. No perceptible change occurred until the morning of the 29th, when the *left parotid gland became swollen and tender*. I at once concluded that it was a metastatic inflammation, my attention having been first called to the serious nature of this complication in practice by Dr. R. C. M. Page, in 1870. The lochial discharge was normal, and there were no evidences of pelvic trouble. During the evening of the same day the *right parotid gland also commenced to swell*. Meanwhile the other had enlarged so as to very much disfigure her appearance. Dr. W. R. Gilette now saw her, and the diagnosis of metastatic parotitis was confirmed. From this time on the symptoms rapidly became more alarming. Pulse, 156; temperature, 102° F.; respiration varying. Her mind became clouded, and this was followed by muttering delirium. Although the swelling of both parotid glands had now become rather diminished than increased in size under the influence of hot poultices, she sank rapidly, and died on the evening of September 30th. Subsequent to the miscarriage the urine was normal in quantity, and contained less albumen. No autopsy.

CASE VI.—John Goldbach, aged twenty-one years, laborer, was admitted to the St. Francis Hospital, New York, in the service of Dr. George F. Shrady, June 6, 1881. Had always been healthy until May 27th, when accident occurred. While engaged in putting a belt on a wheel with a stick, the latter was caught, and struck him on the abdomen, about three inches to the right of and below the navel. He was knocked down, and immediately began to suffer great pain, which, however subsided in a short time, and no severe symptoms occurred until two days afterward, when a localized peritonitis began. When admitted he was suffering from general peritonitis. Patient was kept under the influence of morphine, hypodermically administered. Respiration, 14. Condition remained unchanged until June 20th, when the *left parotid gland commenced to swell*. Hot poultices were applied, and in a few days the swelling commenced to subside.

June 24th.—Patient appears to be improving, but has some diarrhœa.

June 26th.—Patient growing worse; pulse rapid and feeble; temperature, 102° F. Over the site of the contusion the abdominal walls had become thinner, by pressure from an abscess, which, July 4th, perforated the intestine. He died July 6th. No post-mortem notes furnished.

Inflammations of the parotid gland may be divided into four classes: 1, traumatic; 2, idiopathic; 3, symptomatic, and, 4, metastatic. Of the first two I shall not speak; of the last two I would designate as *symptomatic* those cases of parotitis which are mentioned by various authors as appearing in the course of *infectious* diseases, in which the cause is often probably due to the infection itself; and as *metastatic*, those in which the parotitis is a secondary complication, following injuries, surgical operations, and acute inflammations, with purulent exudation, as described in the foregoing cases. In these the

cause is probably due to *embolism*. Such theories as the absorption of pus into the blood-vessels, the purulent diathesis, the retrograde metamorphosis of fibrin into pus, the influence of nervous action, and absorption by the lymphatics, have all been discarded by scientific men as causes of these secondary complications. Veins, however, surrounded by tissues that are undergoing inflammatory processes, have formed in them, under certain predisposing conditions, coagula that are presumed to be septic in their character. These clots in turn become disintegrated, and the débris thus formed is carried along in the general circulation until it lodges somewhere. As a result, local irritation, followed by inflammation, occurs. If the patient lives long enough, the inflammation generally becomes suppurative. Occasionally there is such obstruction in the minute blood-vessels that gangrene of the part obtains. How these disintegrated clots sometimes get through the liver or lungs, or both, without injury to those organs, and finally lodge and produce metastatic inflammation somewhere else, is not clearly explained. In such cases it may be that the septic material does not possess sufficient malignity to affect the liver or lungs, while it would cause inflammation in other more sensitive parts. But, however this may be, or whatever be the true theory of blood-poisoning adopted, the practical fact remains, that metastatic inflammation may, and does, occur while the liver and lungs are normal. The embolic theory probably explains why autopsy revealed but a very small quantity of pus in two of the foregoing cases, and its absence altogether in one. In the latter case the patient died before suppuration commenced, and in the other two the suppurative process appears to have just commenced. Had pus been absorbed into the blood-vessels and deposited in these glands, it would probably have been found in all. In regard to *which* of the parotid glands is most frequently the seat of metastatic inflammation, statistics appear to be wanting. If we include the case of President Garfield, in which the right parotid gland is affected, we have out of seven cases the right parotid gland affected in three, the left in two, and both in two. The number of these cases is not sufficient to warrant any conclusion on this point, but theoretically I should regard the right parotid gland as liable to be more frequently affected, as the septic material would pass in a more direct course from the heart to it than to the left.

As affecting the prognosis of a case, authors agree that the appearance of parotitis, in the course of infectious diseases, forms a grave and very unpleasant symptom. As a metastatic affection, especially when secondary to peritonitis, I regard it as certainly a very serious, if not a fatal complication.

31 West Thirty-third Street, New York,
August 30, 1881.

A New Gaseous Disinfectant.—M. Peyrusson has communicated to the Académie des Sciences the result of a series of experiments made with the fumes of nitrous ether. From these it has been demonstrated that they possess a most manifest disinfectant and anti-putrid action.

In addition to the trials made with in the laboratory, it has been employed in the hospitals of Limoges. This agent has successfully purified the wards. It has also been used to preserve cadavers.

This ether offers another advantage; its odor is mild, agreeable, and entirely inoffensive.—*Monthly Review of Medicine and Surgery.*

## THE PHYSIOLOGICAL TREATMENT OF PNEUMONIA.

By J. TURNER EVERETT, A.M., M.D.,

SANDUSKY, O.

During the progress of the late animated and somewhat heated discussion of the subject of venesection as a therapeutic agent in the treatment of pneumonia there has been elicited many interesting and instructive facts. In all this correspondence nor in any text books which I have consulted has there been any mention made of a plan upon which I stumbled several years ago, and which, in my hands, has served the purpose of all the antipyretics, without any of their dangers, and which acts promptly and certainly upon the diseased tissues, without involving systemic or organic complications. Omitting all discussion of the etiology or pathology of pneumonia, or meandering among the myriad mythical distinctions of kind, type, and stage of invasion, I will at once give the particulars of what I have styled *my method;* for, although I have seen no mention made of this ideal in the literature, yet, the more one contemplates the simplicity and the rationality of the theory, the more one is struck with wonder that it had not been pursued centuries ago.

In nearly all tissues where the danger depends upon high temperature, and the consequent destruction of functional activity, the direct abstraction of heat has been the first step in therapeutics. This by the application of cold directly to the invaded part, or in its nearest possible neighborhood. Thus, in cerebritis, the ice-cap; in spinal congestion, ice-bags along the region of invasion, etc., *ad infinitum*.

It is universally conceded that the danger in pneumonia consists primarily in the pulmonic engorgement, and that the remedy lies in decreasing the blood-pressure in the tissues, either by reducing the force and frequency of the heart-beat, by lessening the contractility and tonicity of the vascular walls, or by decreasing the amount of blood in the general system.

All of these and each of them produce the same general result, only differing in the rapidity and certainty of action. If cold acts as a sedative and as an astringent upon capillary vessels, and as an abstracter of heat, why not apply cold directly to the seat of primary invasion in this as in other congestions? The truth of this proposition will doubtlessly be readily admitted, but the query will arise, how shall we apply a cold bath to the lungs? We cannot use cold compresses over the chest, for fear of increasing the congestion by driving the peripheral blood into the already engorged lung, neither is the general use of the cold bath advisable for the same reason. The solution of the difficulty, then, lies in applying the cold directly to the mucous surfaces of the air-passages of the lungs, to their finest and most distant ramifications, by *means of inhaling cold air continuously*. I say continuously, for the interrupted use of cold air, like an interrupted cold bath, would act as a stimulant instead of a sedative, and thereby augment the difficulty we seek to control. While the patient is inhaling the cold air, the temperature of which should range from 10° F. to 15° F., the room in which the patient lies should be kept at a temperature of from 80° to 85° F. Thus the afflux of blood is changed from the central organs to the peripheral. The cold air, coming in direct contact with the tissues of the pulmonic parenchyma, abstracts heat from the blood by coming in such

close contact with it over such an extensive area, being in the bronchioles, as you know, separated from actual contact only by the thin cells of the pavement or tessellated epithelium, where each globule of blood and atom of serum is subjected to a direct refrigerating influence, which can be observed and controlled with the most exact and satisfactory results. By carefully noting the external temperature and that of the patient, this abstraction of heat can be regulated with the utmost nicety and precision—can be commenced or stopped instantly, without prostrating the nervous system by sedatives or narcotics, and without the loss of blood.

This cold air in thus coming in contact with the lung-tissues causes contraction of the vessels, thus lessening the amount of blood admitted to the lung-tissues, and by its constringing influence tends to drive out that which has become partially deposited by the stasis, while by increasing the oxygenation of that already admitted it hastens resolution. The increased heat of the air surrounding the patient favors copious perspiration, thus, by the evaporative process, favoring the additional abstraction of heat. Of course, we must keep in view the fact that this agent, like venesection, veratrum, or any other antipyretic, would be useless after stasis occurs, and should therefore, like them, be used only during the stage of hyperæmia.

Fortunately for the more perfect employment of this remedy, Nature has provided us with a boundless supply, and as the great majority of the cases occur in the colder months, we have only to connect the lungs of our patient by means of an elastic tube, of sufficient calibre, with the external atmosphere, and we have the remedy in unlimited supply. In treating the few cases which might occur during the warmer months, the air should be drawn through a refrigerator. This being charged more or less with aqueous vapors, would not be quite so effective and pleasant as the clear, dry, cold air of winter, yet would serve a very useful purpose, and produce the same general effect.

Case I.—In December, 1877, was called to see Mrs. B——, who resided ten miles in the country. It was an intensely cold day, with snow driving fiercely from the northwest, the mercury standing six degrees below zero. As I approached the shanty, I wondered that people could live in such a habitation at all on such a day. Found Mrs. B——, a pale, anæmic woman, of thirty-eight years of age, lying upon a bed in the corner of the only room in the shanty, with the snow and wind surging furiously over and around her. Examination revealed the following symptoms: temperature, 105° F.; pulse, 135; respiration, 36 per minute; short, dry, hacking cough; no sputa; pain over left nipple; one cheek pale, while the other was suffused with a hectic flush; crepitant râles over lower half of left and third of right lung; dulness well defined. With these unfavorable symptoms and surroundings the prognosis could not be otherwise than grave. Left the following recipe, and promised to call the following morning:

℞. Ammon. chlorid..... ʒ ij.
Antimon. et pot. tart.. ..... grs. ij.
Morph. sulph..... grs. iij.
Tinct. verat. virid..... ♏ j.
Spts. etheris nitrosi..... ʒ iv.

M. S.—Teaspoonful every two hours in a little sweetened water.

Upon my return the following morning, found patient very much better than could have been expected. A roaring wood fire only served to modify a portion of the cold air which swept in with great violence through the many apertures.

Cases II. and III.—My attention was now called to a little girl and boy, aged respectively seven and eleven years, who were lying on the same bed with the mother, and who each had the almost pathognomonic dry, hacking cough of commencing pneumonia. Inquiry elicited the fact that they had both suffered from violent chills during the nights, which had been attributed to the intense cold weather; but the chill had in each case been followed by high fever in the morning. Auscultation revealed crepitant râles and percussion mapped out the exact amount of the invasion in each case. The short, hurried breathing, and the flushed cheeks, showed the intensity of the onset of the disease. These little patients were covered up as warmly as possible, and given the same remedies as the mother, but in modified doses. On my arrival the third day from the commencement of the sickness of the children, and the fourth day of the mother's sickness, to my surprise, found them all sitting up at the table, partaking, with apparent relish, of the ordinary foods.

The recovery of these patients was so rapid, uninterrupted, and unexpected, that I cast about for an explanation of the phenomena. Evidently it could not depend upon their extra hardihood engendered by exposure, for they were of a strumous diathesis, and rather below the average of poor, ill-nourished people, and the mother in particular, worn down by over-work, exposure, poor food, and excessive child-bearing, was extremely cachectic and anæmic.

Ruling out all other factors, the query arose, was it not the *cold air* which was continually admitted to the lungs of these patients, which had acted so profoundly, promptly, and beneficially in thus cutting short the grave symptoms of this disease. At this conclusion I at length arrived, and determined to test the truth of the theory upon the first opportunity.

Case IV.—A few weeks later, was called to see a patient—a plethoric son of the "Emerald Isle"—in the first stage of pneumonia, with the following symptoms: Pulse, 120; temperature, 103° F.; respiration, 22; flushed face and hacking cough, no sputa. Physical examination revealed dulness over middle third of right lobe of lung, with faint crepitant râles. Decided to test the theory in this typical case, I instructed his wife, a more than usually trustworthy and intelligent Irish woman, to keep the temperature of the room at 85° F., day and night, and to keep him covered with flannel sheets. At once procured a piece of one and one-fourth inch rubber tubing, several feet in length, and, boring a hole through the window sash at the head of his bed, inserted one end of the tube, while the other end, fitted with a proper face-piece, was given to the patient, with instructions to breathe only air from the external atmosphere, it being at 10° F.

Eight hours after completing this arrangement I returned, and found that although the only medicine which the patient had taken was a one per cent. solution of ammonic chloride, a teaspoonful every three hours, the temperature had fallen to 99.5° F.; the pulse was 76; and respiration 20. The face was pale and the body covered with a profuse perspiration. Dulness on percussion less distinctly marked and the crepitant râles changed to a moist vesicular murmur, audible during the expiratory as well as during the inspiratory act. Instructed the

nurses to pursue the same course of treatment, and left, promising to call next morning. Owing to unavoidable delay, did not see the patient till the afternoon, when I found him quite feverish, expectorating white viscid sputa slightly tinged with blood. I learned that at bedtime the previous night, patient had felt so much better that the nurses had been dismissed, and the wife had retired and allowed the patient to control his own inhalations of *cold air*, and that falling asleep the face-shield had become disarranged, and he had for some hours breathed the heated vitiated air of the sick room. Awakening near morning with a feeling of chilliness he had covered up more warmly, but had neglected to use the *cold air* tube until the fever again appeared, when he bethought himself of his carelessness and the tube was again brought into requisition.

The wife upon awakening and finding the patient in this condition, at once built up a hot fire, and on my arrival I found the patient much easier and less feverish than the condition in which they found him at sunrise. Advising them to be more careful in the future, directed a continuance of the same course until the next morning, unless symptoms should demand a change, in which case I was to be summoned at once. On visiting my patient the morning of the third day, found the temperature below the normal of health. Vesicular murmur clear over entire normal surface and no dulness. Pulse soft, skin moist, and patient comfortable.

From this time on the patient made rapid and perfect recovery. His only medication, strictly speaking, consisted of twenty grains of ammonic chloride in water, its administration extending over a period of seventy-two hours.

Case V.—Was called, January 3, 1879, to see C. W——, laborer, aged thirty-eight, full habit and ruddy complexion. Found him with temperature of 104° F.; pulse, 120, hard and bounding; respiration, 25, labored and accompanied by dry hacking cough. Considerable pain near right nipple, slight dulness on percussion and crepitant râles.

The chill had occurred early in the night, soon followed by a high fever. Prescribed the following:

℞. Ammonic chloride..... ʒ j.
Morphia sulph..... grs. ij.
Syrup glycerrhiza..... ℥ iv.

M. S.—Teaspoonful every hour until pain ceased and cough lessened and became more soft and moist.

I arranged the apparatus for the inhalation of *cold air*, the mercury standing outside at 0° F. The room was then heated to 85° F., and patient left with directions to continue treatment until the next visit. The following morning found the temperature had fallen to 98.5° F., the pulse soft and compressible, beating eighty to the minute. The respiration was still short, but painless, the dulness was circumscribed and the crepitant râles had changed to a moist rhonchus. Continued the same medication and directed patient to inspire warm air in combination with the cold, gradually lessening the amount of the cold until he breathed air at a temperature of from 65° to 70° F. On my next visit, the following morning, found patient sitting up and feeling very much better. From this time on patient made rapid and complete recovery, complete resolution being fully established by the tenth day from the onset of the disease.

Case VI.—On January 25, 1880, was called early in the morning to see Larry O——, laborer, aged forty-two, who had been working in a brewery and had "taken a heavy cold." Patient after a very hard day's work, and retiring very much fatigued and prostrated, had been awakened in the night by a chill; took some hot drink and retired again, but was soon in a raging fever. Found patient with flushed face, with high fever, short of breath, and making great complaint of the pain in the chest. Temperature, 102° F.; respiration, 28; pulse, 116. Dulness over lower half of right lung with crepitant râles. Ordered,

℞. Tr. veratrum viride..... ʒ j.
Tr. opii. camph..... ℥ ij.
Spir. ether. nitrosi..... ℥ ij.

M. S.—Teaspoonful every thirty minutes until fever subsided.

This family was so very stupid I did not dare rely upon the *cold air* bath, well knowing that no directions could be implicitly complied with.

Case VII.—On leaving the shanty of Larry O——, was called across the street to see Frederick H——, a German, who worked in the same brewery. I found him with same symptoms as his neighbor, but in an exaggerated form. Dulness over lower third of both lungs, crepitus distinct, shading off toward apex of left lung, cheeks livid, short, dry, hacking cough, accompanied by cutting pain over left nipple. Temperature, 105° F.; pulse, 130, and hard; respiration, 38. At once ordered the *cold air* bath for pulmonary vessels. External air at 0° F., and prescribed the following, viz.:

℞. Tr. opii..... ..... ʒ ij.
Ammonic chlor..... ʒ ij.
Syr. glycerrhiza..... ℥ iv.

M. S.—Teaspoonful every hour till cough and pain subsided.

The following morning visited patients, and found Larry O—— sweating profusely. Had suffered some nausea and great pain, and was exceedingly nervous. Temperature, 102° F.; pulse, 110, weak and intermittent. Dulness increased in area, and crepitant râles changed to coarse moist rhonchus wherever audible over the dull surface. Sputa tinged with blood and debris.

Ordered five-grain doses of quinine alternately with the previous medicine, and advised the free use of iced milk in place of the beer which they had prescribed for the patient. I crossed over to the house of Frederick H——, where I found him very much improved. Temperature, 101° F.; respiration, 20; and pulse 84, and compressible; face pale, and body moist, with copious perspiration. Continued same treatment, and ordered mild, unstimulating food, and increased the interval of the mixture to once in four hours. From this time on Fred made a rapid convalescence, which was fully completed by the twelfth day.

On the contrary, however, Larry O—— continued weak and anæmic, the pneumonic inflammation spreading to left lobe, and worked higher up in the right, culminating at the end of the first week in the suppurative stage, which left the lung in a bad condition, which still prevails.

Patient remained under my medical supervision for some time, and since resuming work has been confined with several attacks of lung trouble, there now remaining a large surface of dulness with contraction of thoracic walls.

Case VIII.—I was called, March 1, 1880, to see E. R——, a lady thirty-eight years of age, who had taken cold while hanging out clothes. The patient was a frail cachectic person, with hereditary predisposition

to phthisis. Was now complaining of pain in left mammary region, short, hacking cough, and cephalalgia. Temperature, 102.5° F; respiration, 24; pulse, 114. The external atmosphere being at 12° F., I ordered the flexible tube at once, and advised the temperature of the room to be kept at 85° F., and prescribed:

℞. Ammonic chloride..... grs. x.
Syr. glycerrhiza..... ʒ ij.

M. S.—Teaspoonful every two hours.

March 2d, 8 A.M.—Found patient easier. Respiration free and uncomplicated, 18 per minute; temperature, 99.5° F.; pulse, 100. Vesicular murmur fully established, and dulness nearly all gone. The temperature of the inspiration was gradually brought near the temperature of the room, which was allowed to run down to 70° F. From this time on patient improved rapidly, and made satisfactory recovery.

During the time occupied by these investigations, I had other cases of pneumonia, but from their complications and atypical character, they would not serve as good a purpose for clinical study as the above. In no case treated by venesection or by antipyretics have I seen such rapid, certain, and satisfactory results as by the *cold air* bath. These cases, I think, were not exceptionally favorable ones of mild type, but were of average severity, and the results could have resulted from no accidental circumstances, but, I believe, depended directly upon the sedative and contractile effects of the cold air upon the pulmonic tissues. I hope others will test this simple method, and that the result may be as satisfactory to them and their patients as it has been in my experience.

## DENTAL SOUND-TRANSMISSION—THE JAPANESE OTACOUSTIC FAN.*

By SAMUEL SEXTON, M.D.,
AURAL SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY.

MR. PRESIDENT AND GENTLEMEN: The increasing interest manifested in physiological acoustics by otologists during the past few years, has very much quickened the hopes of those who are in a measure cut off from the full benefits of life by impaired hearing; but, although the needs of the deaf have served to stimulate exertions in their behalf, the results attained have not as yet fully realized expectations.

For a long time the ear-trumpet, which simply increases the intensity of sound reaching the ear in the natural way, afforded the only practical means of aiding the defective sense of hearing; but this method has never been received with favor, most persons preferring to conceal their defects by avoiding the conspicuousness attending the use of a trumpet. The conversation-tube, which has been long employed, is of very considerable service for private use; but the deaf find that a great many object to placing their mouth to the aperture of a tube in general use.

Of late, however, it has been found that the teeth afford a valuable medium through which the sonorous vibrations of which sound is composed may be transmitted to the auditory nerve. It has been known for a very long time that musical tones may be heard by the deaf through the medium of a wooden rod connecting a musical instrument with the teeth; but such means were not found to be available for conversation. The dental transmission of speech by means of a vibrating fan has been frequently observed quite accidentally by persons who have placed the edge of a fan to the teeth while others were conversing; but it remained for Mr. Rhoades to make use of this fact in a practical way, by introducing a fan for conversational purposes. My earlier experiences with the audiphone were not encouraging, for it seemed that but few were willing to adopt them on account of their expensiveness, the advantages attending their use being apparently so limited. But now our Japanese friends, who are not slow in adopting useful discoveries from any source, have taken advantage of their great facilities for the production of all kinds of fans, to manufacture a sound-transmitting fan, the low price of which promises to bring it within the reach of all.

The first Japanese product came appropriately enough from the Lakujenqui Society's Institution for the Education of the Deaf and Dumb. It may be of interest, in this connection, to state that this society was organized some three years ago with Mr. Yamao, the Minister of Public Works, as President. Mr. Maye-Shimea, the Postmaster-General, is an active member of the Board of Trustees, as is also Mr. Yegawa Kimihira, the Japanese Consul to New York City, who is present this evening. The deaf and dumb institution founded by this society in Tokio three years ago, was the first of its kind to be established in Eastern Asia. It is free to the deaf and dumb from all parts of the empire, and is supported by the gifts of the founders and by voluntary contributions—their majesties, the Emperor and Empress, having given it their support. It is conducted entirely by the natives; the sign-language has only been taught as yet, although improvements in teaching will doubtless be made in the future.

It is the intention to make this institution self-supporting by the labor of its inmates, and I have the pleasure of showing you to-night the first products of their skill, which have recently been sent to this country by the society's president.

These sound-transmitting fans were placed in my hands soon after their arrival here, a few months ago, by Mr. Kimihira, that their merits might be tested, the trustees desiring to know if their construction is the best that our present knowledge of the subject can suggest, and, also, whether there is likely to be a demand for them in this country.

Having given these fans a careful trial, and finding that some of them - for there are several varieties—are more satisfactory than any sound-transmitting fan yet produced, and deeming them worthy of a further trial by the profession, I have presented them to the society, with some remarks on their use. I may here state that these fans are made of lacquered material; that they have several shapes, and are of different qualities, but not altogether unlike the audiphone, after which they were modelled. The lacquered sheets of which they are made, seem to answer the purpose even better than the vulcanite of which the audiphone is constructed; they are by far the more durable of the two, and much cheaper—the lowest in price being the best. They range in price from thirty-three cents up to three dollars each.

The method of using all sound-transmitting fans is similar: the fan is first bent upon itself so that its surface shall form a curve a little greater than the arc of an ellipse, but not quite equal to the arc of a circle, in which position it must be securely fixed

* A paper read before the Medical Society of the County of New York, June 26, 1881.

by attaching the cords coming from the superior border to a peg on the handle. The curvature should be unchanged while the fan is in use, else the person employing it, not feeling at ease, will fail to obtain its full advantages. During a protracted use of the fan the arm should have a rest, experience showing that those who require its aid are liable to become very nervous, and should not, therefore, have to think about keeping the fan in its place, etc.

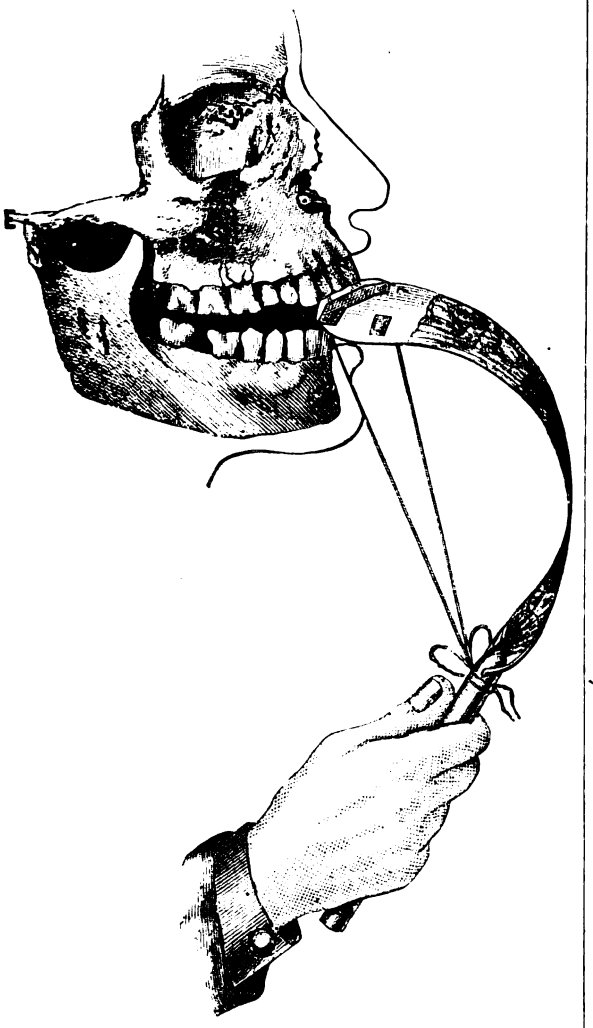

FIG. 1.—Lateral view of the fan when held in position for dental sound-transmission. The dental sound-transmitter, which is attached to the fan in the cut, is somewhat exaggerated in size, and its proper position between the canine and lateral incisor teeth of the upper jaw is not well shown. E. Location of entrance to external auditory meatus.

The fan, when bent as above described, is ready for use. The position of the fan, when its superior border has been placed against the teeth of the upper jaw, is very important. It should be held with its convex surface presenting to the speaker, who will be heard to the best advantage when directing his voice toward it.

Where the teeth are in good condition, the best results are obtained by placing the edge of the fan against either one, or both, of the superior canines, which are a little longer than the incisors, and thus offer the necessary resistance when the fan is pressed upward and backward. Contact with the teeth should be maintained by gentle and uninterrupted pressure while the fan is in use. Too much pressure against the teeth is to be avoided, a neglect of this precaution having resulted in loosening or otherwise injuring the teeth, especially when they are not in a healthy condition. Although the canine teeth afford the best medium for dental sound transmission, good results may be obtained from any of the upper teeth with which contact can be obtained. The teeth of the lower jaw and artificial teeth can be availed of to a limited extent only.

As regards the actual range of usefulness of dental sound-transmission, it may be said that its best results are obtained with those who are unable to hear the voice when shouted, say at a distance of ten feet; such individuals can usually hear words at that distance best with the trumpet, but when the speaker is removed only two or three feet from them, the fan affords the most assistance. The reason for this is apparent when the conditions are considered; for at the distance of ten feet the sound-waves are too feeble to cause effective vibrations of the fan, but they are collected and intensified by the trumpet. In either case the results are not very satisfactory: sound is, indeed, plainly heard, but definition, so to speak, is lost. When the speaker is near, however, the advantages of the fan are apparent; here the trumpet has a disagreeable resonance, while dental transmission, although imperfect, is more natural. The latter method, moreover, possesses an advantage that has not, to my knowledge, been accorded it—I allude to the bin-aural character of its action, the vibrations of sound passing to both ears at the same time.

Some individuals seem to be unable to acquire the use of either the fan or the trumpet. In one instance which I recall, the patient, a lady, could only hear conversation near by when the voice was raised to a loud tone; with the trumpet she could hear conversation when low, but its cumbrousness was an objection to its use. This lady heard ordinary conversation very plainly with the fan, but its metallic timbre was disagreeable, and the voice seemed to produce reverberations in her head; the more distinct my voice was, either by raising its pitch or by a nearer approach to the fan she was using, the more disagreeable it became. She concluded, from these experiments, that hearing in this disagreeable manner would be insupportable, and that it would make her very nervous.

Another patient, who uses the fan constantly, speaks of the nervous symptoms that arise from its use when he is unable to retain it in its proper position with ease, as in long conversations or at church. He can hear much better when not compelled to think about holding it in its proper position.

The fan's advantages, even in very great deafness, are shown in the case of a lady who can only hear words shouted into her ears. Conversation with the fan, however, at the distance of two feet, is readily carried on; at a greater distance, even, she is enabled to retain the thread of conversation, although some of the words may be lost. Like all very deaf persons, she gains much assistance by watching the speaker's lips, and when unable to do this, on account of the distance of the speaker—she is near-sighted—or the want of illumination, the fan is of much less service. By occupying a seat near the pulpit she has the satisfaction of hearing the minister very well. The trumpet aids her rather more than the fan, but she will not use it on any account.

Persons with normal hearing possess the requisite conditions to the perception of sound transmitted through the teeth to a limited extent only.

The *modus operandi* of dental sound-transmission is not unlike that of the normal ear, but it is far from being so delicate. The fan, like the membrana tympani, moves to and fro in response to aërial sound-waves, transmitting the impressions thus received to the teeth, and thence mainly through the intervening osseous tissues to the ear. The sounds that reach the auditory nerve in this manner are more or less modified as compared to normal transmission; the timbre is sometimes described as "metallic." Musical tones, however, seem to be most plainly heard.

FIG. 2.—The dental sound-transmitter is composed of a sheet of German-silver folded upon itself; the free edges are pressed apart to receive the upper edge of the fan. The edge opposite to the above, where the metal is folded, is turned up at an obtuse angle to fit the teeth. There are two holes in this edge for the attachment of the cords.

Osseous transmission is insufficient for the more delicate shades of speech; thus hissing sounds are generally suppressed. But notwithstanding its imperfections, the aid it offers to the deaf is of much service, and I have found many individuals who, by the use of a fan, enjoy a degree of hearing not otherwise obtainable. In these instances, however, the successful use of the fan has been only acquired by the observance of the laws which govern sound-transmission; such a course enables the patient to ascertain just what benefit may reasonably be expected from the method, and to thus avoid the nervousness and disappointment which so often arise from futile attempts to obtain results in their nature impracticable.

These conclusions are somewhat at variance with the opinions I formerly entertained on this subject, but my later experience seems to justify them.

The experiments that I have recently made with Japanese and other fans, have led me to devise a dental sound-transmitter which can be attached to almost any fan. It is so constructed that it may be readily slipped over the upper edge of the ordinary paper-covered bamboo fan, when, by means of the cords fastened to it, the fan may be bent over and secured ready for use. When not in use it can be carried in the pocket. The springiness of the two plates of the instrument is sufficient to retain it securely in its place on the fan. It consists of one piece of German-silver plate folded together, but leaving space enough to receive the edge of the fan between its free edges. The mouth-piece of the sound-transmitter is slightly turned up, which affords a more perfect adaptation to the teeth than the edge of a fan; it also protects the fan from moisture and from injury by the teeth. It is made by Mr. Ford, of Messrs. Caswell, Hazard & Co. It is nickel-plated.

By means of this instrument a great variety of fans become available for the transmission of sound; I have found the ordinary Japanese fan of commerce, which costs but five cents, to answer as well as any other, although not so durable as the Japanese otacoustic fan, which is the best for the use of gentlemen who wish to carry the fan about with them in a special pocket made on the inside of the skirt of the coat. A fan of medium size has been found more convenient than the larger ones.

*Conclusions.*—Dental transmission of sound, for conversational purposes, is of very considerable advantage to a large number of very deaf individuals. Its inconspicuousness gives it a decided advantage over the trumpet.

In most instances it does not convey as great a volume of sound to the ear as the trumpet, but, notwithstanding this fact, most patients prefer the fan. By either method general conversation cannot be well heard, the patient being compelled to confine his attention to one speaker at a time.

In adopting dental transmission as an aid to the impaired sense of hearing, the assistance of some one competent to give instructions respecting the best method of using the fan should be obtained.

And finally, only the limited amount of assistance should be promised which experience has shown to be practicable.

12 WEST THIRTY-FIFTH STREET.

### REPORTS OF PRACTICE AND PECULIARITIES OF TREATMENT.

BY W. H. DRAPER, M.D., ATTENDING PHYSICIAN.

#### CLINICAL REMARKS ON SCABIES.

GENTLEMEN: The patient whom I present to you to-day illustrates an interesting topic in dermatology.

We may divide diseases of the skin into those dependent upon an internal and those dependent upon an external cause. This distinction is of importance from a therapeutic point of view, and should always be borne well in mind when you meet with such diseases.

Here is a case which depends upon an external cause, and upon one of the most interesting external causes which give rise to skin disease. Such causes embrace all kinds of mechanical, physical, and chemical irritations, inclusive of the parasites which prey upon the human integument. When we come to examine these parasitic causes, we find that they are either of animal or vegetable origin. The cause of this man's trouble belongs to the former class. Those of you who have given any attention to the subject, know the principal divisions of animal parasites; they are pediculi, commonly known as lice, including the pediculus capitis, the pediculus corporis, and the pediculus pubis, pulices, or fleas, acari, or itch-parasites, and cimices lectularii, or bed-bugs. These are the four principal classes, each of which produces its special sort of irritation.

This is a case of scabies, a disease dependent upon the irritation caused by the acarus scabiei—an illustration of what is vulgarly known as the itch. Our patient has been complaining, for a number of days, of itching about the hands and wrists, and around the genital organs. These are the points of

election of the parasite in question. It prefers the delicate skin about the wrists, between the fingers, around the genital organs and ankles, and between the toes. Strange to say, the acarus scabiei never goes above the neck, although there is much tender epidermis in that locality; it also avoids the region of the shoulders. Another curious fact in its natural history is that the perpetrator of all the mischief is the female. The male is produced in small proportion as compared with the other sex, and is mainly obnoxious as a propagator of the species. It is the female that burrows in the skin, producing the peculiar eruption characteristic of the disease, while the male remains upon the surface.

Where the eruption is confined to the wrist or between the fingers and toes, you will see a characteristic form of vesicle. It may not be possible to discover many of these, because the patient, irritated by the intense itching of the vesicles, destroys them by scratching, leaving such an abrasion of the epidermis as you see here. The vesicle is small—not larger, perhaps, than a pin's head—and has running from it a cuniculus or canaliculus, at the bottom of which the insect is found. The vesicle represents the point at which the acarus entered, the cuniculus the long tunnel along which she burrowed her way to the softer epidermal cells, where she laid her eggs, and remained to complete her existence. In order to get at the acarus the vesicle should be opened with a needle, the instrument passed down to the bottom of the cuniculus, and the epidermis torn up. In this manner, you will be able to pick out, at the end of the furrow, a small, white, globular body, not larger than the finest grain of sand, but which, under the microscope, is found to be the parasite. One of the house physicians has picked a number of them out of this man's hand. The discovery of the animal in its nidus is the crucial test in the diagnosis, though the diagnosis can be made by those who are familiar with the disease, by the appearance of the vesicle and the seat of the eruption.

This disease is sometimes the source of an immense amount of suffering, and of an extent of lesion which is altogether disproportionate to the direct irritation of the parasite. The sensitiveness of the integument varies very greatly in different persons; what in one person would remain as a local disturbance, may in others produce general irritation, with an extensive lesion and great suffering. In some delicate, nervous, sensitive organizations, scabies may produce extreme eczema. It produces a degree of itching which is excessive. Scratching provokes hyperæmia, and hyperæmia may end in eczema. I have seen the body literally covered with scabs caused by the dermatitis, which patients have induced by scratching. Scabies therefore often becomes an exceedingly important malady—one which may give rise to an immense amount of trouble, and which no possible internal treatment will benefit.

There is one fact about this malady which is worth bearing in mind: all persons are not equally liable to this form of parasitic disease. Of two persons exposed, one man will acquire it; the other will not. Though the acarus fell upon the latter's hand, he will escape unaffected. This varying susceptibility is a striking feature in the history of diseases arising from animal or vegetable parasites. A parasite, vegetable or animal, in order to live and thrive, requires a proper soil, so to speak; it will not attack that which is not going to support it. This is a fact which is perfectly well recognized in the natural history of animal and vegetable organisms which live at the expense of the epidermis; it probably holds good also in regard to their analogues, the more recondite parasites, whatever these may be, which produce the exanthematous fevers. These diseases also presuppose a certain susceptibility: where this does not exist, no effects are produced; where it does, the effects are more or less modified by the degree of such susceptibility. Of two men exposed to small-pox, one may be stricken down with the malady, while the other remains untouched. The exanthematous fevers are by some supposed to depend upon the invasion of the body, through the skin or lungs, by certain species of fungi or bacteria.

The only rational treatment for this disease is an external treatment designed to destroy the acari. This is one of the diseases in which you may often gain great credit by a correct diagnosis. Scabies often passes for a more serious disorder. I have more than once known it to be mistaken for syphilis. I have seen its victims salivated with mercury, and the cutaneous irritation aggravated by iodide of potassium. Such blunders are by no means uncommon, and none better illustrate the evil consequences of error in diagnosis.

What is to be done for our patient? As the disease depends upon an external cause, an external remedy is indicated. Sulphur, which might be given internally from now till doomsday, without affecting the acarus, applied to the skin, destroys the parasite. Many substances have been used as parasiticides, but the most time-honored is sulphur, of which there are various methods of application. In the olden times of New England, a rather primitive process was resorted to. The patient was put into a barrel with his head sticking out, and there he was thoroughly fumigated. In these days we employ more exact and better procedures. The patient's skin is first softened in a bath; then, to soften it still more, he is rubbed down with soft soap. After being washed with soap and water and dried, he is rubbed everywhere with sulphur ointment. This application must be made to all parts of the body except the head and neck, not simply where the eruption exists; for, if it is confined to the seat of invasion, the treatment will probably fail. The wandering parasites, as well as those that are domiciled, must be killed—males, females, and ova must be destroyed. This necessitates a free opening of the pores by the use of soap and water, and a thorough application of the remedial agent to all parts of the body except those never visited by the acarus. The patient is then dressed in flannel, put to bed, and allowed to sleep till the next morning, when he washes and puts on clean clothing. Probably by this one application he will have been cured; but, to make assurance doubly sure, it is well to direct the patient to take this bath and employ the ointment for three nights. Strict directions as regards the clothing should be given, as the parasite may still linger there to attack the patient when he again puts on his garments. Wearing apparel should be fumigated with sulphur vapor, and thus be rendered safe.

This may seem an unimportant malady to students, but its victims look at it in quite a different light. It is certainly a disease worthy of attention, and the cure of a case which has resisted the treatment of other physicians, through an erroneous diagnosis, always confers a just credit upon the successful practitioner.

It is a curious fact in the history of this disease,

that, long before it was known to depend upon the presence of the acarus, a man by the name of LeGale, a medical student at Paris, asserted its parasitic origin, and claimed to have seen the parasite. He went from hospital to hospital and exhibited it. The matter was of such importance that it was brought before the Academy. His claims were investigated and he was found to be an impostor. The "parasites" were ascertained to be common cheese-mites, a number of which he carried around with him, deceiving people by legerdemain, asserting that these were the living organisms he had removed from the epidermis of the patient. After that it was discovered by some one, I think, in Corsica, that the malady really was due to a parasite, the common people there recognizing its dependence upon something that could be removed from the skin. Applying the microscopic test to this something, he came to the above conclusion, and asserted that LeGale had had the right idea, but had not been able to find the parasite. In France, to the present day, the disease is known as "la gale."

NOTE.—After the application of the treatment mentioned, the patient recovered.

# Progress of Medical Science.

RUPTURE OF THE UTERUS TREATED BY DRAINAGE—RECOVERY.—On March 26th, A. C——, a woman at full term, was brought into C. von Hecker's wards, in Munich, in a state of extreme collapse, with the objective signs of rupture of the uterus. The lower extremities of the fœtus could be felt immediately behind the abdominal parietes in the right hypochondriac region. On the left side the firmly contracted body of the uterus was felt, and just above it a soft mass was perceptible, evidently the placenta. Per vaginam, the fetal head was found just above the inferior strait. It was stated that previous to the arrival of the patient in the hospital the pains had been uncommonly strong, and had been further stimulated by the administration of ergot. At the time of admission, however, the uterine contractions had ceased, as is usually the case when rupture has taken place. The forceps was immediately applied, and three tractions sufficed to deliver the head, the rest of the body following quickly. Vaginal examination now disclosed a large rupture in the cervix, penetrating through all the coats; it was extensive enough to have admitted the passage of the hand into the peritoneal cavity. The fingers were introduced through the rent, following the umbilical cord to the placenta, which was situated on the left side, as previously diagnosed, and was readily extracted. The condition of the patient was not materially altered by these manipulations, so that stimulation was not resorted to. Next morning the abdomen became very painful and tympanitic, and vomiting of green fluid, which had been present previous to delivery, recurred. Accidental circumstances prevented the introduction of a drainage-tube until thirteen hours after delivery. When once in place, however, it gave exit to a considerable quantity of sanguinolent fluid, which continued to drain away slowly for some time. There were frequent calls to empty the bladder, so that the catheter was finally resorted to and enormous quantities of urine evacuated. During the next few days iced compresses and opium were sufficient to overcome the peritoneal irritation. There were profuse and fetid fecal evacuations, which seemed to exercise a favorable influence on the condition of the patient, but which caused the extrusion of the drainage-tube on March 30th. On reintroduction of the latter more sanguinolent fluid escaped, but the quantity rapidly decreased. The temperature did not rise above 38° C., and in two weeks the rupture was firmly cicatrized. The above case shows that drainage is the cardinal point in the treatment of rupture of the uterus, as the danger in these cases consists in the retention of septic fluids in the peritoneal cavity. Of late several successful cases have been reported in which the line of treatment pursued was essentially the same. In some of them the abdominal cavity was also washed out with antiseptic lotions, usually two per cent. solutions of carbolic acid. Among the advantages of this method of treatment are its simplicity and easy applicability, which recommend it to the country practitioner in whose practice such cases are especially apt to occur, because of the long time which often necessarily elapses before the services of a physician can be secured. If possible, however, irrigations of the peritoneal cavity with carbolized solutions should be dispensed with, as they are by no means free from danger.—*Centralblatt für Gynäkologie*, May 14, 1881.

APOMORPHIN IN DISEASES OF CHILDREN.—Impressed by the favorable reports published by Kormann with respect to the expectorant properties of apomorphin, Kushel tried this drug in seventeen cases of bronchitis and catarrhal pneumonia, in patients ranging from one-half up to ten years of age. There were eleven cases of bronchitis complicating measles, with high temperatures (up to 41° C.= 105.8° F.); one case of variola, with intense bronchial catarrh; two cases of catarrhal pneumonia; and, finally, three cases of obstinate bronchial catarrh with very tenacious sputa. In the last-mentioned cases muriate of ammonia and ipecac had previously been administered without loosening the cough; in the remaining cases apomorphin was given from the first. In a short time, usually within the first twenty-four hours, previously dry râles gave place to moist ones, expectoration was facilitated, and when fever was present the temperature sank. All of the patients got well. The remedy caused no vomiting and no interference with digestion. The method of administration and dosage was that recommended by Kormann (*Jahrbuch für Kinderheilkunde, N. F.*, vol. xv., p. 180). For an infant one year old, the single dose should not exceed 0.001 ($\frac{1}{60}$ gr.) every two hours, *i.e.*, about ten times a day; for every additional year up to eleven years a half-milligramme is to be added to the individual dose; after eleven years one milligramme. Thus:

| | |

M. D. in vitro cœruleo. S.—A teaspoonful every one to two hours, for a child of three years.—*Med.-chirurg. Rundschau*, April, 1881.

RESECTION OF TUMORS OF THE BONES OF THE SKULL AND OF THE MENINGES.—Langenbeck showed ("Proceedings of Congress of German Surgeons") a woman sixty years of age, upon whom he had thrice previously operated for the removal of an epithelioma situated over the right frontal protuberance. The patient presented herself for a fourth time this February, with

a recurrence of the disease in the same situation, of the size of the palm. During the subsequent operation, it was found necessary to remove a large piece of the frontal bone, as well as the underlying dura mater, with the exception of a small piece of the latter in the centre of the wound, where the growth had invaded the pia mater. It was intended to destroy this part with chloride of zinc at a later period. The wound was dressed antiseptically, omitting, however, the use of the spray, and the course of healing was perfectly aseptic. The diseased patch in the centre was thrown off spontaneously with a small amount of underlying cerebral tissue. No cerebral symptoms manifested themselves at any time, except a slight protrusion of the right eye. Langenbeck stated that he had performed a similar operation once before, while Genzmer had done several. Langenbeck recommended Esmarch's bandage in such cases, first enveloping the head with a gauze bandage, and then applying the constricting band around the forehead and occiput.

Endolaryngeal versus Extralaryngeal Operations.—Rose claims that certain intralaryngeal growths cannot be thoroughly extirpated except after fission of the larynx. After the operation, the parts may resume a perfectly normal condition, as shown by an anatomical preparation removed from a patient who died of typhoid twelve years after the surgical interference. Rose had performed thyreotomy on her for the removal of several infrachordal fibromata. Böcker, of Berlin, claims, however, that the so-called radical operation, *i.e.*, laryngo-fission, is not by any means always radical, even when the growths are simple papillomata or fibromata. He has even succeeded, by the endolaryngeal method with preceding tracheotomy, in establishing a permanent cure in two patients, one of whom had been once, the other repeatedly operated on by thyreotomy by competent surgeons. Moreover, the radical operation was more liable, even when successful, to lead to deformity of the larynx, with great impairment of its functions. Thus, in the first of the two above-mentioned patients, a large mass of indurated connective tissue was found, uniting the lateral half of the thyroid cartilage, separating the vocal cords widely at their points of insertion anteriorly, while the dislocation of the parts was such that the left vocal cord was situated opposite the right false cord. Still Böcker acknowledged that fissure of the larynx was necessary in some cases, and he had performed the operation himself.—*Proceedings of Tenth Congress of German Surgeons*, April, 1881.

Total Extirpation of the Urinary Bladder and Prostate Gland.—Gluck and Zeller have experimented on dogs and human cadavers with the object of ascertaining whether this operation is feasible or not, and have come to the following conclusions:

*First.*—Total extirpation of the prostate can only be performed with facility on the cadaver after resection of the pubic symphysis.

*Second.*—Extirpation of the bladder and prostate can be performed on man without opening the peritoneal cavity.

*Third.*—The cut ends of the ureters can be approximated and sewed to the urethra by means of an instrument which Gluck has invented.

*Fourth.*—Stitching the ureters to the rectum, so that the former opens into the latter, always gave unfavorable results in dogs, while the animals recovered when the ureters were led to the surface through the abdominal incision. The animals also recovered after the establishment of an artificial ectopy of the bladder, by stitching together the opposed anterior walls of the bladder and abdomen, and cutting through the adherent tissues at a later period.—*Proceedings of Tenth Congress of German Surgeons*, April, 1881.

Feculent Pyopneumothorax.—Tillmanns, of Leipzig, has had a case of this description under his care, which terminated favorably. The patient was a copyist of fifteen years, who had been seized by the arms and violently shaken, and developed, some time afterward, symptoms of pyopneumothorax. The pleural cavity was opened under antiseptic precautions, and its contents found to be feculent. It was very difficult to maintain the antiseptic treatment. Nevertheless, after the lapse of five months, the patient was discharged cured. Tillmanns believes that at the time of the shaking a perforation of the right flexure of the colon or of the duodenum resulted, with the formation of a subphrenic fecal abscess, the contents of which found their way into the pleural cavity through some of the muscular interstices of the diaphragm. Similar cases have been previously reported, occurring partly as the result of penetrating wounds, partly after perforation of healthy intestine (duodenum, colon, vermiform appendix), and occasionally from rupture of gangrenous diaphragmatic hernia.—*Proceedings of the Tenth Congress of German Surgeons.*

Treatment of Gonorrhœa by the Internal Administration of Chlorate of Potash.—Zeitlin (*Med.-chirurg. Rundschau*, May, 1881) has treated fourteen cases of uncomplicated urethritis with chlorate of potash, given internally in daily amounts of three grammes, as recommended by Dochman. The results have been uniformly favorable. After a few doses, pain and erections ceased, the discharge became less free and thinner, and a cure was soon obtained without the intervention of any of the disagreeable and serious symptoms (hæmoglobinuria, collapse, etc.), which of late have so frequently been attributed to chlorate of potash. The action of the remedy is due to its rapid excretion by the kidneys in an unchanged form, and its local effect upon the urethral mucous membrane. It may be remembered that the drug has also been used in the form of urethral injections, and has been given internally in cystitis, whether of gonorrhœal or other origin, with good results.

Acute Suppurative Prostatitis.—Beck, Surgeon-General of the Fourteenth German Army Corps, has never met with an instance of this affection resulting from external traumatism. In his experience, such cases have been due either to the retrograde extension of gonorrhœa, to the employment of excessively strong urethral injections, or they have occurred as complications of acute, febrile diseases, like typhoid fever, pneumonia, etc. (excluding cases which develop in pyæmia and tuberculosis). The disease is characterized by high fever, interference with defecation, frequent micturition, occasional retention of urine (due not so much to stenosis of the prostatic urethra as to spasm of the external sphincter vesicæ, the fibres of which interlace and are continuous with those of the prostate), painful enlargement of the prostate, etc. If seen at the beginning of the attack, the inflammation may be aborted by the application of leeches and ice to the perineum, the exhibition of cathartics and enemata, absolute rest, and, finally, the careful use of large-sized metallic

catheters, at proper intervals, so as to thoroughly evacuate the bladder, thus relieving the engorgement of the prostatic plexus of veins. When suppuration has set in, similar treatment should be resorted to, except that ice should be replaced by warm fomentations. The catheter should be used as before, since, besides relieving spasm of the bladder, it facilitates the escape of the pus into the urethra if the abscess be situated in the vicinity of this canal. If, however, the collection of pus be deep-seated, near the rectum, the course of the disease is more prolonged. If the process assume a destructive character, it is proper to make an incision through the rectum, although Beck himself has not found it necessary to resort to the knife.—*Betz's Memorabilien*, May 12, 1881.

Is the Decidual Cell Characteristic of Pregnancy?—Wyder claimed that the uterine mucous membrane possessed distinctly peculiar cells in each of the three states of menstruation, membranous dysmenorrhœa, and pregnancy. While the cells of the menstrual decidua were small (0.001—0.008 mm.) and spheroidal, and their interior almost wholly taken up by the nucleus, those of the decidua vera were large (0.02—0.05 mm.), and contained an excess of protoplasm, although the nucleus was also large. These statements, if well grounded, would be of great importance in cases of suspected pregnancy. Ruge, however, has found that, although decidual cells of the above description are, in general, indicative of pregnancy, they are not characteristic of this condition, or rather that cells are found in other states which are identical with decidual cells as regards size, shape, amount of protoplasm, the size of the nucleus, and general arrangement. Such cells were observed in cases of endometritis, especially when chronic and combined with metritis, and also in cases of membranous dysmenorrhœa. The sole difference between the decidua vera of pregnancy and membranes expelled in membranous dysmenorrhœa consists in the smaller size and greater thinness of the latter.—*Centralblatt für Gynäkologie*, No. 12, 1881.

Membranous Enteritis.—Dr. Francis W. Goss describes (*Boston Medical and Surgical Journal*, June 2, 1881) four cases of this affection, which is characterized by the discharge from the bowels of what appear to be membranes or skins, of varying size, in the form of shreds, strips, or tubes. This peculiar discharge is accompanied with uneasiness and discomfort, if not with actual pain. The malady is of long duration, the patients, during the weeks or months while suffering from the discharge, being invalids, often confined to the bed or house. They seldom so far recover as to be in robust health, and, sooner or later, are subjected to recurrences of the trouble, with the accompanying physical weakness and suffering. The patients are usually persons who have not enjoyed good health, but have for years suffered from headache, dyspepsia, constipation, and general debility. They are easily fatigued. Care or over-anxiety often precedes, and seems to bring on an attack. Rarely is there a single one, but there are commonly recurrences at intervals of months or years. The period of suffering may extend over many weeks, and during this time there are frequent discharges of the membrane-like substance, even several times a day. The paroxysms are commonly preceded by a febrile condition, nervousness, uneasiness in the stomach, and sometimes by nausea and vomiting. Abdominal pain and tenderness are not usually very marked, nor limited to any particular region, and the discharge is followed in some cases by a sense of relief. In the intervals between the recurrences of the attacks, the patients are rarely restored to vigorous health. The diagnosis can readily be established by a consideration of the clinical symptoms with an examination of the discharge. Such an investigation will eliminate intestinal worms, fragments of hydatids, intestinal diphtheria, dysentery, or the discharge of a portion of the bowel. Da Costa urges the importance of inquiring, in cases of anomalous nervous symptoms, particularly when happening in hysterical persons where there is abdominal pain, into the possible existence of the malady under discussion. The prognosis is rather unpromising for a complete recovery. The treatment during the paroxysm, or when one is threatening, resolves itself into putting the patient in the condition most favorable to mitigate or endure the attending discomfort. Many and varied, according to all authorities, have been the medicines employed to prevent the recurrence of the malady, but their results for the most part have been disappointing.

Removal of the Kidney for Nephrolithiasis.—Mr. Barwell recently removed a kidney from a boy fifteen years of age, suffering from pyelitis and retroperitoneal abscess (*London Lancet*, June 4, 1881). About ten months before the operation an incision had been made, and palliation following, the wound was allowed to close. A sinus had, however, remained, and in April a stone was detected by sounding. The patient was growing very anæmic, and developed hectic fever. At length an operation being consented to, lumbar nephrectomy was performed. The removal of the calculus was unusually difficult. This was owing, in part, to the presence of dense cicatricial tissue, but also to the proximity of the rib to the ileum. In the attempted removal of the stone, copious bleeding occurred, and it was therefore deemed advisable to remove the kidney along with the calculus. Since lack of room forbade removing the kidney entire, it was divided and extracted in two parts. A pedicle had been previously secured by ligature. The operation was then completed very quickly, and with only very little hemorrhage. The progress of the case after the operation has been in all respects a favorable one, the temperature becoming normal and the wound healing rapidly. It is now almost completely closed. This is the second successful case of extirpation of the kidney for stone.

Syphilitic Alterations of the Teeth.—M. Parrot has devoted several lectures to the description of these alterations, described by some authors as being of convulsive origin, and by others as of a rachitic nature, whilst the author regards them as one of the products of hereditary syphilis. The following is a brief outline of the argument used by him to enforce his position: The typical alteration is found in the first molar, where it is constant if existing in other parts of the mouth. The altered part seems free in the middle of the teeth, and appears on a lower level than the sound part, from which it is separated by a sort of furrow. It is yellow, of an ochrey aspect; the cuspids are more pointed and filled with small elevations like grains of sand, and extremely friable. On the other hand, the part of the tooth upon which these altered parts rest is normal, often covered as if with a coat of enamel. The peculiarity of this alteration is the sort of retraction which the tooth has undergone at

the same time, and which has given rise to the separation between the healthy and affected parts.

The cup-shaped atrophy, next described, may present itself alone or associated with other varieties. It is more particularly observed upon the upper middle incisors. The tooth is generally large and high, and on the anterior and posterior face are observed small depressions of varying numbers—from one to eight. Their diameter does not exceed one millimetre, and they are in a horizontal row, united by small grooves or separated by a fold of enamel. At their level the tooth is not enamelled; it is of a dirty yellow, and the dentine is often exposed. This form of atrophy is very remarkable, and seems to be the elementary form of other varieties.

The third form is the sulciform atrophy. It is rarely found in the molars; it occurs chiefly in the incisors, and consists in horizontal furrows in numbers from one to three—rarely four—always horizontal and parallel near the maxillary border. A fourth variety is a hatchet-shaped atrophy. This is observed in the first dentition, only in the incisors, and almost always in the superior middle. This alteration is not primitive, being produced after the complete development of the tooth, whilst the other forms described commence when the tooth is still in its sac. The fifth variety is that to which Hutchinson has called attention, consisting of notches, occurring chiefly in the superior middle incisors, but being also found in others.

All of these varieties may be more or less considerably modified, but are almost always accompanied by certain consecutive alterations. First of all is the color, which may be modified, even in very careful persons, becoming yellowish or even greenish. In those exposed to different dusts, these attach themselves to the surface of the teeth, and give rise to various colors. There is also an abundant deposit of tartar. By far the most important consequent alteration is caries. The molars are lost early, the jaw is atrophied, and spaces, as normally seen in horses, are soon established.

There are, however, changes in the teeth which must not be confounded with those described. Thus, at the second dentition, the incisors often present at their free edges saw-like notches; then it may occur that from friction the incisors may cut a bevel-edge on each other. The hatchet-shape may be determined by caries. And, again, there exist normally in some subjects true furrows. It is therefore necessary to be careful in making a diagnosis.—*St. Louis Medical and Surgical Journal*, July, 1881.

Cerebral Embolism. — Dr. Dickinson reports (*British Medical Journal*, May 21, 1881) two cases of cerebral embolism which were marked by their rapid course and the accompanying febrile symptoms. The two cases were similar in almost every particular. The subjects of both were girls; the leading symptoms in both were high fever and delirium, without any, or with scarcely any, definite paralysis, or the aphasia so common with cerebral embolism. The temperature in one case was always between 102° and 103° F.; in the others, generally between 103° and 105° F. In both there was decided evidence of pulmonary congestion with the progress of the disease, and rapid death by coma; with both there was a resemblance to meningitis, in the headache, the vomiting, and the mental disturbance; while in neither was there the constipation which is general, at least with the tubercular form of this inflammation. In both the resemblance to a specific fever, especially to typhoid, was superficially evident; but the fever was too high, and the cerebral embarrassment too great for so early a date in the course of that disease. The resemblance to an acute specific fever was very striking, and might have been misleading had the cases been observed hastily or in disregard of the concomitant circumstances. The pathological condition was, in a word, the distribution through the brain of embolic dust, which was so fine as to traverse, without hinderance, the larger arteries of the base and substance, to be finally arrested in the minute channels of the pia mater.

Nitrous Acid as a Disinfectant.—Dr. J. Lane Norris (*Dublin Journal of Medical Sciences*, June, 1881), in advocating aërial disinfectants, states that, as ordinarily practised in the sick-room, they are positively useless. To place carbolic acid, or permanganate of potassium in solution, in small quantities in a saucer in the corner of a room is utterly worthless, so far as any effect is concerned which is thereby produced on specific contagia, the quantity diffused being wholly inadequate to the object in view. Aërial disinfection, when resorted to, must be carried out in its minutest details, just as carefully as when we are dealing with liquid disinfectants, and the proportion of the agent used, and the size of the room it is proposed to submit to its action, carefully balanced, so as to ensure destruction of the poison. Of all the agents recommended, he found nitrous acid by far the most effective. The following experiment was repeated several times, and gave the same result each time: Two ounces of well-cleaned copper wire were treated with fifty cubic centimetres of concentrated nitric acid in a chamber with a cubic capacity of fifty-three feet, yielding, however, only 0.35 per cent. of nitrous acid. A saucer containing one hundred cubic centimetres of decomposing infusion of beef, full of active bacteria, was placed in the chamber with the nitric acid and copper-wire mixture, and the effect was most decided, reducing the activity of the bacteria, while the fluid was rendered strongly acid. The same preparation, after forty-eight hours, examined microscopically, showed still a diminished activity. The bacteria were largely precipitated, and the fluid was free from all putrefactive odor. The fluid in another test-saucer, on the other hand, was opaque and clouded with active bacteria, the putrefactive odor being very offensive. Examination on the third day showed still no tendency to the further development of bacteria, and the fluid remained quite inodorous. The test-saucer having been introduced into the chamber, with a further addition of thirty-five cubic centimetres of strong nitric acid, gave evidence of considerable improvement after the lapse of forty-eight hours, and, no doubt, would have been quite corrected by a further exposure to the nitrous acid fumes. Both these infusions, examined after the lapse of a week, showed changes for the worse.

These experiments, Dr. Norris is inclined to think, clearly prove that in nitrous acid we have a chemical agent which will arrest the development and further reproduction of septic microzymes, and which is therefore capable of destroying contagion.

---

The American Dermatological Association held its fifth annual session at Newport, August 30th, 31st, and September 1st. The meeting was opened by an address from the President, Dr. J. Nevins Hyde, of Chicago, "On the Relations of Dermatology to the Periodical Medical Press."

# THE MEDICAL RECORD:

## A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 10, 1881.

## THE RELATIVE POWERS OF THE DIFFERENT DISINFECTANTS.

THE difficulties in the way of accurately gauging the value of different disinfectants are much greater than would be supposed. It is not until within a few years that any satisfactory data upon this point have been obtained, and even now the question is far from being definitely settled. Over ten years ago Dr. John Dougall made some experiments upon the relative power of different reagents, to destroy infusoria and spermatozoa. Such substances as chloride of arsenic, corrosive sublimate, oxalic acid, and the mineral acids were found to be the most active in this direction. But the experiments were incomplete, and of little practical value. A short time after this, Dr. Calvert made some investigations, in order to determine what substances would longest prevent the development of infusoria, vibrios, and putrefactive odors in solutions of egg-albumen. He showed that carbolic and cresylic acids, chloride of zinc, corrosive sublimate, quinine, turpentine, and prussic acid were most efficient in doing this. But subsequent experiments have in a measure contradicted his results. Some years ago, Prof. Zürn and Dr. H. Endemann, of this city, made experiments with acetate of alumina, phenol, and salicylic acid. Their method was to add to a drop of putrid fluid containing bacteria, micrococci, spirilla, etc., a drop of water containing one of the above reagents in different proportions. The mixture was then examined under the microscope. Zürn's conclusions were that phenol dissolved in the proportion of one to two thousand, killed the organisms at once or in a few minutes. The organisms were considered killed, however, simply because they were made motionless. It was subsequently shown by Endemann that they were not really dead, and this experimenter made further and more elaborate investigations to test the power of various anti-zymotics. The results obtained by his method showed that cresylic acid will perfectly destroy bacteria, spirilla, etc., if it is contained in the fluid in the proportion of 1 part to 516. Carbolic acid will do the same if in the proportion of 1 to 278; salicylic acid in the proportion of 1 to 200, and hydrochloric acid if in the proportion of 1 to 64.

L. Buchholtz, of Dorpat, who has made similar experiments to those of Endemann, came to the conclusion that a larger proportion of carbolic acid (1 to 25, or 1 to 100), was necessary for perfect disinfection.

The above experiments were all made on the supposition that a destruction of the living organisms in a fluid destroys also its power to cause disease. Such a supposition is quite a legitimate one. For it seems very probable that even if bacteria and micrococci are not the special and direct causes of any disease, their existence is, in many cases, necessary to the development of the special poison.

The experiments which we have thus referred to have been supplemented by many others. But the subject has been by no means exhausted. We refer, therefore, with pleasure to some quite recent investigations by Dr. G. M. Sternberg, published in the *Bulletin of the National Board of Health*, which throw additional light upon the matter.

Dr. Sternberg's experiments differ from most previous ones in that he has used, as a test, vaccine virus and human saliva. As regards the former, the test of disinfection was, insertion of the disinfected virus into the arm of an unvaccinated child, virus from the same source not disinfected being inserted at the same time at a different point. A positive result from the non-disinfected virus and a negative result from that exposed to the disinfecting agent was taken as proof of the potency of this agent. The human saliva used was from the experimenter himself. He had found that this secretion, when injected into rabbits, produced a form of septicæmia, which was fatal in twenty-four hours. If such saliva, after treatment with a disinfectant, failed to produce any disturbance when injected, it was assumed that the virus of the disease was destroyed and that the disinfectant was a potent one.

In experiments with the vaccine virus, the conclusions were that chlorine, nitrous acid gas, and sulphurous acid gas were reliable disinfectants in the proportion of one volume to one hundred of air. That is to say, films of moist vaccine virus lose their power when exposed to air mixed with the above gases in the proportion given. It was shown also that sixty-eight pounds of pure carbolic acid, placed on the floor of a room twelve feet square and twelve feet high, would not kill bacteria in the room. This last experiment demonstrates what has indeed already long been known, that the sprinkling of carbolic acid about a room does not at all disinfect the air, but only the parts which the acid touches.

The experiments with the septic virus of human

saliva were made in order to test the power of non-gaseous disinfectants. The record of the various tests is somewhat long, but the results can be briefly summarized. The substances found to be disinfectant, are divided into three groups according to the amount of dilution necessary to destroy their efficiency.

The first group includes those efficient in the proportion of 0.5 per cent. Among these are iodine, thymol, and sodium hyposulphite. In the second group are those efficient in proportions below two per cent. Here we find carbolic and salicylic acid, chloride of zinc, permanganate of potash, and other substances. In the last group are those which failed to disinfect in a proportion of two per cent. These include eucalyptus globulus, salt, alcohol, camphor water, etc.

The experiments thus recorded, furnish an interesting addition to our knowledge of the powers possessed by different disinfectants. The last series, indeed, would hardly be of much value standing alone. But the first series is especially interesting as showing that disinfectants which kill bacteria will also destroy the particulate virus, whatever it may be, of those infectious diseases in which micrococci and their cousins are not found.

---

### THE ANNUAL MEETING OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE thirtieth annual meeting of this association was held at Cincinnati, and concluded its work the week before last. As it is a fair exponent of the general character of American science, its sessions always present something which deserves recording.

The recent meeting did not come up to the level of that of last year at Boston. The attendance was much smaller, and there was a notable absence of the older and better known men. Neither were there any striking addresses. It was noticeable that the younger men held the field, and did most of the work which, though in part light to the point of being trashy, yet, as a whole, showed industrious pursuit of knowledge and a love of it for its own sake. It is a hopeful sign for the future of science in this country, that the utilitarian spirit of the time has not yet put its mark entirely upon the younger scientific men.

The work in the biological and chemical sections, which would especially bear upon medical science, was tolerably good. Still we find few papers that were not rather too technical for general interest. A paper was read upon the "Life Unit of Plants," which consisted largely of re-statements. H. C. Hovey read an able essay entitled "Revision of the Anatomy of the Ethmoid Bone in Mammalia," which would be of interest chiefly to medical students, for they alone, we fear, of the medical profession are familiar with that complicated anatomical landmark. A paper of interest to comparative anatomists was one entitled "The Mesal Cusp in a Cat's Canine." Professor W. H. Brewer read a paper on "Color Markings in Domestic Animals," which showed some original observations. He had found that white feet, white spots, and other white markings occurred much more frequently on the left than on the right side in domestic animals. So far as he had studied, this law applied to the wild animals also. His inference was that the nutritive centres which regulate the deposit of pigment on the left side are weaker. In the Chemical Section, H. B. Parsons advocated the use of dry American wines, as preferable to the uncertainties of foreign importation.

There has been much claimed for synthetic chemistry in the construction of chemical substances; a paper upon the "Limited Biological Importance of Synthetic Achievements in Chemistry" has some interest, therefore. Prof. W. O. Atwater, in an essay on the "Source of Nitrogen in Plants," showed that they take it up to some extent from the air, and in this way obtain part of that material for growth. Mr. D. W. Prentiss claimed that the internal and external use of pilocarpin darkened the color of the hair, and even, in some cases, that of the eye.

The association did a useful thing in making a formal protest against the practice among American colleges of granting the degree of "Ph.D." *honoris causa*. Such a degree should indicate some attainments on the part of its possessor, but we can hardly say now that it does. The trouble is, however, not only that it is given "for honor," but also for a very insufficient amount of actual study and work. It is, we fear, beyond the power of the American Association to secure reform here.

---

### THE PRESIDENT.

AT date of writing the President has just been removed to Long Branch. The absolute necessity of getting him away from the intense heat and malarious influences of Washington had become apparent, and this necessity will justify the courage and boldness of the physicians in advising and carrying out the move, whatever the ultimate result. As yet it seems to have done no harm, but it will be several days before definite knowledge regarding the effect of the change can be gained. The climate of Long Branch is not of the most favorable kind, in the experience of New York physicians. It is very changeable, and is of course quite damp. Still, it is an improvement upon that of Washington.

In looking over the bulletins of the past week it is not easy to get much encouragement. The pulse is distinctly faster than a week ago, the temperature a degree higher, and respiration somewhat more rapid. The bulletins reported for five days "no material change;" for two days "some improvement." From these it would be inferred that the patient was on

the whole a little better; but the record of the pulse and thermometer do not confirm this inference. The heart has now been beating at the rate of about one hundred times per minute for nearly ten weeks. While no faster now than it has been at other times, there seems to be an increasing tendency to fluctuation, showing an irritable and weakened condition. The septic poisoning undoubtedly still exists.

The following table gives the range of the pulse during the successive weeks, and will show how steadily it has kept above the normal:

| | | | |
|---|---|---|---|
| 1st week | 100 to 120 | 6th week | 104 to 110 |
| 2d " | 98 " 108 | 7th " | 106 " 130 |
| 3d " | 96 " 130 | 8th " | 106 " 125 |
| 4th " | 76 " 118 | 9th " | 100 " 109 |
| 5th " | 96 " 104 | 10th " | 102 " 114 |

Little has been said in the bulletins about the condition of the wound, but it is to be inferred that there is no marked change in it. The bullet continues to cause disturbance, and is not yet encysted. The suppuration of the parotid gland has been improving, which is a most favorable sign. The stomach has also continued to hold out well, vomiting having occurred only twice during the week.

There is some just complaint regarding the meagre character of the bulletins. They furnish scarcely anything upon which medical men can base an intelligent opinion. We have no facts regarding the skin, tongue, excreta, facies, bodily weight, character of the pulse, nor even whether the temperature given is that of mouth, axilla, or rectum. It would be quite possible for the attending physicians to be more explicit and satisfactory in their official announcements.

### THE CASE OF JENNIE CRAMER.

The case of Jennie Cramer, an unfortunate girl, who was seduced, and, it is thought, murdered, near New Haven, Conn., has excited a great deal of comment and attention. The suspicious circumstances surrounding her death led to a prolonged examination of witnesses, and to securing a chemical analysis of her body. From the latter it was found that it contained about two grains of arsenic, distributed throughout the different tissues. The coroner's jury, therefore, brought in a verdict of death by violence, and an indictment has been drawn up against the supposed murderer.

The case will in time be brought to trial; meanwhile, the performances of the coroner's jury are what we wish to criticise. No case has ever brought out more clearly than did this one the folly of having non-experts on a coroner's jury. The entire conduct of the case was marked by delays and exhibitions of stupidity and ignorance, which brought down the censures of every one. The need of medical coroners, or of some such system as that adopted in Massachusetts, has been strikingly shown, and the people ought to profit by the experience.

## Reviews and Notices of Books.

Anatomical Studies upon Brains of Criminals: A Contribution to Anthropology, Medicine, Jurisprudence and Psychology. By Moriz Benedikt, Professor at Vienna. Translated from the German by E. P. Fowler, M.D. New York: Wm. Wood & Co. 1881.

Criminals are defined by the author as persons in whom there is an inability to restrain themselves from the repetition of a crime, notwithstanding a full appreciation of the superior power of the law (society), and a lack of the sentiment of wrong, though with a clear perception of it.

The author has endeavored to show that the brains of this class exhibit a deviation from the normal type, and that criminals are to be viewed as an anthropological variety of their species, at least among the cultured races. The deviation which Benedikt believes to exist, is that of a deficiency in the annectants of the different convolutions. In other words, these various convolutions are not so closely connected together; there are fewer associating fibres and more sulci. The cerebellum, in addition, is not, on the whole, so well covered as in normal brains, and the general course of the convolutions shows the brain to resemble more closely a lower animal type.

The number of cases on which these deductions are based, is twenty-two, the criminals being of various nationalities, but chiefly Sclavonic.

If such a conclusion as that which the author draws were sustained, it would be plainly one of the greatest importance. We cannot consider, however, that it is at all proven. The brains examined are too few, and the various factors of race and general physical development have to be considered. Besides, the investigations of Broca contradict in many particulars those of Benedikt, who, himself, has not the best reputation for mental equipoise. Furthermore, if we mistake not, the same atypy found here in criminals has been observed in the non-criminal.

Much more work must be done before conclusions upon this matter can be reached. And for our part we are very skeptical of the discovery of any anatomical basis of criminality. Certainly there would be no *à priori* reason to believe in Benedikt's theory, for some of the best developed minds (and, presumably, brains) show, not infrequently, a lack of the moral sense.

It is but justice to the author to say that he appreciates the incompleteness of his study and offers the work, in large part, as an incentive to further investigation in the same direction. The illustrations are numerous, but are not very good.

The translation is well and conscientiously done, though the translator has plainly given himself over to the theory propounded in the book.

American Nervousness: Its Causes and Consequences. By George M. Beard, A.M., M.D. New York: G. P. Putnam's Sons. 1881.

The medical reader will find in this work very much that which has already been published in various forms by the author. His views upon the subject treated are here, however, collected and systematized. The author believes that the peculiar life of the American people has resulted in the production of a widespread nervous exhaustion. This shows itself

in the great prevalence of the nervous diathesis, of neurasthenia, inebriety, insanity, and epilepsy.

We have not space to analyze the work, and it is, indeed, scarcely necessary. It strikes us, in the first place, that the author is fundamentally wrong in defining nervousness as a lack of nerve-force. Few will believe that all of the many nervous men and women met with daily in this country have any such deficiency. In many cases the typically nervous are so because their nervous system is developed to excess. There is too much nerve and too little muscle, bone, and fat. The body lacks equipoise of forces rather than nerve-force.

But, whatever the pathology, the fact that a widespread nervousness, peculiar in many of its features, exists in this country cannot be gainsaid. The present work is a most admirable exposition of the subject, showing, as it does, original thought and research, as well as much shrewd observation.

Dr. Beard is an author whose works, as a rule, contain a mixture of the very good and the very bad. For this reason, he is often condemned and praised unjustly. His most glaring fault — that of looking at things in general, including himself, in a most exaggerated light—is much less conspicuous in the present volume than usual. There are the evidences here of a broad and logical mind, as well as of extensive research and observation. We would not class the author, as he himself sometimes seems inclined to do, with Copernicus, Newton, and Darwin, because he discovered and organized American nervousness; but it would be injustice not to ascribe real originality to him, and equally unjust not to bestow high praise on the philosophical manner in which the present subject is treated. And one may look in vain through modern medical literature for better specimens of what may be called "fine writing."

PROCEEDINGS OF THE LOUISIANA STATE MEDICAL ASSOCIATION. New Orleans: I. S. Rivers. 1880.

ONE hundred and eleven pages are filled by the usual matter composing State Society reports. The president's annual address is a very satisfactory production, and there are also a number of very readable papers on various medical topics, so that this report, although small, is by no means an insignificant contribution to the general literature of medical society proceedings.

TRANSACTIONS OF THE STATE MEDICAL SOCIETY OF WISCONSIN. Milwaukee. 1880.

THIS volume is not the receptacle of abundant papers with profuse records of cases, but it contains a few good reports on practical matters relating to medicine. There are only eleven papers, all told, and yet the volume compares favorably with other transactions of a similar kind. The general outfit is also above the average of "State Society Proceedings" books. Excellent paper and an equally good typography render the general appearance of the Wisconsin volume very attractive.

THIRD ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF THE STATE OF CONNECTICUT, for the fiscal year ending November 30, 1880. Printed by order of the Legislature. Hartford, Conn. 1881.

THIS is a volume of more than usual interest, containing a great abundance of useful information, both local and general. There are papers of special significance on typhoid fever and sewerage. A report on the transmission of tuberculosis from the meat and milk of infected animals, by Dr. Cressy, forms a timely contribution to that department of pathology. Another paper on color-blindness, by Dr. W. T. Bacon, is also of great interest, although it is rather incomplete in some of its details.

THE STUDENT'S MANUAL OF HISTOLOGY, FOR THE USE OF STUDENTS, PRACTITIONERS, AND MICROSCOPISTS. By CHARLES H. STOWELL, M.D., Assistant Professor of Physiology and Histology, etc., University of Michigan. Detroit: George S. Davis. 1881.

THIS manual is intended for students merely, and is in all respects the most unsatisfactory production of the kind which it has yet been our fortune to behold. Those drawings which are not copied are wretched, and will confuse rather than instruct the student. The reproduced cuts are also for the most part worse than poor. As regards the text, it is inadequate to give beginners even a fundamental knowledge of the facts of histology. Some parts are unduly expanded, others so pathologically contracted that brevity ceases to be a merit. Still others have no existence at all. To mention only one such item, not a word is said in the whole book about the mammary gland, an organ which has excited, and continues to excite, the interest and attentive consideration of both histologists and pathologists.

The inevitable school-boy chapter on tumors, apart from being utterly out of place in a book purporting to treat of histology, is intrinsically so wretchedly poor, that no work on pathology would care to be disgraced by embodying such an account of neoplasms in its pages.

A TREATISE ON BRIGHT'S DISEASE AND DIABETES, WITH ESPECIAL REFERENCE TO PATHOLOGY AND THERAPEUTICS. By JAMES TYSON, A.M., M.D., Professor of General Pathology and Morbid Anatomy in the University of Pennsylvania. Including a Section on Retinitis in Bright's Disease, by WILLIAM F. NORRIS, A.M., M.D. 8vo, pp. 312. Philadelphia: Lindsay & Blakiston. 1881.

THE author of "The Cell Doctrine" and a "Guide to the Examination of Urine" has written a new book, which is not a new book. In other words, the pages of this volume will be searched in vain for the evidences of original research or special investigation. Still, as Dr. Tyson tells us in his preface that "for more than fifteen years his thoughts and studies have been in the direction suggested by these subjects," we may suppose him to be well qualified to furnish us a satisfactory résumé of our present knowledge concerning them. And in this we are not mistaken.

The physician who desires to know what modern renal pathology signifies, and what a system of rational therapeutics based thereon means, may be cheerfully recommended to procure the present book. Dr. Tyson has wisely abstained from entering into the details of pending controversies in regard to certain vexed points connected with Bright's disease and diabetes.

He gives us in compact form what are to be considered facts of renal pathology and therapeutics. As regards treatment, however, we can hardly say that the author has been merely a compiler of other's views. In fact his personal experience in this direction appears to have been somewhat exceptional. In diabetes, for example, the first agent mentioned under the head of medicinal treatment is ergot. This drug he gives first, not because it is invariably useful, but because he has "been able to trace to it results more directly than to any other

remedy." The majority of those who have tried ergot have failed to become impressed with its utility in saccharine diabetes. Dr. Norris's chapter, while it presents nothing which the profession does not already know, will be found to contain a concise and carefully prepared recapitulation on the subject of retinitis in Bright's disease. The mechanical execution of the volume is creditable to the publishers, but the colored plate illustrating waxy casts is a poor production, and should have been entirely omitted.

SUPPLEMENT TO ZIEMSSEN'S CYCLOPÆDIA OF THE PRACTICE OF MEDICINE. Edited by GEORGE L. PEABODY, M.D., Instructor in Pathology and Practice of Medicine, College of Physicians and Surgeons, New York; Pathologist and Medical Registrar to the New York Hospital. Pp. 844. New York: Wm. Wood & Co. 1881.

IT was a keen sense of the value of so comprehensive and thorough a work as "Ziemssen's Cyclopædia" which prompted the issue of the present supplementary volume. According to the editor, its immediate object was to remove from that great storehouse of medical knowledge, the Cyclopædia, "the few traces of time that the last few years have produced." But the book really does more than this. It truly supplements the volumes of the Cyclopædia by recording, in brief form, the advances of medicine with special reference to the subjects treated of in the main work. In addition, however, and quite independently of the original work, it gives a résumé of the general progress achieved in our profession during the past five or six years, and it supplies a copious and in most instances carefully selected bibliography of modern medicine. The circumstance that all the contributors to this volume are American physicians, and not a few of them eminent writers in their special departments, will go far toward making the book doubly welcome to the American reader. In fact we need not hesitate to say that it forms an almost indispensable companion to the previous volumes of the Cyclopædia, and thus becomes a supplement in the best sense of the word.

The amount of labor requisite to edit such a volume in a manner which even approximates to uniformity in the treatment of the different subjects, must have been very great. Accordingly, we are not warranted in feeling surprised at the absence of Dr. Peabody's name from the list of contributors. The twenty-eight gentlemen who have furnished articles, are more or less representative physicians, living in various parts of the country. It would appear that the space assigned to some subjects has been rather too limited, while other chapters are characterized by some unnecessary expansiveness. But perhaps such defects are not altogether avoidable in a work of this kind.

Not the least valuable feature of this supplement is, as already intimated, the copious bibliography with which most articles are provided. Indeed, some of the contributions seem almost like an *index medicus*, mitigated by an occasional explanatory remark or suggestion from the contributor. On the other hand, some chapters excel in a conspicuous absence of complete bibliographical indices. And notably one very able contribution, which bears the stamp of some pleasing originality, is totally divorced from all bibliography. We refer to the article on syphilis by Dr. Hyde, of Chicago. The bibliography was omitted, the editor informs us, for lack of space. We had rather missed the text of the unsatisfactory, because much too brief, contributions relating to myalgia rheumatica, corpulence, idiopathic adenitis, diabetes insipidus, erysipelas, and the diseases of the spinal cord, than the bibliography of the chapter on syphilis.

Diphtheria is discussed twice. The first time in a special chapter together with croup, and again under diseases of the pharynx. Of course such a double representation is not necessary, even when the disease has the great practical importance which diphtheria undoubtedly possesses.

We have pointed out what we considered defects in the preparation of the volume before us, because we would like to see them remedied in future editions. In conclusion, we can only repeat what we expressed at the outset of this brief notice, viz.: in our opinion the book *per se* forms a desirable acquisition to the physician's library, and an almost indispensable supplement to the possessor of "Ziemssen's Cyclopædia."

ANATOMICAL PLATES ARRANGED AS A COMPANION VOLUME FOR "THE ESSENTIALS OF ANATOMY," AND FOR ALL WORKS UPON DESCRIPTIVE ANATOMY, COMPRISING FOUR HUNDRED AND THIRTY-NINE DESIGNS ON STEEL, ETC. Edited, with Revisions, from the Original Translation of Prof. Pattison, by AMBROSE L. RANNEY, A.M., M.D., Adjunct Professor of Anatomy in the Medical Department of the University of the City of New York, etc. New York: G. P. Putnam's Sons. 1881.

THE present atlas is an almost complete reproduction of Dr. Pattison's translation of Masse's work. Both editor and publisher appear to have become aware of this fact rather "late in the season," for on the title-page Dr. Ranney's name still shines resplendent in conspicuous type, although our copy shows a lead-pencil addition, setting forth that he has edited the work "with revisions" from the original translation of Pattison. Masse's name is not even alluded to, except in an accompanying note from the publishers, which ascribes these trifling omissions to "a clerical error." We were not previously aware of the full meaning and wide scope of this expression, but in our present enlightened condition we are prepared to state that the terms are but a convenient synonym for almost unmitigated plagiarism. We say almost unmitigated, because Dr. Ranney's insignificant changes and additions, some of them even very poor ones at that, will fail to convince the reader that the present self-styled editor deserves to have his name paraded on the title-page at all. Judged merely by itself, Masse's Atlas is not above the average of works of its kind. The plates are not superior productions of skilled art, nor, on the other hand, have they the diagrammatic clearness and simplicity of less pretentious designs. However, the atlas is cheap, and that is about its sole recommendation.

DYSPEPSIA: HOW TO AVOID IT. By JOSEPH F. EDWARDS, M.D. Author of "How a Person Threatened or Afflicted with Bright's Disease Ought to Live," "Constipation Plainly Treated," etc. Presley Blakiston, Philadelphia.

A PLEASANTLY written treatise, containing much information for the careful and timid eater. The author inveighs against overfeeding, and lays down the axiom that the flesh eating people out-fight and out-work the vegetarians. Moderation and regularity are, of course, enjoined. Many useful hints make the work thoroughly practical, and its freedom

from technicalities cannot fail to render it popular. A recommended perusal on the part of the physician to his dyspeptic patient will save much time and many words.

A New Form of Nervous Disease: together with an Essay on Erythroxylon Coca. By W. S. Searle, A.M., M.D. 8vo, pp. 138. New York: Fords, Howard & Hulbert. 1881.

The number of new forms of nervous diseases is increasing with most interesting rapidity, and the list is already a long one. Myxœdema has for some time been established as a distinct pathological entity. Neurasthenia has been making the loudest possible claims upon medical attention. Gout, we are now informed, has a neurotic origin; the same is sometimes true of diabetes. Fatty heart, according to Kennedy, is often due originally to pathological changes in the trophic centres. There is much evidence that leprosy is a nervous disease. La Salpêtrière has furnished some very novel nervous phenomena.

But there have been few observers who have come out with so bold a claim for a new form of nervous disease as has been done by a homœopathic practitioner of this city. Our Hahnemannian brethren are just beginning, so it seems, to study medicine seriously. Their efforts are characterized, as a rule, by a pleasing enthusiasm and freshness of style, which in part compensates for the load of mental equipoise and the rather narrow range of knowledge displayed. The reader feels sure that by and by they will know more and do better. Thus we have in the little work of Dr. Searle's, a very interesting and earnestly written book. The observations it contains are well made, and the work is a contribution to medicine of real value. There are, however, two objections to it which are fundamental. The author attempts to construct a new disease out of some twenty or thirty cases, and he announces as new, and never before published, what has been as well, or better, described by Weir Mitchell some six years ago.

This "new form of nervous disease," announced by Dr. Searle, is characterized by two phenomena: a sensation of sudden shock or blow, or explosion in the head, usually accompanied with vertigo, and a condition of passive congestion, usually of the cerebellum only.

The symptoms as occurring in one of his patients, a man, aged forty-seven, were as follows: About daylight the patient was suddenly aroused from profound sleep by a sudden shock in the occiput, accompanied and followed by vertigo, which was very severe. He sprang up and fell over upon the bed, not losing consciousness however. The experience repeated itself five or six times before rising. During the day a sense of dulness, weight, and confusion oppressed the head, especially in the occipital region.

In this and in other cases the shock was found to occur at varying periods. In the intervals, the symptoms of cerebral congestion were often prominent. In one case only, consciousness was lost. The patient never had epilepsy, nor was there any history of that disease in the family.

Such are the principal symptoms as given by the author. Essentially the same phenomena are described by Mitchell in a little work on nervous diseases recently published. Dr. Mitchell first described them in 1875 in the *Virginia Medical Monthly*.

In his book the symptoms are classed under the head of "disorders of sleep." Mitchell finds them occurring quite often in hysterical women, and appearing generally at the time of dropping off to sleep, being a kind of nocturnal "fish-flap." They are undoubtedly akin to the sudden starts which many healthy individuals experience when dozing, and which sometimes arouse the person as completely as if struck by a blow. The difference, at least, must be one of degree rather than of kind.

The same symptoms have been observed by many others, and the matter was discussed briefly at the meeting of the American Neurological Association two years ago. Dr. Searle has got hold of some of the most highly developed cases. A wider clinical experience, and a more extensive knowledge of the literature of the subject, would probably lead him to modify his views.

Lectures on Diseases of the Nervous System, Especially in Women. By S. Weir Mitchell, M.D. With Five Plates. 8vo, pp. 238. Philadelphia: Henry C. Lea's Son & Co. 1881.

Dr. Mitchell's contributions to medical literature never fail to contain new observations, or to show the work of a broad and original thinker. The present small volume, though unpretentious, is entirely worthy of its author, and is one of the most entertaining and readable treatises we have met with for a long time.

The class of diseases which is discussed, is that which has hysteria and neurasthenia for its basis. In thirteen lectures the author describes the various subdivisions to which the many symptoms developing upon such soil may be assigned. It is impossible, in the space we have, to give any adequate analysis of these chapters, but we may briefly refer to those phases of the hysteric or neurasthenic diathesis of which Dr. Mitchell may be considered the first discoverer, or at least the first describer. Under the head of hysterical paralysis he describes a form of hysterical motor ataxy different from that mentioned by Briquet and Leségue, and first noted by the author himself. In a chapter on spasmodic affections in women, he relates the histories of several cases of hysterical athetosis. There are also two chapters on chorea, which give the result of extended researches into the meteorological relations of that disease. The results obtained are not very definite, but seem to show that chorea has, like neuralgia, some relation to storm-centres. Under the head of disorders of sleep, he describes the symptoms of shocks or explosions in the head, with accompanying nervous disturbances, all of which have recently been announced by a physician in this city to constitute "a new form of nervous disease."

In two chapters on mimicry in disease, the author gives us some rather old stories; and his views on this particular subject would be much broadened by a knowledge of the phenomena of hypnotism, recently studied with so much activity.

We turn with especial interest to the concluding chapter, in which the author discusses again his well-known "fat and blood" treatment of neurasthenia and hysteria. Dr. Mitchell still claims for it the very best results, and feels even greater confidence in its usefulness. We note, however, at the end that the author carefully guards himself. He would, he says, resort to this treatment only after exercise, out-door life, tonics, or change have been carefully tested. Again, as to the permanence of his cures, which has of late been much questioned, he makes the somewhat vague statement that they

"are quite as lasting as the cures of any nutritive defects obtained in more ordinary ways."

The work does not treat of the hystero-epilepsies, hysterical contractures, etc., described so fully by Charcot and others. Dr. Mitchell expresses the generally accepted opinion of neurologists when he says that these diseases are very rare indeed in America. The subject of the modification of functional nervous diseases in different races, and in different modes of life, is thus touched upon, but is not discussed.

The work, as a whole, treats of its special subject in an admirable and philosophical manner. It has only to be remembered that, after all, these curious phases of disease are not met with often, and to most practitioners they cannot have a great practical interest.

We cannot forbear, in conclusion, to commend one thing, and that is the absence of drugs and specifics in treatment. Tonics are almost the only medicines referred to, and a system of "building up" is at the basis of all the therapeutics.

THE DISEASES OF CHILDREN: A PRACTICAL AND SYSTEMATIC WORK FOR PRACTITIONERS AND STUDENTS. By WILLIAM HENRY DAY, M.D. Second Edition. Rewritten and Much Enlarged. 8vo, pp. 744. Philadelphia: Presley Blakiston. 1881.

THIS work, which has already been before the profession, does not need an extended notice now. It is, as it claims to be, practical and systematic. There is but little pathology in it, and the author's views on mooted pathological points, such as the difference between croup and diphtheria, etc., are not worth much. The work is essentially a clinical one, and as such it is to be judged. The descriptions are clear, brief, and well arranged. The therapeutical part is full, but is not up to the best standard—at least so we think it will appear to the American reader. Its comparatively small size and practical character will no doubt find for it a large circle of readers.

ABERNETHY ON TABLE-HYGIENE.—There are still, we believe, some apostles of rapid eating among the doctors in this country. We commend to their attention the following interview (from "Sam Slick"), which is worth a hundred lectures: "The Honorable Alden Gobble was dyspeptic, so he goes to Abernethy for advice. 'What's the matter with you?' says the doctor. 'Why,' says Alden, 'I presume I have the dyspepsy.' 'Ah!' says he, 'I see —a Yankee, swallowed more dollars than you can digest.' 'I am an American citizen,' says Alden, with great dignity; 'I am secretary to our Legation at the Court of St. James.' 'The devil you are!' says Abernethy; 'then you'll soon get rid of your dyspepsy.' 'I don't see that inference,' said Alden. 'But I tell you it does follow,' says the doctor, 'for in the company you'll have to keep you'll have to eat like a Christian.' It was an everlasting pity Alden contradicted him, for he broke out like one moon-distracted mad: 'I'll be d—d,' says he, 'if ever I saw a Yankee that didn't bolt his food whole like a boa constrictor. How the devil can you expect to digest food that you neither take the trouble to dissect nor time to masticate? It's no wonder you lose your teeth, for you never use them; nor your digestion, for you overload it; nor your saliva, for you expend it upon the carpets. You Yankees load your stomachs as a Devonshire man does his cart, as full as it can hold and as fast as he can pitch it in with a fork, and drive off. And then you complain that such a load is too heavy for you.'"

# Reports of Societies.

## NEW YORK SURGICAL SOCIETY.

*Stated Meeting, May* 24, 1881.

DR. H. B. SANDS, PRESIDENT, IN THE CHAIR.

DR. JOSEPH W. HOWE read a paper on

THE BEST MEANS FOR ARRESTING HEMORRHAGE IN EXTIRPATION OF THE TONGUE.

Special reference was made to ligation of the lingual artery near its origin as a preliminary operation, first performed by Dr. George F. Shrady, and subsequently by himself. (See MEDICAL RECORD, vol. xiv., p. 204.) According to statistics, however, as he had been able to collect them, the use of the ecraseur had given the best results.

DR. BRIDDON said that, in the execution of such cutting operations for the removal of the tongue as necessitated a transverse section far back, and in which it was considered proper to make a preliminary ligation of its nutrient artery, he had no hesitation in saying that the proper place for the application of such ligature was upon the lingual outside the submaxillary triangle, in the superior carotid triangle, between its origin and its dorsal branch. The point at which that branch is given off, and its size varied, so that occasionally it might suffice to tie within the triangle; but cases had demonstrated that it was not safe to rely on a ligature applied to that portion of the vessel when it was necessary to remove a large part of the organ.

In Dr. Stimson's case there was hemorrhage, but not of a serious character, when the posterior transverse section was made.

In a similar operation, in the same hospital, by Dr. George F. Shrady, in which he tied the lingual outside the triangle, the section of the tongue was virtually bloodless.
